The correction of this unhealthy economic situation would naturally be consolidation and concentration of production in a relatively few plants. Such a plan is impossible, however, in this industry, owing to divergence of interests and the extent to which the zinc smelteries, great individually as they are, exist as mere appendages of far greater enterprises. Elimination of surplus capacity can be brought about therefore only by the natural process of competition and the survival of the fittest. As a consequence of such constraint all smelters operated on narrow margins, and not a few were in red ink. The only concerns that are in a comfortable position are those possessing a completely integrated business, i.e., producing and beneficiating their own ore, and perhaps manufacturing products from their metal.

Attitude of Labor.—Another consequence of the severity of competitive conditions is the frantic efforts that are made by everybody to improve methods. In this effort an obstacle is the attitude of labor, which tries to seize for itself the benefit for any improvements or else opposes improvement for the sake of its own ease in working.

The electrolytic producers are immune from such obstacles, for by their process the labor requirement per ton of ore is much less than in the distilling process and the labor requirement is so organized as to be under better technical control. For this reason, among others, electrolytic production increases and thereby adds to the competition that the distillers have to meet. For brass manufacture electrolytic zinc is now especially favored, and the export trade is largely in that grade of metal.

Processes.—Electrolytic zinc is now being produced, or is going to be produced in several small works in Europe.

In American and in Australian experience an electrolytic zinc plant must be of large size in order to be profitable, but the lower wages for labor in Europe, and some other favorable factors, may lead to the enjoyment of a different experience there. In distilling, or smelting, as it is commonly called, the average cost in Europe appears to be about the same as in the United States, but the European employs many more men per ton of ore. In Germany this has been to some extent the means of affording employment during the immediate post-war period, and as industry revives more economy of labor and at the same time higher wages may ensue. Both in Belgium and Germany strenuous efforts toward metallurgical improvement are being exerted. An interesting feature of 1925 has been that vigorous steps have been taken toward increasing zinc smelting in Great Britain. Another interesting event was the negotiation by an American banking house for an important interest in Giesche's Erben, which is one of the large zinc smelters of Upper Silesia and owns the most important zinc mine in that province. The transfer to Poland of a part of Upper Silesia included all of its zinc smelteries and practically all of its zinc mines, since which time they have passed extensively into French and other foreign hands.

Conditions.—While the metallurgical division of the zinc industry was troubled in 1925 the mining division was quite prosperous. The price for zinc was high in the early part of the year. Around mid-year it fell off. In the autumn it rose to a higher level than for a good many years. Zinc mines then became very profitable.

LEAD

By Allison Butts
Professor at Lehigh University

Status of the Industry.—The lead industry is enjoying a period of prosperity. Its position is undeniably far stronger than that of copper, zinc, gold, or silver, and has been for several years. The year 1925 has been one of higher prices with continued high production levels for all the leading non-ferrous metals in the United States; but for lead the increase in price was added to a figure already well above normal, which is not true in the case of the other metals. The price of lead at New York in 1925 will average about 9.1 cents per pound, as against 8.1 cents in 1924. The 1913 price was only 4.4 cents; if that figure be increased by 60 per cent., the average commodity price increase since 1913, we arrive at a figure of 7.0 cents per pound which in a sense may be regarded for comparison as a "normal" present price for lead. As succinctly expressed by J. R. Finlay, the world is now using one-quarter more lead than in 1913 and paying a relative price one-quarter greater. Mr. Finlay's statement was made at a meeting of the New York section of the Mining and Metallurgical Society of America (*Eng. and Min. Jour.-Press*, Vol. 120, pp. 747-8), held on Oct. 29, 1925, at which there was a symposium to which was given the title of "Lead—The Precious Metal." The title was borrowed from that of a book by O. C. Harn that appeared in 1924, and its use for the subject of the meeting suggests in a figurative way the position into which the metal has grown.

Demand, Consumption, and Uses.—What are the chief causes of the high price for lead, which is now definitely established above the price of zinc whereas its level until a few years ago was always below that of zinc, and which is accompanied by a high rate of production? The causes are twofold—a strong demand and a more difficult supply, the supply being adequate only by reason of a price favorable to large production. R. M.

Santmyers notes in his review of the lead industry appearing in *The Mineral Industry,* Vol. 33, October, 1925, that of the six major lead districts on which the world has relied for the bulk of its metal, three regions have passed into a stage that presages waning supplies, this being true of Australia, of the Coeur d'Alene district of Idaho, and particularly of Spain. Lead producers at the meeting mentioned above expressed a confidence that new lead districts would be developed to supplement and supplant the old as the need arises, but none could actually name a new district to count upon. The lead industry has long been a well-stabilized one, practically free from the fluctuating periods of inflation and depression that have characterized the other metals, and the producers, alive to the desirability of maintaining such a poise, have thus far succeeded well in so doing.

Commercial Uses.—The strong demand for lead is due to activity in the leading lines of lead consumption. The lead pigments—chiefly white lead, but including also considerable amounts of red lead, litharge, orange mineral, and others—have always constituted the largest use of lead. Although relatively lead has been losing some ground in paint manufacture, the building boom has kept up the demand from this source so that in total amount consumed lead-pigments have more than held their own. There was possibly some decline in this line in 1925, as one of the leading manufacturers stated that his sales of white lead in 1925 were 15 per cent. smaller than in 1924. Building has also taken larger amounts of lead for pipe and other purposes.

The real benefactors of the lead industry have been the makers of storage-batteries and the makers of cable-covering. The former, meeting the great demand from the automobile and the radio industries, are taking twice as much lead as a few years ago and now consume almost as large a proportion of American lead as do the paint manufacturers.

Cable-covering is a good third in point of lead consumption and has been increasing even more rapidly than storage-batteries. Most of the other uses of lead have remained about stationary. In actual figures, as compiled by the American Bureau of Metal Statistics, lead was consumed in the United States in 1924 in the following amounts: for pigments, 184,000 short tons; for storage-batteries, 170,000 tons; cable-covering, 138,000 tons; bearing metal, solder, and calking, 88,500 tons; building, 83,000 tons; foil, 35,000 tons; all other uses, 123,000 tons; total, 811,500 tons.

Production.—The world's output of lead in 1925 will be a little larger than that of 1924, which in turn was easily the largest annual output ever made. The 1925 production promises to exceed 1,600,000 short tons; that of 1924 was about 1,540,000 tons, and of 1923 (the next largest), 1,367,000 tons. All the leading producing countries except Spain shared in the increase in 1925, but production in most of the minor countries declined. Figures have been issued by the American Bureau of Metal Statistics giving the approximate outputs of the principal countries for the first nine months of the year; increasing these by one-third to arrive at a twelve-month basis for comparative purposes, we have the following figures for 1925 outputs, together with the figures for 1924: United States, 630,000 tons in 1925 against 586,000 tons in 1924; Mexico, 201,000 tons against 181,000 in 1924; Australia, 160,000 tons against 146,000; Spain and Tunis, 126,000 tons against 172,000; Canada, 122,000 tons against 90,000.

The rapid growth of lead mining in Canada, due almost entirely to the activities of the Consolidated Mining & Smelting Co. in British Columbia, is one of the features of the lead industry of the last three years. The most promising new district seems to be the Mount Isa lead-silver field in Queensland, reports from which in 1925 continued to justify the hope that it would become one of the world's large producers, though perhaps not rapidly enough to more than offset the decline in the Broken Hill field of Australia.

Copper and Lead.—Production of copper has grown even more rapidly than that of lead in recent years, and the world outputs of these two metals are now practically on a par. Thus we have two metals in equal demand, but with copper selling at 14.1 cents per pound and lead at 9.1 cents.

The chief reason for this lies of course in the costs of production, which E. P. Mathewson recently quoted roughly as about 4 cents a pound for lead and 12 cents a pound for copper. It is interesting to note that the pre-war difference in price between lead and copper was about 10 cents a pound instead of only 5 cents.

Progress in Lead Metallurgy.—New departures in metallurgy are a matter of slow development rather than sudden change. Even when looking back a few years reveals a distinct difference in methods, the change in a single year may not be evident. Arthur B. Parsons wrote early in 1925 (*Eng. and Min. Jour.-Press*, Vol. 119, pp. 876-83) an account of a tour through Western lead smelters, and the new things that he noted were nearly all the result of developments that have been in evidence for several years. Chief among them are: (1) increased use of mechanical handling devices; (2) improved roasting, made necessary especially by the greater zinc content now met with in lead ores, and done in most plants in two stages, the final roast being on Dwight-Lloyd sintering machines, taking the sulphur below 4 per cent., and the preliminary roast either in multiple-hearth shaft roasters or on Dwight-Lloyd machines; (3) more thorough smoke treatment, especially with more and improved Cottrell apparatus; and (4) special plants for recovery of by-products, particularly arsenic.

Perhaps the most important recent development in lead metallurgy is in the use of selective flotation, separating zinc from lead and recovering both metals, thereby making the increasing zinc content of Western lead ores an asset instead of a total liability. Encouraged by the success of the Consolidated Mining & Smelting Co. with their Sullivan mine, other large companies are making a definite bid for complex zinc-lead ores such as were formerly fought shy of. During 1925 a flotation plant was installed at Berkeley, Calif., to treat lead-zinc-silver ores on a custom basis. A 250-ton flotation plant is planned for treating complex ores at Leadville, Colo.

Processes. — Another significant trend is the increasing interest in hydrometallurgical methods for lead. The Tintic Standard mill at Harold, Utah, and the Tainton process plant at the Bunker Hill & Sullivan mine at Kellogg, Idaho, both leaching lead with brine, were joined in 1923 by a new brine-leaching plant of the Combined Metals Co. at Bauer, Utah. The last named has been described by Arthur B. Parsons (*Eng. and Min. Jour.-Press*, Vol. 119, p. 55). Testing of the Coolbaugh sulphating process was also described by Parsons (*loc. cit.*).

The Chief Consolidated Mining Co. is successfully treating lead ore by an oxide volatilization process at Eureka, Utah, and a number of other plants are working alone this line with semi-commercial units.

In lead refining the Harris process and the Colcord process are recent developments of importance. These are substitutes for the usual furnace process of softening lead prior to desilverization, both employing the addition of certain chemical refining agents to the molten lead at low temperatures. Copper is drossed by the addition of sulphur, and caustic soda is then added. The Harris process also utilizes niter-cake for a further separation, employing special apparatus. The Colcord process is somewhat less pretentious, but has the advantage of not requiring extra apparatus. Advantages of these processes over furnace softening are saving of time, saving of fuel, saving of metal, and separate recovery of by-products.

The Betts process of electrolytic refining of lead continues to be successful, and the plant at Trail, B. C., has been enlarged, so that during 1925 it was turning out 9,000 to 10,000 tons of lead per month.

STATISTICS OF MINERAL PRODUCTION

By Frank J. Katz

Engineer in Charge, U. S. Bureau of Mines (1919-1924)

WORLD'S PRINCIPAL MINERAL PRODUCTS

(In metric tons of 2204.6 pounds)

Compiled by R. M. Jones

DIVISION XX

MANUFACTURES

GENERAL CONDITIONS

By Lawrence B. Mann
Acting Chief, U. S. Division of Statistical Research

Summary of Recent Developments in Manufacturing.—Output of American factories reached a record total in 1925, as a result of the general prosperity of both the rural and urban population. An accumulated demand for motor vehicles and for additional housing accommodations resulted in a record output of automobiles, rubber tires, cement, brick, and many related products. This increase in production has been accompanied by some increase in stocks of both raw materials and finished products, and by an upward trend of factory employment. The number of wage earners in manufacturing industries has not, however, expanded as much in recent years as the volume of output, because of a substantial increase in the efficiency of factory operation. This increase output per wage earner has been obtained largely by the installation of new machinery operated by electric motors which receive their current from central power plants. Changed conditions in supply of both labor and power have resulted in a wider dispersion of manufacturing industries throughout the United States. As a result, there has been an exceptionally high rate of manufacturing growth in the Pacific and mountain states, while the largest absolute increase in production has occurred in the more thickly populated states of the Middle West.

Manufacturing During 1925.—Manufacturing increased substantially in volume during the first quarter of 1925, and the March output was larger than for any month of 1924, almost equaling the record-breaking totals of the spring months of 1923. Production was maintained at a high and unusually steady rate throughout the four following months. A moderate seasonal reduction occurred in August, but this was followed by a slight expansion in September. The aggregate output of American factories during the first nine months of 1925 was larger than in the corresponding period of any earlier year, exceeding the production of 1924 by 12 per cent., and that of 1923 by one-half of one per cent.

The chief reasons for this tremendous 1925 output of manufactures were the improved buying power of American agricultural sections and the unsatiated demand for automobiles and new buildings. Large European demand for cereals from America during the crop year 1924-25 caused a marked increase in agricultural prices and in the purchasing power of American farmers. The improved financial status of the rural communities was reflected in a 13 per cent. increase of mail order sales and an enlarged demand for a very varied list of manufactures which in turn caused increased factory employment and an expansion in urban buying.

As in the immediately preceding years, the motor vehicle and construction industries benefited in the most marked way from the general prosperity of the people of the United States. During the first three quarters of 1925, a total of about 2,790,000 passenger automobiles and trucks were produced, an increase of 7 per cent. as compared with the previous year (though slightly less than in 1923), and there was little evidence that the industry was approaching a point of saturation. A growing demand for motor busses in all sections of the country and an increase of 66 per cent. in the value of our exports of automobiles and chassis were factors contributing to this enormous output. Tire production also showed a large increase in 1925 due to the increased number of cars in operation and the widespread demand for balloon types as replacements for high pressure tires.

The volume of building for which contracts were awarded during the first eight months of 1925 was larger than in the corresponding period of any earlier year, being about 18 per cent. more than in 1924. This huge volume of new construction necessitated an increased production of lumber, cement, and other building materials.

Expansion.—Increased production of automobiles and new buildings, together with the improved condition of the farmers, has resulted in a moderate expansion of output in many manufacturing lines. Iron and steel production reached a very high level in the early months of 1925, declined during the spring and summer, and expanded again in the fall. Production of textiles and paper showed a rather similar trend, but were much less active in the first part of the year and had less of a revival in the autumn. Of the textiles, cotton and silk fabrics were produced in larger volume than in 1924, while there was little change in the output of woolens. Rayon (artificial silk), on the other hand, has shown a remarkable gain in popularity and was used in larger quantities than in any earlier year. The leather and shoe industries which have been depressed for several years had only a moderate increase in activity in 1925, though a considerable demand developed for staple lines of shoes. Output of manufactured food products showed only a moderate increase during the current year, though sugar meltings and cottonseed oil production were much larger than in the two preceding years due to the large sugar and cotton crops. Of the other industries ship-building was at a very low ebb and production of railway locomotives was drastically curtailed.

The expansion in manufacturing activity during the past year has been accompanied by a considerable increase in the stocks of certain raw materials at factories—notably cotton, silk and wood-pulp. Stocks of raw wool and of iron ore, on the other hand, were somewhat smaller in the summer of 1925 than a year earlier. Increased demand for raw materials has caused some advance in their price; the most striking appreciation has occurred in the price of crude rubber which was almost three times as high in September as a year earlier due to the increased demands from factories and the curtailment of the supply by British planters.

Stocks of finished manufactures have also increased moderately during 1925 and at the end of August were about 12 per cent. larger than a year earlier. Increases were most general among the construction materials and were particularly large for the various types of enamel sanitary ware. Stocks of manufactured foodstuffs, on the other hand, were substantially smaller than in 1924; reductions were most noteworthy for stocks of meat products, butter, and wheat flour. In spite of the increase in manufacturing output and in the volume of finished stocks, the unfilled orders on the books of manufacturers were substantially larger at the end of August, 1925, than a year earlier. Increases in unfilled orders were general among the building materials and the finished steel products.

Employment.—The expansion of manufacturing during the past year has been accompanied by an increase of about 6 per cent. in the volume of factory employment. The fact that employment has increased relatively less than the volume of output is explained in part by an increase in the average working hours and in part by a greater efficiency of operation which will later be discussed in more detail. The groups of industries which had made the largest additions to their working forces in August, 1925, as compared with a year previous, were automobiles, nonferrous metals, chemicals, iron and steel, textiles, and leather. Plants manufacturing food products and tobacco products were the only ones which reduced their forces during this period. Pay-rolls in August were 8 per cent. larger than a year earlier, the increases being particularly pronounced in the nonferrous metal, automobile, lumber and steel industries. Changes in pay-rolls during the past year have been primarily due to increases in number of employees and increases in amount of full-time operation of mills, as the changes in wage rates have been scattered and relatively unimportant.

The generally healthy condition of manufacturing industry in 1925 is indicated by the fact that failures of manufacturers during the first three quarters of the year were 5 per cent. fewer in number and 47 per cent. smaller in total liabilities than in the corresponding period of 1924. The position of the manufacturing industry in this regard has been particularly favorable, as both the number and liabilities of failures for trade establishments, agents, and brokers have increased during the current year.

The Growth of Manufacturing Industry (1849 to 1923).—The United States is at present the greatest manufacturing nation in the world. Some idea of the stupendous growth of manufacturing industries which has transformed the United States from a primarily agricultural to a predominantly industrial nation may be obtained from an examination of the following table comparing the results of the 1923 census which have just become available with those of earlier years:

MANUFACTURING GROWTH, 1849 TO 1923
(All figures in thousands.)

	Primary Horsepower	Wage Earners	Wages	Value of Products	Value Added by Manufacture
1849	*	957	$ 236,755	$ 1,019,107	$ 463,983
1859	*	1,311	378,879	1,885,862	854,257
1869	2,346	2,054	620,467	3,385,860	1,395,119
1879	3,411	2,733	947,954	5,369,579	1,972,756
1889	5,939	4,252	1,891,220	9,372,379	4,210,365
1899	10,098	4,713	2,008,361	11,406,927	4,831,075
1909	18,675	6,615	3,427,038	20,672,052	8,529,261
1914	22,437	7,036	4,078,332	24,246,435	9,878,346
1919	29,505	9,096	10,533,400	62,418,079	25,041,698
1923	33,094	8,779	11,009,297	60,555,998	25,856,280

* Data not collected.

These statistics are not strictly comparable, as hand and neighborhood industries are included in the data for years prior to 1899 and automobile repair shops and establishments doing a business of less than $5,000 per annum were not included in 1923. Both of these major changes in scope of the manufactures census tend to minimize the growth of the industry in making comparisons. A comparison of the figures for 1923 with those for 1849, nevertheless, show that in less than three-quarters of a century the number of persons employed in American manufacturing industries has multiplied by over nine times, while the value of their product has increased sixty times. During the twenty-four years ending in 1923 primary horsepower engaged in manufacturing increased 228 per cent.; the number of wage earners, 86 per cent.; the total value of products, 431 per cent.; and the value added by manufacturing, 435 per cent.

Price.—Comparison of the results of the 1923 census and the 1914 census is particularly significant, as it indicates the permanent growth of industry during the war period. As there were very substantial changes in prices during this period it is necessary to make some adjustment for this factor in comparing figures expressed in values. Adjustment of the increase of value added by manufacturing to allow for increases in average prices of manufactured products indicates that there was a 58 per cent. increase in the quantitative output of manufactures during these nine years. All of the sixteen major groups of products shown by the census except tobacco manufactures have increased their output; the principal increases occurring in the transportation group which includes automobiles and the rubber products group which includes tires. Other groups which showed more than the average increase in output were textiles, iron and steel, machinery, railroad repair shops, and miscellaneous industries.

Increase in Efficiency of Manufacturing.—Changes in the general efficiency of manufacturing industry may be estimated by dividing the value added to materials in the process of manufacture by the number of wage earners. As the value added by manufacture represents not merely the product of labor but also that contributed by managerial ability and machinery, a quantitative increase in output per wage earner may represent an increase in efficiency in any or all of these factors. The average value added to materials per wage earner employed was about $1,400 in 1914, $2,750 in 1919, and $2,950 in 1923. If the increase from 1914 to 1923 be corrected for price changes, it indicates a quantitative expansion in per capita output of nearly 26 per cent. The increase in per capita output during the post-war years has been particularly notable, as pressure for immediate production during the war years tended to hamper efficiency of operation.

One reason for the increased output of factories per wage earner has been the increase in the amount of machinery used and the constant substitution of improved types of machinery. In the period from 1919 to 1923 the physical production of factories was increased by about one-fifth, while there was an actual decrease of 3½ per cent. in the number of wage earners employed. During this period the amount of primary horsepower of factories was increased by 12 per cent. Furthermore, the entire increase in the amount of power apparatus was in the form of electric motors which received their current from central power plants and there was an actual decrease in the power provided by local plants.

Changes in Geographic Distribution of Manufacturing.—In the middle of the last century most of the manufacturing of the United States was concentrated in the northeastern states, but for many years it has tended to spread both to the west and the south. A tendency to concentrate an industry in one section has been succeeded by a tendency to distribute many industries in widely separated areas. The steel industry which was once largely concentrated in the vicinity of Pittsburgh, now has other large manufacturing centers at Chicago and Birmingham. The cotton textile industry which was once confined principally to New England is now rather evenly divided between the South Atlantic and New England states. The shoe industry has shown a decided tendency towards localization and has now become of substantial size in New York, Missouri, and Ohio, as well as in New England. On the other hand the recently developed automobile industry has been concentrated almost exclusively in Michigan. This decentralization of industries geographically is favored by the wide area of the United States, the development of many large local markets, and the greater flexibility of labor supply obtained by locating plants in many different sections. It is also made more feasible by the substitution of electric power for water-power.

An analysis of census statistics by districts indicates that the East North Central states have had the largest actual growth of manufacturing during the last decade. As a result of the tremendous growth of the automobile industry in Michigan, the rubber-tire industry in Ohio, the steel industry on the shores of the Great Lakes, and the machinery industry in many separate centers, the number of wage earners employed in these states has increased 42 per cent. and the amount of primary horsepower 67 per cent. from 1914 to 1923. Due to the pronounced growth of steel, canning, motion picture, and other manufacturing industries in California and of the lumber industry in the northwest, manufacturing has shown an even larger relative growth in the Pacific states than in the East North Central group, but the total size of the industry in that section is still very much smaller. The mountain states have also shown a substantial growth in manufacturing activity, though their aggregate output is still small. In the various sections of the South manufacturing has shown about the same growth as for the nation as a whole, due largely to increased output of cotton textiles and lumber.

Even in New England, which has suffered from the competition of other sections in the textile and shoe industries, the number of factory wage earners in 1923 was 10 per cent. and the amount of primary horsepower 33 per cent. more than in 1914.

SHIPBUILDING AND SHIPREPAIRING

By Peter Bain

Editor of Bain's Marine Annual

Depression.—The year 1925 had scarce dawned when the opinion was expressed by a gentleman close to ships and shipping that American shipbuilders and shiprepairers, and American shipowners, would have great difficulty in surviving a repetition of 1924. Shipbuilding and shiprepairing, the world over, had reached a stage of depression hitherto unknown in either industry—plants were being sold and dismantled, while many remained unsold—this, together with a hugely overbuilt condition everywhere staring one in the face, otherwise than lining up with those of the pessimistic turn of mind, entailed the drawing upon one's resources of optimism nigh to the dregs. It was January 1, 1925. We were looking forward then.

Bright Spots.—Looking back over 1925, we find many of our fears and forebodings to have been groundless. The United States of America may well be placed on record as one of the bright spots. It is true that our record is still far removed from normal in the matter of tonnage under construction, launched and completed, and that as regards vessel size and type, machinery installation, general equipment and outfitting, we may have done nothing very outstanding in either of the directions indicated, or compassed any very spectacular achievement.

Looking back, it may be claimed, however, that we have fared very well and have done very well, everything considered and, looking forward on the threshold of 1926, it is not now a question of surviving another such year; rather is it, how close to normal will the next twelve months bring us. It is, of course, true that contracts for both new construction and repair work have been and are still being secured in the face of keen competition and, having regard to the commendable effort made and determination displayed by plant executives to retain their expert staffs and skilled employees against the certain advent of better times, it is no secret that profits have been slim and not always realised.

Public Demand.—American shipbuilding activity, aside from that pertaining to vessels for Great Lakes and Inland Waterways Services, which is never far from normal, has arisen almost entirely from a demand that had been making itself felt even during 1924—the demand, both passenger and freight—for bigger, faster, more modern and therefore more comfortable and more luxuriously equipped and furnished coastwise and intercoastal liners. In a word, there was needed because desired, similar and equal travel conditions on a trip to South Atlantic, Gulf, West Indies and Pacific Coast ports as the conditions available on the big trans-Atlantic liners.

Domestic and World Figures.—On January 1, 1926, American shipyards were building or under contract to build for private shipowners 186 steel vessels of 219,793 gross tons compared with 161 steel vessels of 177,166 gross tons on January 1, 1925. On January 1, 1926, 36 wood vessels of 11,756 gross tons were building or under contract to build for private shipowners, compared with 13 wood vessels of 6,303 gross tons on January 1, 1925. The totals above relate to vessels of 100 gross tons and over, the distribution of the work embracing some 30 plants of various capacities—inland and coastwise—Atlantic, Gulf, and Pacific.

Output.—According to Lloyd's Register of Shipping, for the year ended December 31, 1925, there were launched from American shipyards, 20 steam propelled steel vessels of 95,673 gross tons, 25 motor propelled steel vessels of 42,685 gross tons, 3 motor propelled wood vessels of 578 gross tons, 25 steel sailing vessels and barges of 25,086 gross tons, and 23 wood sailing vessels and barges of 11,396 gross tons, making a grand total for the twelve months' period of 72 vessels of 156,248 gross tons. These figures compare with 15 steam propelled steel vessels of 67,594 gross tons; 20 motor propelled steel vessels of 39,383 gross tons; 2 motor propelled wood vessels of 550 gross tons; 23 steel sailing vessels and barges of 22,086 gross tons, and 19 wood sailing vessels and barges of 10,450 gross tons, or a grand total of 78 vessels of 140,063 gross tons for the year ended December 31, 1924. World launchings for the year ended December 31, 1925, totaled 1,025 vessels of 3,065,288 gross tons, compared with 924 vessels of 2,248,351 gross tons as of December 31, 1924.

Sources of the 1925 Activity.—As with shipbuilding, so with shiprepairing, the gratifying measure of prosperity enjoyed has been wholly of a domestic and national character. Of course, and having in mind the large number of foreign ships trading to and from our ports, there have been the normal meaty pickings, arising from drydocking, scraping and painting, rough weather buffeting, strandings, collisions, etc. The reconditioning of vessels for services other than which they were originally designed for was rather above normal, and consisted of new adaptations of the passenger accommodations and freight spaces, together with the substitution of oil-burning equipment for that of coal, to meet special service demands, the most spectacular of which was the all-water route between New York and Miami, Fla.

The fact that during 1925 we did not build for foreign account, and that all new construction ordered was for account of American ownership, constitutes a circumstance by no means novel. Other things being equal, American costs are high comparatively, and naturally when competition is thrown open to the shipbuilders of the world, we lose out. With the exception, however, of tankers, a number of which are in various stages of construction in British and Continental yards, it would appear that for other class and type vessel, comparative costs have reached a point where home builders may reasonably be favored. An interesting feature of the position indicated was the decision of the Eastern Steamship Lines (Coastal), following an investigation of costs abroad by its President and Mr. Theodore E. Ferris, the well-known naval architect of New York City, to build its two new vessels at home, the Wm. Cramp & Sons Ship & Engine Building Co., Philadelphia, securing the order.

The Liner "Malolo."—This firm also has under construction the big liner *Malolo* for the San Francisco-Honolulu Service of the Matson Navigation Co. Gibbs Brothers, naval architects and consulting marine engineers, are the designers of this vessel, which is expected to rank among the finest of our home-built liner products when she goes into commission. Contract for her construction was approved by the United States Shipping Board on December 16, 1924, the cost to be $6,560,000. Approval of the Board was necessary under Section 23 of the Jones Act, which provides the setting aside of an amount equivalent to excess and war profits taxes for the purpose of building in American shipyards, new vessels of a type and kind approved by the Board, two-thirds of the cost of which vessels shall be paid out of ordinary funds or capital of the person having the vessel constructed.

The *Malolo*, which is expected to go into service early in 1927, will be 582 ft. long, will displace 22,050 tons, and will develop 25,000 shaft horse power through steam turbine driven twin screws, the latter enabling a schedule speed of 21 knots being maintained on the run and something substantial to spare. She will have capacity for 680 first class passengers and will make two round trips a month. The *Malolo* will establish a new standard—the big trans-Atlantic liner standard—in comfort and luxury in Pacific Ocean travel. A cruiser stern, two pole masts and two short but imposing stacks, well raked, will give the vessel at once a dignified and powerful appearance.

Big Panama-Pacific Liners.—The third and fourth quarters of 1925 showed a good deal more activity on the part of steamship owners in the matter of fleet additions and therefore in the placing of orders with shipbuilders. The most noteworthy order placed was that for a new liner by the Panama-Pacific Service of the International Mercantile Marine Co. Announcement of the placing of a contract with the Newport News Shipbuilding & Dry Dock Co., for the first of a fleet of three intercoastal passenger liners was made during the last week in October, thereby signalising the first move in a construction program which will involve the expenditure of $21,000,000.

In general design, as well as in details of layout and construction, the new liner will differ from all other vessels now employed in American coastal or intercoastal trade. Her design is based on the new "Minne" class of the Atlantic Transport Line —the *Minnewaska* and the *Minnetonka*, plying between New York and London, but elaborated as to deck plans and cabin arrangements to meet the exacting requirements of service in both tropical and temperate climates at all seasons of the year. The specifications call for a passenger liner of 22,000 tons gross register, a loaded displacement of 31,000 tons, a speed of 18 knots, derived from machinery installation of 18,000 horse power developed through steam turbines coupled to General Electric Co generators, operating twin screws. Oil fired, water-tube boilers, twelve in number, will supply steam to the turbines. This type of propelling machinery, although well tested through installation in many vessels of the United States Navy, is somewhat of a novelty in merchant ships.

Smartness of appearance and a suggestion of tropical service will be accentuated by a white painted hull and superstructure. The new ship will have eight decks, a cruiser stern, a single stack, be 600 ft. in length, 80 ft. beam and 52 ft. depth. There will be 147 staterooms in the first class and 110 in the tourist class. The public rooms will be finished in American walnut and white, in period styles. Staterooms will all be of the outside type in both classes, while deck spaces for promenading and sports will be equally spacious as on the big trans-Atlantic liners. Novel features in the vessel's construction will embrace large side ports through which automobiles carried by passengers as baggage can be driven on board. Delivery from the hands of the builders is expected in the Fall of 1927.

Additional Orders for Coastwise Vessels.—Notwithstanding the considerable number of new vessels placed in coastwise service during the past two years, all of which were, of course, built in American yards, orders still continue to be placed for more, the Clyde Line being conspicuous in this direction. Replacement of some of its vessels, unfortunately destroyed by fire, has been promptly undertaken, contracts having just recently been awarded the Newport News Shipbuilding & Dry Dock Co., from whose yard the trio of palatial liners—*Cherokee, Seminole and Mohawk*—were also turned out and placed in commission during 1925.

Government Encouragement.—Advantage is being taken in more generous measure by private shipowners of the Government Construction Loan Fund and, as time goes on, with the period of its availability extended, as it should be, the value of such a fund in building up a substantial privately owned American Merchant Marine and maintaining it at the highest pitch of efficiency, not only in coastwise trade but in international trade as well, will become decidedly more marked in achieving the objective for which it was instituted. Section II of the Merchant Marine Act of 1920 as amended by the new law approved June 6, 1924, provided "That during a period of five years from the enactment of the Merchant Marine Act, 1920, the Shipping Board may annually set aside out of the revenues from sales and operations a sum not exceeding $25,000,000, to be known as its Construction Loan Fund." This $25,000,000 a year, while available for private shipowners, "citizens of the United States," authorized, through Section II of the new law, the Shipping Board also to utilize the fund for the reconditioning of its own vessels and equipment with "the most modern, the most efficient and most economical" types of internal combustion engines. A start has been made in this direction.

Therefore, while the Construction Loan Fund, with its many advantages, had been available in modified form for several years, comparatively few steamship owners had made use of it. Aside from some light draft craft for the Great Lakes, the only vessels built and in commission, building or contemplated, were the *George Washington* and *Robert E. Lee* for the Old Dominion Line, the *Coamo* for the New York & Porto Rico Steamship Co., and the *Cherokee, Seminole* and *Mohawk*, for the Clyde Line, all of them combination passenger and cargo carriers, and all placed with the Newport News Shipbuilding & Dry Dock Co.

Other New Construction Features.—New construction for coastwise account while filling a large place has been otherwise aided in making the 1925 record so favorable and the immediate future outlook equally so. Harbor craft, consisting of tugs, barges and ferryboats have been ordered, built and completed, for duty in the territorial waters of many of our principal seaports, the number and variety being such as to warrant one in saying that the output has been somewhat ahead of normal and the ownerships involved about equally distributed between private enterprise, municipalities and railroads. On the Great Lakes, it may be said that new construction and repairs have kept the various yards reasonably well employed, especially when one considers that no great deviation is noticeable in the output or its nature and variety from year to year.

The many developments taking place in the spheres of shipbuilding and shiprepairing, together with the advances being recorded in ship propulsion mediums, ship equipment, and freight handling apparatus, have been responsible for much of the new construction relating to harbor craft, this being generously apparent in Diesel engined tugboats, Diesel-electric tug and ferry boats, with and without auxiliary steam apparatus, water-tube boiler installations with oil burning provision, increased and improved service efficiency being the inevitable outcome. A development of the past year in our midst was the decision of the Marine Department of the New York Central Lines to have ten barges built on the Ellis Channel System, a number of which are already in commission and giving, we understand, complete satisfaction. Low first cost, strength, and economy of material are among claims made on behalf of the system.

Sale to a Foreign Concern.—Concluding this brief review, it may be said that the transfer of the plant of the New York Shipbuilding Corporation, at Camden, N. J., was an event of rather more than passing interest, indicating as it did that the new owners—Brown, Boveri Co. of Switzerland—see great possibilities here for enlarging their diversified and far flung activities. Ships are more or less always needed for special services, besides, in this day of new type hulls, new systems of constructional detail, new propulsion mediums, etc., changes are taking place oftener and generally more suddenly than heretofore, all of which implies that existing vessels get rapidly out of date and must be replaced by their owners if they would hope to continue in business. An earnest and praiseworthy attempt is being made to still further develop our inland waterways, a consummation in its intermediate stages which will certainly bring "grist to the mill" of the shipbuilder the shiprepairer and the marine engineer. The New Year, 1926, is already tinged with optimism, born of a confidence based on sound reasoning, careful analysis and much fact.

INVENTIONS AND PATENTS

By Wm. A. Kinnan

First Assistant Commissioner of Patents

Output of Patents.—Our people obtain far more patents than any other people on earth. During the year 1925 over 80,000 applications were filed in the Patent Office at Washington, and over 45,000 patents were granted. This very nearly broke the record as to applications and did break it as to the number of patents granted.

These patents relate to the production of almost everything man makes and uses. Reading, through them, the story of the progress of the year, they show that the great trend has been toward refinements and perfections, rather than toward anything startlingly or fundamentally new. The cotton gin, the sewing machine, the telephone, are fundamental inventions, which affected and changed the entire economic and domestic habits and modes of life the world over; and the making of each was followed by a vast number of auxiliary or dependent inventions in the nature of improvements, refinements and perfections. The past year has produced no invention of this fundamental nature, but those which have been made are, collectively, of very great importance. Patents have been granted during the year 1925 relating to all the matters hereinafter noted, although the inventions in some instances were made and the applications filed prior to this year.

Broadcasting. — The broadcasting station has come in for some suggested improvements in regulating its oscillator frequency by means of the piezo-electric crystal; also efforts have been directed to the adaptation of the antenna, so it will more efficiently radiate a band of such width as to accommodate telephony. Further, perfections in the transmission from long-distance telephone wires to widely separated broadcasting stations have been made so that the music or a speech from a single point may be simultaneously transmitted by wire over considerable and different distances to a larger number of broadcasting stations located in as many different places or cities. Since there are now only about eighty-nine paths, or channels or wave lengths, which are available for use without prohibitive interference, and some 600 public-serving broadcasting stations, a remedy must be found. Increased selectivity and band range of receiving sets or conjoint simultaneous operation as a unit of a large number of broadcasting stations from a common source and on a common wave length would seem about the only solution if more broadcasting stations are to be permitted. Efforts of inventors have been directed along both these lines. Transmission and reception from moving vehicles have been pretty well worked out. The radio receiving set has come in for a good deal of attention. The so-called neutrodyne receiver has been improved in the matter of its amplification of received energy; some attempts at providing a calling system for a receiving set have been made, and also for the better reception of continuous waves without the use of the heterodyne principle. Efforts have been made to prevent local interference between transmitting and receiving systems of duplex type. Means have been devised for supplying the radio tubes with current from the lighting or other power circuits available in homes. Attempts to eliminate static, strays, and the phenomenon of "fading," especially with short wave lengths, have been made. A very "hard" or "high" vacuum tube has been recently patented.

X-Rays.—In the X-ray art, better regulation has been obtained whereby better photographic effects are secured. Apparatus for determining the composition of minerals through diffraction of X-rays and securing photographic records thereof and arrangements looking to the elimination of objectional corona effects have been made.

Aircraft.—In connection with aircraft, advances have been made in variable camber wing planes. Increased strength, lighter construction, decreased liability of fire and greater flying range have been secured by the more complete adoption of all-made structures having internally trussed box-girder wing planes with wing enclosed power plant and load space. There has been a reduction in the necessary run or take off in launching. Progress has been made in the helicopter type of aircraft and the overcoming of some of its stabilizing and steering problems, and hydroairplanes have been much improved. Some advance has been made in airplane gun mounts and in the provision for central, stabilized, electric, gun fire control. Smoke screen producers have received some attention, as have mooring masts for the huge, gas-inflated type of air vessel.

Moving Pictures.—Regarding improvements in and relating to the fascinating procedure of making moving pictures, efforts have been directed to producing moving picture machines which will reduce the cost of making the pictures; to overcoming defects in the continuously moving film type of machine; to obtaining better stereoscopic effects in cinematography; to projecting color motion picture films at a speed nearer that of the black and white pictures; and to the saving of film by stopping it while projecting titles. Pictures are more cheaply produced by improvements in combining the natural with the artificial, by the use of painted glass foregrounds, miniatures, models, and by optically blending scenes and masking off areas for subsequent exposure on the same film. In stereoscopic cinematography steps have been taken to avoid the use of the synchronized shutter or anaglyphic viewing device by each observer and this avoids the cumbersome, expensive installation formerly found necessary. The quick "framing" of motion pictures has contributed to improved registration.

Automobiles.—In automobiles the advances have been in reliability, longer life and better use of power. Inventors have given heed to keeping the lubricating oil in the crankcase free of grit, dirt, metal-dust and other bearing-injuring impurities; the carbureter and its auxiliary charge-forming devices have taken on some further refinements, particularly to prevent the carrying of liquid or unvaporized gasoline into the engine cylinders and providing for preheating the charge mixture. In passenger automobiles, safety and comfort to the occupants and longer life to the car have been sought by providing against headlight glare and securing clearer vision in closed cars, by the design of steering gears suitable for balloon tires, and by so mounting the engine and transmission as to reduce vibration. The patent for the balloon tire was issued in 1925, although the invention was made, the application filed and the tires widely used long before. Further refinements have been made in the disk wheels. In vehicles having six or eight wheels, as in heavy busses and trucks, means for flexibly and yieldingly mounting, connecting together and driving the two rear axles, as well as steering gear for both front and rear axles have been provided. The arrangements whereby tractors both draw and steer trailers have been improved and the range of utility of the tractor has been increased. Quite a number of inventions have been directed to the prevention, by giving some sort of notice or warning, of the very enormous waste incident to carelessness or forgetfulness of car users whereby tires are used when under-inflated, and cars not given attention as to oil, grease, battery-filling, water in radiator, etc.

Steam Engines.—Here the constant tendency has been to higher steam pressures, the more economical production of steam and its more efficient utilization, especially of the exhaust.

Railway Rolling Stock.—In this field the locomotives have continued to grow larger and heavier and new refinements and improvements have been necessary. Boosters or supplemental power devices for them have been much improved, as have also steam turbine locomotives, a combined gas and electric type and a gas and Diesel motor type. Regarding the car structure, the articulated type of train wherein adjoining car ends are carried upon single trucks has been practically perfected; while cast and sheet steel railway truck frames; sheet steel ends for freight cars; a constant increase in the size of freight cars, seventy tons now being standard with one hundred ton cars proposed; higher spring capacity to reduce bumping, jolting and consequent track injury and the harmful effects upon merchandise are some of the further improvements devised. Automatic train stop apparatus functioning in accordance with traffic conditions has been made more reliable, while block signaling systems without make and break contacts have been perfected.

Oil Refining.—In the mineral oil field, progress has been made in both processes and apparatus of the tube and drum type in the high pressure pyrogenesis of hydrocarbon oils. The refluxing of the cracked vapors improves the character of the distillate, a notable step being the returning of part of the final distillate to the reflux condenser. There has also been devised the plan of splitting the raw feed into two streams, sending one direct to the cracking coil while using the other as a refluxing medium. In topping oils by heating in tubes, the principle of the countercurrent travel of the oil and the combustion gases, to prevent excessive heating has been utilized; the employment of mercury vapor as a heating means in oil cracking processes whereby hot spots in the still are said to be avoided has been proposed and inventors have sought the substitution of chemical dehydration of petroleum emulsions for the laborious and expensive processes involving physical, mechanical and electrical means previously used.

Metallurgy. — Considerable progress has been made in the field of alloys, particularly in the production of special steels, and in reducing the cost of manufacturing stainless steels. Chromium and cadmium plating has been advanced as has the process of and means for centrifugal casting. Improved methods and means for casting aluminum and its alloys have been invented.

Building and Materials.—In building, the trend has been marked toward the substituting of concrete, metal and composition for brick, wood and slate, with a gain in cheapness of material and saving of labor. As a result inventors have considerably improved building blocks and slabs, plaster and insulation boards which are much used. Interlocking flexible shingles and artificial shingles have been more nearly perfected, while the tendency to build warmer houses is seen in the improvement in the means to insulate buildings with sheathing, hollow wall structures and metal weather strips.

Housekeeping. — For the busy housekeeper inventors have been active in making minor improvements. Heating, cooking, cleaning and laundry work by utilization of electricity have been carried nearer to a maximum of efficiency and satisfaction. Safety devices of various kinds to prevent accidental injury to unskilled or careless operators, especially in connection with the heavier domestic machines, such as washing, wringing, and ironing machines, have been also brought out recently.

Agriculture.—In the agricultural field where greater use of machinery is compelled by reason of the scarcity of labor, many small refinements have been produced. Dry harvesting mechanisms which harvest the grain while leaving the stocks to be later ploughed under have been further perfected, while seed and grain saving machines, and combined tractors and harvesters have been made more satisfactory and reliable in operation.

Mining and Oil Wells.—In coal mining operations, chain cutting machines for cutting long walls and delivering the coal, broken to desired sizes, to cars or trucks in one operation have been made more successful. Some attention has been given to means and methods for clearing out old oil wells and making them again productive. These efforts have been generally directed to getting out the solids and paraffin at the bottom of the well.

Office Machines.—For the business and professional man, inventors have sought to produce a smaller, more readily portable typewriter which possesses all the functions of the standard machine. Also the complete bookkeeping machine which types, computes, manifolds, checks error by locking up when error is made, has been brought nearer final commercial perfection.

Summary.—These are some of the more important contributions of inventors to American prosperity, comfort and convenience made during the year 1925. The list could be indefinitely prolonged. Each inventor has added his contribution, even though individually small, to the great sum total that makes our people, in automatic machinery, in labor saving machinery, in industrial output per man, the leaders of the world.

ADMINISTRATION OF THE TARIFF

By Ernest W. Camp
Director of Customs, Treasury Department

Customs Districts. — There are forty-seven collection districts of the United States, which include one each in Alaska, Hawaii and Porto Rico. These districts contain three hundred ports of entry, one port in each district being designated as the headquarters port, at which port the Collector of Customs, who is the principal customs officer of the district, is stationed.

Appraisers of Merchandise are designated and assigned to sixteen of the larger headquarters ports. At other ports certain officers of the Collector's force are designated acting appraisers.

Surveyors of Customs are assigned to the ports of Portland, Maine, Boston, New York, Philadelphia, Baltimore, New Orleans and San Francisco, and Comptrollers of Customs to the ports of Boston, New York, Philadelphia, Baltimore, New Orleans, Chicago, and San Francisco.

Duties.—Although Customs is one of the oldest branches of the Government, popular conception of the functions of customs goes little beyond the apprehension of smugglers and the examination of passengers' baggage on trains and piers. Duties collected on passengers' baggage, however, amounts to only three-fifths of one per cent of the total customs receipts. Customs receipts for the fiscal year 1925 were $548,521,794. Of this sum $3,399,583 resulted from baggage examinations and $28,484,808 from importations through the mails, while over half a billion dollars was collected on cargo and freight importations.

Manner of Entry.—All imported merchandise, whether dutiable or free, is required to be submitted to customs for examination. If the value of an importation exceeds one hundred dollars a formal entry thereof must be made. Certain exceptions to this requirement are set forth in the Tariff Act of 1922 (Sec. 498), the principal exception covering "articles carried on the person or contained in the baggage of a person arriving in the United States."

Merchandise may be entered for consumption; for warehouse; for transportation and exportation; or for immediate transportation without appraisement. A consumption entry is the usual form and is used in cases where it is desired to pay the duty on the arrival of the importation at the port of entry and to secure delivery. If immediate possession of the merchandise is not essential and the importer desires to postpone the payment of duty, a warehouse entry may be made. Under this form of entry, the merchandise is sent to a bonded warehouse and duty is not paid until withdrawal therefrom. Merchandise remaining in bonded warehouse for more than three years becomes abandoned to the Government and is sold at public auction. An entry for transportation and exportation permits merchandise to be shipped in bond through the United States to a foreign destination without the payment of duty; and the immediate transportation entry permits an importation to be shipped in bond from the port of first arrival, without appraisement or the payment of duty, to an interior port, where a consumption entry or warehouse entry may be made.

Documents required to be furnished the office of the Collector of Customs in making a formal entry of merchandise include the entry (Form 7501), declaration of ownership (Form 3347), bond for redelivery, production of missing documents, etc. (Form 7551), delivery permit (Form 7501a), a bill of lading and consular invoice. A form is now in quite general use, however, combining the entry, declaration, and redelivery bond.

The consular invoice is made out by the shipper on special forms furnished by the American consular officers, the shipper being required to certify to the truth of statements contained in the invoice before the consular officer at the place of manufacture or sale. Copies of this invoice are forwarded to the importer for use in making the customs entry.

When the entry is presented at the Customhouse, an entry clerk examines it to determine if it is complete and properly executed. He then checks up the calculations and makes an estimate of duties to be paid, which the importer deposits. The delivery permit, stamped to indicate that the duties have been paid, is then given the importer, which, on presentation on the pier, authorizes the inspector to deliver certain packages to the importer and certain other packages, indicated on the permit, to the Appraiser's Stores for examination and appraisement. An examiner at the Appraiser's Stores examines the merchandise and approves the entered values or advances them if he believes them to be too low. While the determination of the rate of duty to be paid is a function of the Collector, an advisory classification of the merchandise is made at the Appraiser's Stores. If no irregularities are discovered, the importer is notified to call for his packages. If irregularities are discovered in the examination of packages, the examiner may call on the importer for the redelivery of the balance of the importation, which has been removed from the pier on the delivery permit, which redelivery the importer is bound to make under the terms of his redelivery bond, so-called. After the work at the Appraiser's Stores has been completed, the papers are returned to the Collector, where the duties owing to the Government are computed. This is known as liquidation of the entry. If the liquidated duties are less than the estimated duties which have been deposited, the difference is refunded to the importer, and if the liquidated duties are higher, the importer is called on for an additional deposit.

If the importer is dissatisfied with the appraisement, he may, by appeal, secure a review by the Board of General Appraisers of the appraiser's decision (Sec. 501, Tariff Act 1922). Likewise, a review by the Board of General Appraisers and Court of Customs Appeals of decisions of the Collector may be obtained by the filing of a timely protest (Sec. 514, Tariff Act 1922).

Violations.—Automobiles and other vehicles arriving in the United States from Canada and Mexico are required to report without delay to the customs officer or customhouse nearest the place of such arrival. Failure to report subjects the offender to a fine of $100 (Sec. 459, Tariff Act 1922).

The Secretary of the Treasury is authorized to pay an award to any person other than a Government officer furnishing information to a customs officer regarding a violation or contemplated violation of the customs laws, which information leads to a recovery of duties, penalties or fines, the amount of such award to be 25 per cent. of the net amount recovered, but not to exceed $50,000 (Sec. 619, Tariff Act 1922). In the year 1925, $620,000 was recovered by the Government as a result of information furnished under this provision of law.

Summary.—Information in detail regarding customs procedure may be found in "Customs Regulations 1923," a 792-page document on sale by the Superintendent of Documents, Government Printing Office, Washington, D. C. The various phases of customs work are conveniently segregated in the thirty chapters of this publication.

In the year 1914, the port of New York collected 68 per cent. of the total customs receipts of the United States. This percentage in 1922 was 63 per cent.; in 1923, 57 per cent.; in 1924, 58 per cent; and in 1925, 55 per cent. As this indicates, the greatest increases in customs collections have been at ports other than New York.

Customs Transactions.—The following condensed table of customs transactions indicates the progress of the service:

	1921	1922	1923	1924	1925
Consumption entries:					
Free	217,053	182,267	209,778	206,154	209,319
Dutiable	261,094	310,722	389,511	416,449	428,989
Informal entries	110,758	120,231	145,151	164,102	182,505
Mail entries	409,286	508,590	560,498	638,773	742,917
Baggage declarations	287,108	234,470	284,644	339,541	340,685
Drawback entries	13,455	15,153	11,021	13,971	21,477

Assistant Secretary of the Treasury, Lincoln C. Andrews, is in charge of the Coast Guard, the Customs Service and the Prohibition Unit.

ACTIVITIES OF THE TARIFF COMMISSION

By Thomas O. Marvin

Chairman, U. S. Tariff Commission

Under the Tariff Act of 1922 the duties of the Tariff Commission were considerably increased. Sections 315, 316 and 317 of that Act gives the President power to change the rates of duty under certain conditions after the Tariff Commission has laid before him the facts in the case. Section 315 allows a change within an upward or lower limit of 50 per cent. of the prevailing duties if an investigation by the Tariff Commission discloses the fact that the differences in costs of production of similar competing articles in the United States and foreign countries warrant a change in the rate of duty. Section 316 authorizes additional duties or exclusion of imports by the President if unfair trade practices are found to prevail in the importation of the articles. Section 317 deals with trade discriminations practiced by foreign governments against the trade and commerce of the United States.

Cost of Production.—The principal activities of the Tariff Commission during the year 1925 have been in connection with investigations connected with Section 315. From September 1, 1922, to November, 1925, 326 applications have been received for action under this section of the law. The analysis of these applications is presented below by tariff schedules. (See page 556.)

In addition to the applications listed above, fourteen requests have been received for investigations looking toward the use of the American selling price ("American valuation") of similar domestic articles as the basis for levying duty upon the imported product. Eleven requests have

APPLICATIONS RECEIVED
September, 1922, to November, 1925
Under Section 315

Schedule	Number	Increase Requested	Decrease Requested
1. Chemicals, oils and paints	90	32	58
2. Earths, earthenware and glassware	26	16	10
3. Metals and manufactures of	28	16	12
4. Wood and manufactures of	14	7	7
5. Sugar, molasses and manufactures	7	..	7
7. Agricultural products and provisions	70	40	30
9. Cotton manufactures	9	7	2
10. Flax, hemp or jute and manufactures of	6	4	2
11. Wool and manufactures of	7	3	4
13. Paper and books	6	3	3
14. Sundries	38	18	20
Total	301	146	155

been received for adjustments of the duty upon certain products as compared with the duty upon other related products.

It is obvious that the appropriations of the Commission, and in some instances the merits of the matter will not justify a foreign and domestic cost investigation and a public hearing in every case in which a change in the duty is sought. The Commission in all cases makes a preliminary study, including usually a considerable amount of field work by the agents of the Commission in connection with each application, in order to determine whether or not an investigation is warranted. These preliminary activities supply the Commission with much valuable information of which ordinarily there is no public record. These data will, of course, be useful to the Commission and to Congress in connection with subsequent tariff legislation.

After a careful examination of the applications the Commission has ordered, from the beginning of 1923 to November, 1925, forty-nine investigations under Section 315. These investigations are divided among the schedules of the Tariff Act as follows:

INVESTIGATIONS ORDERED UNDER SECTION 315

Schedule	Number
1. Chemicals, oils and paints	16
2. Earths, earthenware and glassware	5
3. Metals and manufactures of	6
4. Wood and manufactures of	4
5. Sugar, molasses and manufactures	2
7. Agricultural products and provisions	6
9. Cotton manufactures	4
10. Flax, hemp or jute and manufactures of	1
13. Papers and books	1
14. Sundries	4
Total	49

Of the total number of investigations ordered under this section of the law seventeen were completed by November, 1925.

Changes Ordered.—The President, after receipt of a report of the Tariff Commission, supplemented in some cases by information from other governmental departments, has taken action, up to November 15, 1925, in respect to the following articles:

PROCLAMATIONS BY THE PRESIDENT

Commodity	Date	Action Taken
	1924	
Wheat	Mar. 7	Increase from 30¢ to 42¢ per bushel of 60 pounds.
Wheat flour, semolina, etc.	Mar. 7	Increase 78¢ to $1.04 per 100 lbs.
Bran, shorts and by-products	Mar. 7	Decrease of 7½% ad valorem.
Sodium nitrite	May 6	Increase 3¢ to 4½¢ per pound.
Barium dioxide	May 19	Increase from 4¢ to 6¢ per pound.
Barbital	Nov. 14	Increase to 25% based on American selling price.
Oxalic acid	Dec. 29	Increase from 4¢ to 6¢ per pound.
	1925	
Potassium chlorate	Apr. 11	Increase from 1½¢ to 2¼¢ per pound.
Sugar	June 15	No change.
Bob-white quail	Oct. 3	Decrease from 50¢ to 25¢ per pound.

The status of the more important investigations considered by the Commission during the year 1925 are briefly summarized in the ensuing paragraphs:

Butter.—The principal competing country exporting butter to the United States is Denmark. This butter is relatively high in quality and competes largely with the high-grade coöperative creamery butter produced in the states of Minnesota, Wisconsin, Iowa, Michigan and Illinois. Farm and creamery cost data were obtained in these states and in Denmark late in 1924. The data were summarized in the Statement of Information to interested parties, and a public hearing was held on April 21, 1925. All of the information is now being analyzed by the Commission in the preparation of a report to the President.

Swiss Cheese.—Farm and factory cost data have been received from the centers of the United States producing Swiss cheese, chiefly portions of Wisconsin and Ohio, and from Switzerland. The data were assembled in a Statement of Information to interested parties, and a public hearing was held in December, 1925.

Lace.—An extensive lace investigation is in progress, including the following types of lace: Nottingham lace curtains and nets, Levers, bobbinets, Barmen laces and Swiss embroidered curtains. In addition to field work in the domestic lace industries, cost data were obtained from the centers of production in France, Germany, Switzerland and England. The Statement of Information for interested parties was completed in this investigation, and a public hearing held in December, 1925.

China and Earthenware.—One of the most extensive investigations that the Commission has undertaken is that of china and earthenware. Portions of the domestic cost data were obtained in June, 1925, and foreign costs were obtained in Germany, Czechoslovakia, Holland and England. The foreign cost studies were completed in November, 1925, and the domestic field work will be completed early in 1926.

Halibut, Logs.—The Commission has recently held two public hearings for purposes of Section 315 upon important subjects affecting the Pacific coast, namely, halibut and logs (of fir, spruce, cedar or western hemlock).

The halibut industry in the Pacific Northwest has assumed large proportions in recent years. About 90 per cent. of the halibut catch of the United States is made by American vessels on the Pacific coast, and a large percentage of the Canadian catch is on that coast. Many of the American vessels, however, transfer their catch to the rail head in Canadian ports and ship the halibut in bond free of duty from Canada to the United States.

The Commission obtained cost data for a large portion of the catch in Canada and the United States on both the Pacific and Atlantic coasts, and a public hearing was held in Seattle on August 10, 1925, at which were discussed the many questions involved in the investigation. The report in this investigation has been submitted to the President, and the subject had been taken up by the government of Canada and the government of the United States. The negotiations on the part of the United States have been conducted by the Department of State.

The log investigation was of special interest to the Pacific Northwest also, and after the cost data had been obtained in this area, a hearing was held at Seattle on August 10, 1925, and the report to the President is in course of preparation.

Other investigations which received the active consideration of the Commission during 1925 are as follows: Plate Glass, Pig Iron, Cotton Hosiery, Linseed Oil, Print Rollers, Taximeters, Maple Syrup, Gold Leaf, Men's Sewed Straw Hats, Bentwood Chairs, Rag Rugs, Granite, Glue, Edible Gelatin, Sodium Silicofluoride and Methanol.

Methanol, or wood alcohol, presents a somewhat peculiar case in that the imports are of the newly discovered synthetic methanol, made in Germany from coal tar products, and imported in competition with the long-established domestic industry producing methanol by the distillation of hard woods.

Unfair Trade Practices.—Investigations for purposes of Section 316 (unfair trade practices in the importation of merchandise), and Section 317 (discrimination against the commerce of the United States) have not been so numerous nor so wide in scope as the investigations under Section 315 previously mentioned.

From September, 1922, down to the end of 1925, fourteen applications for consideration under Section 316 have been received, and three investigations were made, and hearings held. In five other instances preliminary examinations have been made which resulted in no further action by the Commission.

Discriminations. — Under Section 317 nine reports dealing with alleged discrimination in twenty-five countries and colonies have been submitted to the President.

Surveys and Reports.—Another major division of the Commission's activities relates to the preparation of surveys and reports, under the general powers of the Commission, upon tariff problems and the operation and effects of the tariff law.

One of the most extensive general reports of the Commission considered in 1925 was the cost of production of sugar beets. This study is based upon detailed farm costs for 2,242 farms in the states of Michigan, Nebraska, Colorado, Montana, Utah, California, Wyoming and Ohio. Not only was cost data included in the report, but an economic survey of the industry has been made. Another extensive report published in 1925 is that concerning the broad silk industry. Much domestic cost-data is included in this report, and a complete survey of the conditions in the industry is made.

The annual Census of Dyes and Coal Tar Products is regularly made by the Commission, and the report for the calendar year 1924 was issued in October, 1925. In addition to production and import statistics a general statement of the prevailing conditions in the dye industry is furnished.

Other surveys and general reports prepared by the Commission in 1925 are as follows: Artificial Silk, Tops and Yarns of Wool, Vegetable Fibers other than Cotton, Worsted Fabrics of Wool, and the Cattle and Beef Industry, with special reference to the trade between Canada and the United States.

Foreign Office.—Another important activity of the Commission is the work of its foreign office. Three research men are permanently stationed abroad, including the chief of the foreign office, with headquarters at Brussels. The more important activities carried on by the foreign agents independently or in coöperation with other experts from the Commission have been in connection with the following subjects: a survey of the artificial silk industry in seven of the countries of Europe; a survey of the tan calk leather industry in eight of the countries of Europe, and studies in the cost of production of eight commodities which were the subjects of investigation by the Commission for purposes of Section 315.

MAGNITUDE AND PROGRESS OF MANUFACTURING

By Howard L. Clark

Statistical Editor, Manufacturers' Record

Value of Manufactures.—Manufacturing industries of the United States are turning out products with an annual wholesale value of over sixty billion dollars. In other words, all of the factories in this country produce commodities valued in excess of one billion dollars every week in the year. So great has been our manufacturing growth that the product of these industries to-day is about six times the annual farm value of all crops raised on all the farms of the country and over three and one half times the annual aggregate farm value of all agricultural products, which includes crops, animals and livestock products. This comparison keeps in sight the fact that the United States is one of the great agricultural countries of the world; and while we consume most of the things we produce, last year over $1,588,000,000 of finished manufactured goods were exported, more than $610,000,000 of semi-manufactures, over $537,000,000 of manufactured foodstuffs and over $392,000,000 worth of crude foodstuffs. The total value of the country's domestic exports last year amounted to $4,497,649,000, more than 35 per cent. of which represented finished manufactures.

Perhaps the magnitude of the manufacturing interests of the United States can better be grasped when we learn that though this country embraces less than 6 per cent. of the world's area, and about 6 per cent. of the world's population, we are supplying a very large proportion of the major industrial needs of the world, such as iron, coal, oil, lumber and cotton.

Our iron furnaces are contributing 60 per cent. of the world's pig iron; our smelters produce nearly 53 per cent. of the world's copper; our saw mills produce about 46 per cent. of the world's lumber; we produce 59 per cent. of the world's steel ingots and castings; 57 per cent. of the world's paper and about 85 per cent. of the world's automobiles, to name only a few manufactured commodities of importance.

In 1919, the latest figures available, the amount of capital invested in manufactures in the United States was over forty-four and a half billion dollars, compared with seventy-eight billions invested in agriculture.

Productive Establishments.—Complete statistics are not available for the manufactures of the country later than those of the census of 1923. These figures embrace all establishments having an annual production value of $5,000 and over. In that year more than 196,000 establishments (the word "establishment" meaning one or more plants owned or controlled by one management), were operating throughout the country. These establishments, in 1923, produced $60,555,000,000 worth of manufactured goods; and the record of industrial activity for the past year clearly indicates that the United States is exceeding all former production figures. Industry as a whole was greatly enlarged to handle the demand created by the war and Europe's needs, some branches having doubled their capacity since 1914. It is true that many of the basic manufactures have not been operating to this enlarged capacity, but they have been running from 80 to 85 per cent. of it much of the time in the last months, and thus have brought about an even greater increase in manufactures to-day than the 1923 census indicates.

New England, long dominant in manufacturing, has been surpassed by the great manufacturing development of New York and Pennsylvania, and the more recent expansion of the Middle Western States, but New England and the Middle Atlantic States produce over 43 per cent. of the nation's manufactured product. New England has continued to expand and perfect its manufacturing, but in the last decade the supremacy of the Northeast as the leading manufacturing section of the country has been challenged by the great growth of manufactures in the Middle West, and in the last two or three years by the devolpment of industry in the Southern States.

Automobiles.—The outstanding feature of the manufacturing progress of the East North Central States is found in the remarkable growth of the automobile industry centered there. Last year this one industry produced 3,243,285 passenger automobiles and 374,317 motor trucks, with a combined wholesale value of over $2,326,000,000. The aggregate wholesale value of motor vehicles and parts amounted to over $3,168,000,000, giving it a position of first rank among the country's manufactures. The amount of capital invested in the motor vehicle manufacturing business in the United States in 1924 was over $1,691,000,000.

Cotton Goods.—The rapid increase in cotton manufacturing in the South is a feature of the industrial development of that section. It is estimated that one billion dollars are invested in Southern cotton mills, and the South now contains over half of the cotton mills, and employs over half of the people engaged in cotton goods manufacture in the United States. These Southern mills produce 52 per cent. of the total value of our cotton goods output, which amounted to $1,901,000,000 for the whole country in 1923; and Southern mills are consuming 68 per cent. of the American cotton used in all American mills.

Radio Equipment.—Another industry which has had a phenomenal growth in the last two or three years is the manufacture of radio equipment and supplies, surpassing the record set by the automobile industry in its rapid advancement. It is estimated that more than one billion dollars are invested in the radio business to-day. About twenty-five hundred radio manufacturers, three hundred Government radio stations and about six hundred private broadcasting stations, variously estimated as reaching from twenty to thirty million American citizens through their daily programs, show the magnitude of this industry as illustrating to what extent specialty manufacturing lines, have developed in recent years along with the major basic industrial growth of the country.

So great has been the manufacturing development of the United States that it is difficult for us to comprehend this stupendous growth and, as this country far out-ranks any other country in the world in this respect, this expansion must indeed be amazing to people in other lands.

Capital and Output.—Fifty years ago the United States produced about $5,000,000,000 worth of manufactured goods. By 1890 this had nearly doubled and we were beginning to be considered a real manufacturing country. Since 1900 the amount of money invested in the manufacturing enterprises of the United States increased from $8,975,000,000 to over forty-five billion, or more than 400 per cent., while the value of the manufactured products of these industries increased during the same period from $11,407,000,000 to more than sixty billion, or 430 per cent. The gain in manufacturing has been steady both in capital invested and in the value of finished products for each census period between 1869 and 1914, with a decided jump following the war inflation of 1919, and a pronounced decline during the post-war depression of 1921, followed by another period of activity culminating in the record figures of to-day which are even surpassing the feverish manufacturing activities of the war

Summary of Manufactures, 1923

COMPARED WITH 1921, 1919 AND 1914

(Compiled from United States Census Reports)

	1923 *	1921 *	1919 †	1914 †
Number of establishments..	196,309	196,267	290,105	275,791

Salaries paid	$2,805,450,000	$2,563,103,000	$2,880,868,000	$1,274,438,000
Wage earners (average number)	8,778,950	6,946,570	9,096,372	7,036,247
Wages paid	$11,009,298,000	$8,200,324,000	$10,533,400,000	$4,078,332,000
Value of products.........	$60,555,998,000	$43,653,283,000	$62,418,079,000	$24,246,435,000
Cost of materials.........	$34,705,698,000	$25,336,617,000	$37,376,380,000	$14,368,089,000
Value added by manufacture	$25,850,300,000	$18,316,666,000	$25,031,698,000	$ 9,878,346,000
Primary horsepower	33,094,228	‡	29,410,192	22,307,189

* Excluding all factories producing less than $5,000 annually and automobile repairing which were included in 1919 and 1914.

† Includes all factories producing annually products valued at $500 and over and plants engaged primarily in automobile repairing.

‡ Data not collected, 1921 census.

period in the value of output, and what is more important the goods our plants and workers are turning out now, instead of being materials of destruction when billions of dollars of manufactured products went directly to the service of war, are utilized for the benefit of mankind and the upbuilding of the United States and the world.

Despite the slight decrease in the aggregate value of manufactured products between 1919 and 1923, the annual output of industries, measured in quantities—not values—showed a considerable increase, which has been estimated at 19 per cent. by the Department of Commerce, and, as previously stated, the percentage is greater now than it was in 1923.

On page 560 is given a statistical summary of all manufactures combined in the United States for 1923, with a comparison of the three preceding census years, 1921 immediately following the world war, 1919 during the height of war-created activity and prosperity, and 1914 the first pre-war year.

Bases of Statistics.—Attention is called to the fact that the 1923 and 1921 census figures relate to manufacturing establishments whose output during the year was valued at $5,000 or more, and are not exactly comparable to those of 1919 and 1914. However, the elimination of data for the smaller establishments reported in 1919 and 1914 has only a slight effect on the totals except for the item of number of establishments.

Manufacturing establishments in 1923 numbered 196,309, compared with 196,267 in 1921, 214,383 in 1919 and 177,110 in 1914. The figures for 1919 and 1914 have been adjusted to exclude all factories reporting products having an annual value of less than $5,000 and also the output of automobile repairing establishments, which were not reported in 1921 and 1923. The small increase in the number of establishments reporting in 1923 compared with 1921 and the decrease since 1919 were due in part to consolidations and readjustment after the war following the deflation of 1920 and 1921.

The total number of persons engaged in manufacturing in the United States about equals the number engaged in agriculture and we employ over one million more wage earners in our factories than the total population of industrial Belgium. The average number of wage earners employed in 1923 was 8,778,950, an increase of 26 per cent. compared with 6,946,570 employed in 1921, and the adjusted figures of 9,000,059 in 1919 and 6,896,190 in 1914.

Census reports call attention to the fact that:

> A very much better measure of the actual value created by manufacturing processes is the "value added by manufacture," namely, the difference between the cost of materials (including fuel, mill supplies, containers, etc.) and the factory value of the finished products. This aggregated $25,850,000,000 in 1923, an increase of 41 per cent., as compared with $18,316,000,000 in 1921 and of a little over 4 per cent. as against $25,031,000,000 in 1919. Thus, despite a slight decrease in aggregate value of products between 1919 and 1923, together with an increase in expenditures for wages, the value added by manufacture increased somewhat, this increase being due to a decline in the cost of materials from $37,376,000,000 in 1919 to $34,705,000,000 in 1923. The latter figure represents a decrease of 7 per cent. as compared with 1919, but exceeds by 36 per cent. the corresponding total for 1921, which was $25,336,000,000.

The rated horsepower capacity of engines, water-wheels, electric motors, etc., used for primary power in manufacturing establishments, aggregated 33,094,000 in 1923, an increase of 12 per cent. as compared with 29,410,000 horsepower in 1919, and a gain of nearly 50 per cent. compared with the 22,307,000 horsepower operated during the pre-war year 1914.

Principal Products.—It is significant that among the ten leading industrial groups in value of output that food, clothing, and iron and steel manufactures lead. Topping the list are manufactured food and kindred products for which is reported an annual wholesale value of $9,520,000,000 in 1923. Textiles and their products rank second with an output of $9,487,000,000. Iron and steel and their products, excluding machinery, are in third place with a production of $6,828,000,000 for the year. In these ten industrial groups are found the basic manufactures of the country and the magnitude of their operations explains the solid foundation upon which industrial America rests and its position among the manufacturing nations of the world. The annual output of many of these groups shows a small decline in value compared with the boom period of 1919. With the exception of lumber and allied industries each of the ten groups discussed made a gain in primary horsepower utilized in 1923 compared with 1919. Excepting in the number of establishments, all the groups increased in every item reported compared with the 1921 figures. The amount paid to wage earners during 1923 increased for each of the industrial groups reporting in 1921 and made a gain, compared with 1919, for all groups excepting the chemical and allied-products group and the transportation equipment, air, land and water group. At the bottom of this page appears a compilation of the ten principal manufacturing groups in order of value of output for 1923 compared with former years.

ANALYZED SUMMARY OF MANUFACTURES OF TEN LEADING GROUPS OF INDUSTRIES IN VALUE OF PRODUCTS

(COMPILED FROM UNITED STATES CENSUS REPORTS)

Industry	Year	Number of Establishments	Wage Earners (average number)	Wages Paid	Primary Horsepower	Value of Products
Food and kindred products	1923	51,931	682,318	$ 795,583,000	3,708,438	$ 9,529,773,000
	1921	51,582	608,067	714,901,000	......	8,145,082,000
	1919	69,423	733,664	774,722,000	3,203,106	12,748,348,000
	1914	67,403	536,436	303,345,000	2,503,932	4,977,760,000
Textiles and their products	1923	26,797	1,719,438	1,748,069,000	3,801,701	9,487,184,000
	1921	25,985	1,510,867	1,473,219,000	......	6,963,886,000
	1919	28,473	1,612,060	1,482,879,000	3,254,033	9,226,646,000

	1914	6,758	307,060	169,358,000	311,194	1,104,595,000

Summary of Billion Dollar Establishments.—Sixteen individual manufacturing industries produce annually more than a billion dollars each per year. Four of these industries produce annually goods valued at more than two billion dollars. Motor vehicle manufacturing heads the list with an annual output valued at over $3,160,000,000, and iron and steel works and rolling mills are a close second, with a production value of $3,154,000,000. The table on page 564 gives a summary of the billion dollar industrial group in the order of their importance as to annual value of output.

Economies.—In reviewing business conditions of last year Secretary Hoover stated that the manufacturing census taken for the year 1923

> "brings out vividly the rapid progress in industrial efficiency and in elimination of economic waste during recent years. The figures for 1923 when reduced to a quantitative basis (in order to avoid the effect of decreased purchasing power of the dollar) show that our manufacturing output is increased by fully 60 per cent. over that of 1914. It also shows a gain over 1919. Against this large increase in products the number of wage-earners increased by about 25 per cent. as between 1914 and 1923, and it is interesting to note that the horsepower used increased 50 per cent. in the same period. Wages for 1923 and 1924 were generally maintained at about 100 per cent. higher than in 1913, and with the cost of living on a basis of about 70 per cent. over the pre-war level our labor is receiving a large share of the result of this increased efficiency in the highest real wages of our history. The higher real wage has been expressed both in advancing standards of living and in greater savings on the part of the masses of the population."

Sections Compared.—In a study of the industrial development of the country by geographical divisions and states it will be found that the South as a whole (Missouri in this estimate is classed as a Southern state) fared better than any other section of the country, except the Pacific Coast, in the increase in the number of manufacturing establishments. This was achieved in spite of many consolidations of plants in textile centers to bring them under one ownership; they therefore count as one establishment instead of several as formerly listed. The South increased its establishments in 1923 over 1921 by 1.5 per cent. There was an increase of 0.1 per cent. in New England, a decrease of 1.7 per cent in the Middle Atlantic states, an increase of 1 per cent. in the East North-Central states, a decrease of 4.3 per cent. in the West North-Central states, and an increase of 6.2 per cent. for the Pacific Coast.

The value of New England's manufactured products in 1923 was $6,420,000,000, or an increase of 30 per cent. compared with 1921; while the value of the manufactured products of the Middle Atlantic states in 1923 was $19,739,000,000, an increase of 35 per cent. The value of the manufactured products of the East North-Central states was $17,821,000,000, or an increase of 50 per cent. over 1921. The West North-Central states increased the value of manufactured goods from $3,506,000,000 in 1921 to $4,299,000,000 in 1923. In the South Atlantic group of states the value of manufactures in 1923 was $4,238,000,000 compared with $2,985,000,000 in 1921.

Banner States.—New York and Pennsylvania are the leading industrial states of the country. In 1923 the state of New York reported 38,186 manufacturing establishments with an output valued at $8,961,000,000 and Pennsylvania had 19,054 establishments with an annual production of $7,382,000,000. The four states of New York, Pennsylvania, Ohio and Illinois in 1923 produced an aggregate value of manufactures of $26,530,000,000, which is nearly 44 per cent. of the country's total, and $2,284,000,000 more than the total value of all manufactures produced in the United States during the pre-war year 1914. Massachusetts was the only New England state to report an increase in the number of establishments in 1923. New York had a very slight increase in establishments while Pennsylvania reported a loss of 6 per cent. in the number of establishments; but the value of New York's manufactures in 1923 increased only 28 per cent. against a 45 per cent. gain in Pennsylvania. Ohio, Illinois, Michigan and New Jersey followed in order New York and Pennsylvania in the value of manufactured products. Massachusetts is sixth in manufactured output.

ANNUAL PRODUCTION VALUES OF OVER ONE BILLION DOLLARS (1914-1923)

(Compiled from United States Census Reports)

Industry	Year	Number of Establishments	Wage Earners (average number)	Wages Paid	Primary Horsepower	Value of Products
Motor vehicles	1923	351	241,356	$406,730,000	435,545	$3,163,328,000

DIVISION XXI

TRANSPORTATION AND COMMUNICATION

IMPORTS AND EXPORTS

By Frank D. Graham
Professor at Princeton University

General Considerations. The external commerce of the United States is in process of adjustment to a series of important changes. The war established our position as a lending nation not only during and immediately after the conflict but for many years to come. The United States is at present the chief capital market of the world and the great loans contracted a few years ago between our government and the governments of the Allied Powers are now being followed by large private investments in foreign securities. These loans must have profound repercussions on our foreign trade, affecting not only its volume and the relation between exports and imports, but also in differing degrees the constituent elements of both of these. The year to year developments in foreign trade are therefore at this time of more than ordinary interest.

Nineteen twenty-five was the first year of the operation of the Dawes Plan for reparation payments by Germany but the sums transferred were not of sufficient magnitude to cause any considerable disturbance in international trade. The trend of the trade currents which these payments will eventually establish is therefore not yet obvious. None the less the confidence inspired by the acceptance of the Plan was a big factor in the investment of American capital abroad and, as a consequence, in our foreign trade. Reference will presently be made to the effect of these loans.

For the first time since the war, foreign trade seems in the past year to have attained what is at least a temporary equilibrium. Ever since the autumn of 1920 gold had been coming into the United States in large quantities. During this time a total of well over a billion dollars moved toward our shores, while the historic function of gold movements in effecting international price adjustments was lost in the spasmodic play of exchange rates. Beginning with the last month of 1924, however, and continuing through the first six months of 1925 exports of gold were in excess of imports and though another reversal occurred in July, there is little evidence that this is likely to continue for any great length of time or involve any very large values. Trade is apparently once more on a fairly even keel, total debits and credits are in approximate balance, and there is a consequent cessation of large transfers of gold.

Total Foreign Trade.—The official figures for the fiscal year ending June 30, 1925, show a total United States foreign trade of $8,688,838,000 as against $7,865,693,000 in 1924 and $7,737,692,000 in 1923. Of the 1925 total, $4,864,667,000 was in exports (including exports of foreign goods) and $3,824,171,000 in imports. Both exports and imports showed increases over the preceding years, but exports grew at the more rapid rate, so that the excess of exports is $1,040,496,000 as compared with $757,619,000 in 1924 and only $175,774,000 in 1923. For several years it has been the expectation of most authorities on international trade that merchandise exports and imports would develop something like a balance, and the growing excess of exports since 1923, amounting last year to more than a billion dollars, comes as a distinct surprise.

Causes of the Rising Excess of Exports.—The causes of this excess of exports are various, but the most important is undoubtedly the unexpectedly large issues of foreign securities which have been taken up in our investment markets. The Farmers' Loan and Trust Company of New York estimates these new capital flotations at $1,007,000,000 in 1924 as against $304,000,000 in 1923, and the pace has been somewhat accelerated in the year just past. Minor factors in the excess of exports are the increase in American tourist travel in Europe and the relative failure in 1924, except in the United States, of those crops which we largely export. The broad tendency since 1921 seems to be toward a gradual increase in both our imports and exports, the former in a steady movement, the latter jerkily, in correspondence with the fluctuating volume of foreign loans taken up in this country. It is probable that in the future such loans of this sort as are consummated will be spread somewhat more evenly. We can then look forward to a stable growth in international trade with a tendency toward an increasing ratio of imports to exports as the interest payments on new borrowings mount up and payments on our war loans are inaugurated by those nations with which we have not yet concluded a refunding agreement.

Exports and Imports by Great Groups.—The exports (domestic) and imports by great groups in the fiscal years ending June 30, 1924, and 1925 were as follows:

DOMESTIC EXPORTS

(In millions of dollars)

Class	1923	1924	1925	Per Cent. of Total		
				1923	1924	1925
Crude materials	1,017	1,302	1,393	26.2	30.8	29.2
Crude foodstuffs and food animals	394	203	483	10.1	4.8	10.1
Manufactured foodstuffs	584	561	577	15.0	13.3	12.1
Semi-manufactures	486	595	646	12.5	14.1	13.5
Finished manufactures	1,396	1,554	1,670	36.0	36.8	34.9
Miscellaneous	6	5	7	.2	.2	.2

IMPORTS

(In millions of dollars)

Class	1923	1924	1925	Per Cent. of Total		
				1923	1924	1925
Crude materials	1,475	1,200	1,430	39.0	33.8	37.4
Crude foodstuffs and food animals	352	385	451	9.3	10.8	11.8
Manufactured foodstuffs	506	530	451	13.4	14.9	11.8
Semi-manufactures	711	658	701	18.9	18.5	18.3
Finished manufactures	716	756	767	19.0	21.3	20.1
Miscellaneous	17	23	22	.4	.7	.6

These figures must be read in the light of special causes peculiar to one year and not operative in another. Thus the exports of crude foodstuffs varies very greatly with the respective crops in any given year in Europe and America. The high figures in this group of exports in 1925 are due almost entirely to the wheat movement. In this single commodity the exports of 1925 were in excess of those of 1924 by $220,000,000, the total excess in this group being only $280,000,000. The increase in this group of exports is almost certain to prove ephemeral. Allowing, then, for special factors of this sort the most striking aspect of the table given above is the steady growth in the exports of finished manufactures. This movement has been in progress for a number of years and there is no evidence of any slackening in its rate. It reflects our increasing industrialization and indicates that the decreasing rates of exports to imports which the future probably holds will be at the relative expense of our non-manufactured exports.

Ratio of American to World Foreign Trade.—According to estimates of the National Foreign Trade Council, the total world foreign trade in 1925 approached, in real as against pecuniary values, to within 5 per cent. of the 1913 volume, but the distribution among the various nations of the world is in proportions very different to that of the pre-war period. There is no reason to suppose that there will be any tendency toward the 1913 ratio of distribution. On the other hand, the norm has doubtless been completely altered by the changes which the war brought about. Our present ratio of exports to world exports is 21.7 as against 15.7 in 1913 (1913 values taken as a base). It would, however, be erroneous to suppose that an increasing or decreasing proportion of the world's foreign trade bears any necessary relation to prosperity. Other countries showing increases in the ratio include France, Italy and China which are scarcely more prosperous as compared with the 1913 situation than Holland (including the Dutch East Indies) and Brazil, both of which show declining ratios. Changes in the volume of foreign trade are, in general, a very poor index of prosperity.

Monopolies in Foreign Trade.—A disquieting development of the year was the increase in control, exerted in one way and another over those commodities which are produced altogether or in large part within the confines of a single political unit. The most striking case was that of crude rubber. Whether as a result of such control or not,—and certainly the control was a factor,—the price of rubber rose to an extraordinary degree during the year. The temporary success of such manipulation is likely to encourage further attempts of the same sort and to provoke international trade wars which can scarcely enure to the advantage of any nation and certainly not to that of the world at large. Some sort of international agreement or control would seem to be the only feasible solution of the difficulty.

CONDITIONS OF INTERNAL COMMERCE

By Frank D. Graham
Professor at Princeton University

Readjustment of Prices.—The volume of commerce depends on three factors: (1) the volume of production, (2) the range of specialization, both individual and regional, and (3) speculation. Only such trade as arises from the first two of these factors contributes appreciably to general prosperity, and production, specialization and trade mutually give rise each to the others. There can be little doubt, for instance, that the high level of productive activity which marked the year 1925 was in part due to the readjustment which took place in the relative prices of agricultural and manufactured commodities facilitating commerce by increasing the purchasing power of the farming population and thus making it possible to utilize more fully existing manufacturing equipment. This is perhaps the most important improvement of the year in the conditions of internal commerce, prices of the two types of commodities having been far out of line ever since the general slump in prices in 1920.

Transportation.—To commerce and productive specialization transportation is vital. There is general agreement that there was a great improvement during the year in the speed with which freight shipments were handled. A symposium by prominent business and railroad men in *Nation's Business* for October, 1925, alleges remarkable gains in this respect. "Hand-to-mouth" buying is becoming the rule, and though such buying has been much maligned, there can be no doubt that the condition which makes it possible is a real social gain by reason of the saving in interest on the investment during transit, the more intensive use of railroad equipment, and the reduction in the amount of capital necessarily devoted to carrying stock in trade.

In addition to this improvement in rail transportation, motor transport has continued to increase in volume and to provide opportunities for a type of commerce which has hitherto been impossible. Such transport is most desirable in districts where there are no rail facilities but it is also extremely useful and is more and more fully employed in the local distribution of commodities, in supplementing existing rail and water service and in long haul transportation of special commodities, particularly those in which the cost of crating is high and can be dispensed with when motor trucks rather than the railroad are used for transportation. (See article on Commodity Transportation by Motor Truck on Public Roads, U. S. Dept. of Agriculture, Vol. 6, No. 6.)

During the year improved highways were pushed forward at an accelerated rate to the great benefit of commerce. The Federal government rendered financial aid in the construction of nearly 9,000 miles of road in the twelve months ending June 30, 1925, as against a total of 32,500 miles from 1917-1924. Meanwhile, in part no doubt consequent thereon, motor truck registrations were growing at an increasing rate. This rate of growth now amounts to about 20 per cent. a year.

Merchandising Methods.—Outside the field of transportation the most significant development in the conditions of commerce in 1925 was probably the augmentation of the business done by merchandising chains relative to the growth of commerce in general.' With the exception of cigar and music chains, this type of merchandising secured a proportionately larger share of the trade in practically every line in which it is a factor. This is undoubtedly due to the real economies which merchandising of this type offers and augurs for the near future the entry of chain store organizations into fields where they do not now operate.

Simplified Practice.—The agitation of the Bureau of Standards of the Department of Commerce for simplified practice and the elimination of unnecessary varieties in standard commodities has borne fruit in the lowered cost of manufacture and sale of these goods. Conferences of appointees of the leading producers in a considerable number of industries have been able to reach agreements leading to the elimination of much futile variety in bricks, bolts, bars (steel) and many other products, though much yet remains to be done.

Little progress was made in the handling of freight in congested centers. Problems of freight movement in and around terminal points are still largely waiting for solution. The economies which would attend railroad consolidation were realized to but a small degree. There seems to be little prospect of the railroads voluntarily undertaking the consolidations urged upon them and their struggle for competitive advantage, whatever its virtues, leads slowly, if at all, to desirable terminal arrangements.

Monetary and banking conditions on which commerce is so highly dependent were favorable in 1925. Credit was readily available for any sound project and the stability of general prices was substantially preserved. The danger of inflation was reduced by the cessation from January to July of the continuous stream of gold imports which had been flowing since 1920, and though imports were resumed in the later months of the year, they were not in sufficient volume seriously to affect the preexisting situation.

XXI. TRANSPORTATION AND COMMUNICATION

HIGHWAYS AND MOTOR ROADS

By Thomas H. MacDonald

Chief of Bureau of Public Roads, Department of Agriculture

CONSTRUCTION

Mileage of Roads.—The total mileage of highways in the United States on January 1, 1925, according to statistics compiled by the Bureau of Public Roads from reports received from the several State highway departments, was 3,002,916 miles, of which 259,721 miles are included in the systems of State highways designated for improvement under the supervision of the State highway departments. The balance of 2,743,195 miles consists of rural roads of local importance mainly, supervision over which is vested in the county and township authorities.

Mileage Improved.—On the same date 128,347 miles of the State highways were improved with some form of surfacing; 35,279 miles were graded and drained as the first stage of an improvement which will be completed by surfacing as traffic demands and funds for the purpose become available. The balance of 96,095 miles of the State highway systems was partially graded and generally unimproved earth road.

The rural roads under the supervision of the local authorities, at the beginning of the year 1925 included 339,559 miles of surfaced roads, 201,015 miles of unsurfaced earth roads improved by grading and draining in accordance with engineering standards, and 2,202,621 miles of unimproved earth roads.

The character of the improvement of the roads of the two classes at the beginning of the year is indicated by the following table which gives the mileage of the several types of surfacing.

Type of Surfacing	State Highways	Local Roads	Total
	Miles	Miles	Miles
Sand-clay	10,043.5	53,638.4	63,681.9
Gravel	58,357.1	185,925.0	244,282.1
Waterbound macadam	5,344.1	54,890.6	60,234.7
Surface-treated macadam and gravel	13,891.6	12,789.1	26,680.7
Bituminous macadam	9,686.5	7,852.6	17,539.1
Bituminous concrete	4,453.0	2,990.5	7,443.5
Sheet asphalt	771.4	1,488.6	2,260.0
Portland cement concrete	22,783.6	8,362.8	31,146.4
Brick	2,882.0	1,437.4	4,319.4
Wood, asphalt and stone block	134.5	187.2	321.7
Miscellaneous	......	9,996.3	9,996.3
Total	128,347.3	339,558.5	467,905.8

Annual Gain.—During 1924, a total of 31,541 miles were surfaced by all States and counties, of which 17,207 miles were on the State highway systems. The mileage built to established grade and drained by the States and counties was 13,689 miles; by the State highway departments alone the mileage so improved was 5,957 miles. The total mileage improved to some degree during the year was 45,230 miles. This mileage includes that improved under the immediate supervision of the State highway departments with Federal aid.

Records of the mileage improved during 1925 are not yet available; but judging from the mileage of Federal-aid roads constructed during the fiscal year ending June 30, 1925, the accomplishment of 1925 has been at least as great and probably greater than that of the preceding year. The 11,329 miles of Federal-aid roads completed during the last fiscal year established a new record for the cooperating Federal and State Governments, exceeding by more than a thousand miles the largest previous year's performance, that of 1922.

The Federal-aid road construction work of the fiscal year 1925 brings the total mileage completed since the passage of the first Federal-aid road act in 1916 up to 46,486 miles; and, in addition to the mileage completed, a great deal of work had been done on the 12,463 miles which at the close of the fiscal year were under construction. This is indicated by the fact that 3,248 miles were completed between the end of the fiscal year on June 30 and November 1. With the addition of this mileage recently completed the result of the coöperative work to November 1 is the completion of nearly 50,000 miles of highway.

FEDERAL AND STATE AID

The Federal-aid Highway System.—The Federal-aid highway system designated by the several State highway departments and approved by the Secretary of Agriculture in accordance with the Federal highway act of 1921 includes at present 178,797 miles. The limiting mileage prescribed by the law and ultimately to be included in the system is 7 per cent. of the total mileage of highways on record in the United States at the time of the passage of the law. This limiting mileage is 200,349 miles.

On October 31, as indicated above, 49,734 miles of this system had been constructed either as some form of surfaced highway or as graded and drained roadbeds preparatory to further improvement. On the same date 12,187 miles were under construction with Federal aid and 2,230 miles had been approved for construction by the Secretary of Agriculture. Practically all of this mileage is on the Federal-aid system, there being only a small mileage constructed prior to 1921 which is not included. Up to this date, therefore, a mileage equivalent to approximately one-third of the limiting mileage of the system had already been constructed or undertaken for improvement.

State Highway Departments Without Federal Aid.—In this category had been constructed or undertaken up to January 1, 1925, approximately 65,000 miles, which added to the mileage improved with Federal assistance indicates that the initial improvement of the system is approximately two-thirds completed. It must be borne in mind, however, that the improvement to date includes a considerable mileage of roads which have been only graded and drained and an additional mileage improved with low types of surfaces such as sand-clay and gravel. It will be necessary to add to these roads as traffic increases surfaces adequate to withstand the loads which ultimately will be carried by these roads—the most important in the country. It will also be necessary, as funds become available, to eliminate grade crossings and replace existing temporary bridges with structures of durable design. Because of the pressing demand for extension of improved mileage this necessary work is, in some cases, being held in abeyance.

FINANCE

Revenues and Expenditures.—Reports of revenues collected and expenditures made for highways by the States and counties during 1925 are not yet available. In 1924, the total State revenues were $555,397,045, of which $38,367,202 accrued from the taxation of property, $101,653,327 from bond issues, $174,816,973 from motor vehicle license fees, $47,810,615 from gasoline taxes, $91,400,832 from the Federal Government in the form of Federal aid for road construction completed, $87,998,486 by transfer from the counties, and $13,349,610 from miscellaneous receipts. In addition, the States had on hand at the beginning of the year a balance of funds from the previous year amounting to $156,826,702, so that the total of funds available to the State highway departments during the year was $712,223,747.

The estimated total revenues of the counties during the same year were $626,404,155, bringing the total revenues up to the estimated amount of $1,338,627,902.

The estimated total expenditure by the States, counties and Federal Government during the year was $1,180,005,000. Of this amount approximately $600,541,000 was expended by the State highway departments exclusive of the $91,400,832 expended by them for which they were reimbursed by the Federal Government; and approximately $579,464,000 was expended by the counties and other local governments. All these revenues and expenditures are exclusive of the revenues and expenditures of municipalities for city streets.

Federal Expenditure.—During the fiscal year 1925 (terminating June 30, 1925) the Federal Government expended $95,749,998. This was probably somewhat less than one-tenth of the total highway expenditure of the nation during the same period. The total Federal payments for the 49,734 miles of Federal-aid roads completed up to October 31, 1925, were approximately $402,206,000. The total cost of these highways was approximately $910,536,000, the difference between this and the Federal payments being the contribution of the States.

The Federal funds authorized by Congress for expenditure during the fiscal year 1926 (ending June 30, 1926) and apportioned to the States are $73,125,000. The total of funds appropriated, or authorized and to be appropriated as needed, since the establishment of the Federal-aid policy in 1916, is $598,250,000. Of this amount, as indicated above, approximately $402,206,000 have been expended upon the roads which have been entirely completed; approximately $124,122,000 are definitely allotted to the roads which are under construction; and $18,206,000 are allotted to the projects which have been approved for construction; leaving a balance of approximately $53,716,000 unobligated on October 31, 1925. This amount will be drawn upon for allotment to projects during the balance of the fiscal year.

DESIGNATION OF UNITED STATES ROUTES

Connected System.—Important for the year 1925 is the designation of a connected system of 75,884 miles of main interstate roads as United States routes which will be numbered in all States as continuous routes and uniformly marked with standardized direction and warning signs for the better guidance of interstate travelers. With more than 18,000,000 motor vehicles now registered the volume of interstate travel has already reached large proportions, and it is rapidly increasing.

Recognizing this condition the American Association of State Highway Officials in 1924 addressed a resolution to the Secretary of Agriculture calling upon him to appoint a board to designate a system of through routes and to devise a comprehensive and uniform scheme of marking the routes in such manner as to give them a conspicuous place among the highways of the country as roads of interstate and national significance.

United States Routes.—The 75,884 miles of road selected which will hereafter be known as United States routes include 145 routes, those running east and west being designated by even numbers and those running north and south by odd numbers. This designation has been made by a board of twenty-four State and Federal highway officials appointed in March, 1925, by the Secretary in response to the resolution of the State officials.

The more important of these routes are 10 east-and-west routes and 11 north-and-south routes which extend either entirely across the country or the better part of the country's width and length. The other routes are intermediate between these most important arteries or serve as alternate or cross-over routes. In some instances these roads terminate at the Canada line and are resumed at another point in Canada.

Markers.—All routes will be marked with the standard direction and warning signs which are of two general classes. One group, the danger and caution signs, will consist of signs of four different shapes representing as many degrees of danger. These will have a yellow background with black letters and symbols. The other group will include the standard route markers in the form of a United States shield and directional and informational signs. All signs in this group will have a white background with black letters.

The report of the Joint Board recommends that all of the signs, with the exception of the route marker, be used on all State highways in order to familiarize the public with them.

The use of the United States shield as a route marker is to be restricted to United States routes and no other type of route designation is to be permitted on such roads.

RAILROADS

By Joseph E. Cummings
Professor at University of Minnesota

ROAD AND EQUIPMENT

The railways of Classes I, II and III operated 258,444 miles of road in the United States in 1924, as compared with 259,705 miles in 1916 and 230,494 miles in 1908. The mileage of all tracks operated in 1924 was 415,099 as compared with 397,014 in 1916 and 333,646 in 1908. During the twelve months ended November 30, 1925, the Commission issued certificates authorizing the construction of 909 miles of new line and the abandonment of 652 miles of existing line.

In 1924 the total equipment of the carriers consisted of 69,459 locomotives, 2,411,462 freight cars and 57,456 passenger-train cars. This compares with 69,595 locomotives, 2,329,475 freight cars and 55,193 passenger-train cars in 1916. The figures for 1908 were 57,698 locomotives, 2,100,784 freight cars and 45,292 passenger-train cars. In comparing these figures, the following facts should be borne in mind: the average tractive power of the locomotives in use in 1924 was 39,522 pounds, in 1916 it was 32,840 pounds and in 1908, 26,356 pounds; the average freight car capacity in 1924 was 44.2 tons, in 1916 it was 40.9 tons and in 1908, 34.9 tons.

The American Railway Association reports that 1492 new locomotives were placed in service during the first ten months of 1925, with an estimate for the full year of about 1700.

EMPLOYEES

For the fiscal year ended June 30, 1925, the average number of railway employees was 1,765,170. The average annual compensation per annum was $1,624. These employees were classified as follows.

Class	Average Number	Average Compensation per annum
Officials and assistants	16,374	$5261
Professional, clerical and general:		
Daily basis	50,954	2195
Hourly basis	230,437	1491
Maintenance of Way:		
Daily basis	4,739	2900
Hourly basis	381,437	1075
Maintenance of equipment and stores:		
Daily basis	17,053	2959
Hourly basis	513,537	1476
Transportation (train and engine)	318,515	2332
Transportation (yardmasters, etc.):		
Daily basis	6,772	3107
Hourly basis	17,460	1831
Transportation (all other):		
Daily basis	26,958	1180
Hourly basis	180,934	1483
Grand Total	1,765,170	$1624

RAILROAD EARNINGS

The total railway operating revenues for Class I steam railways, excluding switching and terminal companies, for the last full calendar year, 1924, amounted to $5,921,490,100 as against $6,289,580,027 for 1923. This is a decrease of 5.85 per cent. in 1924 compared with the preceding year. Operating expenses for 1924 were $4,507,845,037 as against $4,895,166,819 for 1923, a decrease of 7.91 per cent. Net railway operating income in 1924 was $973,870,978 and in 1923 the corresponding figure was $961,955,457. This is an increase of 1.24 per cent. for 1924 over 1923. It must be borne in mind that the capital devoted to transportation was substantially increased between these two dates. The operating ratio for 1924 was 76.13 which was 1.70 less than for 1923. The largest amount of net railway operating revenue ever earned by our steam railways in a calendar year was in 1916, when the amount was $1,040,084,517. This exceeded the 1924 earnings by 6.37 per cent. The operating ratio in 1916 was 65.54 as against 76.13 in 1924. The Interstate Commerce Commission suggests that this difference in results is largely due to the increased cost of labor and materials and higher taxes. For example, in 1916, about 41 per cent. of railway operating revenue went to labor while in 1924 the corresponding figure had risen to nearly 48 per cent. The steam railway tax bill in 1916 was $163,450,852, and in 1924, $342,459,598. This is an increase of 109.52 per cent. between 1916 and 1924.

The net railway operating income for the eight months ended with August, 1925, was $651,883,260; that for the corresponding period of 1924 was $554,886,471. Thus for the period for which data are available, the year 1925 shows an increase of 17.48 per cent. over the corresponding period of 1924. The first eight months of 1925 also show an increase of 5.32 per cent. over the like period for 1923, the calendar year of largest total revenues and heaviest volume of traffic. The net railway operating income for the first eight months of 1923 was $618,964,978. These improved results have been largely accomplished by the lowering of the operating ratio, which for the eight months' period of 1925 was 75.81 as compared with 78.12 for 1924 and 78.38 for 1923. It is indicated from current reports of freight-car loadings that the traffic records of 1925 are likely to run very high.

RAILWAY CAPITALIZATION

According to the provisions of Section 20A of the Interstate Commerce Act as amended in 1920, carriers subject to the Act are required to secure permission from the Interstate Commerce Commission before issuing securities, which run for a longer period than two years. During the twelve months ending November 30, 1925, the Commission received 267 applications from railways to issue or assume liabilities in respect to securities. The total authorized during this period amounted to $907,777,854.06. This total was made up as follows:

Preferred stock	$ 17,225,330
Common stock	27,992,169
Bonds, collateral-trust ...	23,000,000
Bonds, mortgage	648,240,866.32
Debentures	7,183,944.75
Notes	40,297,029.41
Equipment obligations ...	140,048,514.58
Receivers' certificates	3,790,000
Total	$907,777,854.06

In addition, the Commission received notification, as required under paragraph 9 of Section 20A, of the issue of notes maturing within two years, in the aggregate sum of $78,270,289.56.

On November 30, 1924, the total railway capital actually outstanding amounted to $21,744,682,277. Of this $12,438,003,582 consisted of funded debt and $9,306,678,695 of stock. Adding the new issues during the current year the total capitalization as of November 30, 1925, would be $22,608,373,101. Of this total $13,256,476,907 consisted of funded debt and $9,351,896,194 of stock. These totals do not include the notes and receivers' certificates issued during 1925, as listed above.

RECOVERY OF EXCESS OPERATING INCOME

Under the recapture provisions (Section 15A) of the Transportation Act of 1920 the carriers are required, under certain conditions, to pay into the Treasury of the United States to the credit of the General Railroad Contingent Fund, one-half of all excess net operating income. A carrier is considered to have excess operating income when the amount exceeds a certain per cent. (now 5¾) of the value of their property devoted to the service of transportation. During the ten months ending November 30, 1925, thirty-three carriers paid into this Contingent Fund the total sum of $732,448.34. Prior to that time a total of $4,955,197.27 had been paid in to the fund,—making the total of such payments, up to November 30, 1925, $5,687,645.61. Interest earnings on the fund have brought the total up to $5,941,339.14. As the bulk of these payments has been made under formal protests and reservations this fund has not been available for the purposes contemplated by the statute.

RAILWAY VALUATION

The valuation of the railroads as required by the 1913 amendment (Section 19A) to the Interstate Commerce Act has advanced more rapidly during 1925 than for several preceding years. The slacking in the valuation work was due to inability to maintain a proper force during the war and to lack of funds since the end of the war. A bill approved, March 3, 1925, carried a substantial increase in funds for valuation work. These additional funds were provided in order to carry out a plan to complete the valuation work within a three-year period, beginning July 1, 1925. By October 31, 1925, the Bureau of Valuation had completed the preliminary underlying reports (Accounting, Engineering, and Land) on practically all the steam railroads in the United States. Of the underlying reports completed on October 31, 1925, 63 per cent. of the accounting reports, 70 per cent. of the engineering reports, and 64 per cent. of the land reports have been corrected and made final for use in preparing tentative valuation reports. Tentative valuation reports have been issued on 51.46 per cent. of the mileage and the work on the remaining mileage is well advanced.

Hearings on protests against tentative valuations were concluded during the year in 62 cases covering 25,784 miles of road, or 10.6 per cent. of the total mileage. This brings the total number of cases in which hearings have been completed up to 212, embracing 43,600 miles or approximately 18 per cent of the total. Sixty-four cases, covering 26,469 miles of road, have been partly heard.

During 1925 fifty-three final value reports, representing 4,929 miles of road, were issued. This brings the total number of miles on which final value reports have been issued up to 9,325 or 3.8 per cent. of the total mileage. In addition, valuation reports covering 1,733 miles of road have become final, during 1925, through lack of protest. Reports are now final on 5.5 per cent. of the entire mileage of the country.

The Interstate Commerce Commission's valuation order No. 3 requires carriers to keep a record of additions, betterments, and retirements made subsequent to the date of the primary valuation and to render annual reports covering such matters. During the year a large force has been engaged in checking these reports in Washington and also on the carrier's property.

HOCH-SMITH RESOLUTION

By joint resolution of Congress, approved January 30, 1925, the Commission was authorized and directed to make a thorough investigation of the rate structure of common carriers subject to the Interstate Commerce Act. The resolution is as follows:

"*Resolved by the Senate and House of Representatives of the United States of America in Congress assembled.* That it is hereby declared to be the true policy in rate making to be pursued by the Interstate Commerce Commission in adjusting freight rates, that the conditions which at any given time prevail in our several industries should be considered in so far as it is legally possible to do so, to the end that commodities may freely move.

"That the Interstate Commerce Commission is authorized and directed to make a thorough investigation of the rate structure of common carriers subject to the interstate commerce act, in order to determine to what extent and in what manner existing rates and charges may be unjust, unreasonable, unjustly discriminatory, or unduly preferential, thereby imposing undue burdens, or giving undue advantage as between the various localities and parts of the country, the various classes of traffic, and the various classes and kinds of commodities, and to make in accordance with law, such changes, adjustments, and redistribution of rates and charges as may be found necessary to correct any defects so found to exist. In making any such change, adjustment, or redistribution, the commission shall give due regard, among other factors, to the general and comparative levels in market value of the various classes and kinds of commodities as indicated over a reasonable period of years, to a natural and proper development of the country as a whole, and to the maintenance of an adequate system of transportation. In the progress of such investigation the commission shall, from time to time, and as expeditiously as possible, make such decisions and orders as it may find to be necessary or appropriate upon the record then made in order to place the rates upon designated classes of traffic upon a just and reasonable basis with relation to other rates. Such investigation shall be conducted with due regard to other investigations or proceedings affecting rate adjustments which may be pending before the commission.

"In view of the existing depression in agriculture, the commission is hereby directed to effect with the least practicable delay such lawful changes in the rate structure of the country as will promote the freedom of movement by common carriers of the products of agriculture affected by that depression, including livestock, at the lowest lawful rates compatible with the maintenance of adequate transportation service. *Provided,* That no investigation or proceeding resulting from the adoption of this resolution shall be permitted to delay the decision of cases now pending before the commission involving rates on products of agriculture, and that such cases shall be decided in accordance with this resolution.

"Approved, January 30, 1925."

Pursuant to that resolution the Commission instituted, on March 12, 1925, a general investigation in accordance with this legislation. Hearings have been conducted throughout the year, but because of the broad scope of the investigation the work will require a considerable amount of time for completion.

RAILWAY CONSOLIDATION

In accordance with the requirements of Section 5 of the Transportation Act of 1920 the Interstate Commerce Commission prepared a Tentative Plan for the consolidation of all the railways into nineteen systems. This plan was served on the carriers August 3, 1921. Hearings were then conducted on the plan at various points throughout the country from April 24, 1922, to December 4, 1923. Examiners of the Commission were present at all these hearings and one or more of the Commissioners were present at most of them. February 9, 1924, was the last day on which briefs could be filed. During this period, eighty days were devoted to taking testimony and six days to hearing oral arguments. Thus, a total of eighty-six days were devoted to making the record on which the Commission is to base its "final" plan.

On February 4, 1925, the Commission addressed a letter to the chairman of the Senate Committee on Interstate Commerce in which the majority of the Commissioners expressed doubt as to the wisdom of the provisions of the law which now require them to adopt a complete plan to which all future consolidations must conform. They stated that they believed that results as good, and perhaps better, are likely to be accomplished with less loss of time if the process of consolidation is permitted to develop, under the guidance of the Commission, in a more normal way. On page 13, of its annual report for 1925, the Commission suggests that existing law be amended so as to accomplish the following results:

"(1) Relieve the Commission from its present duty of adopting a complete plan of consolidation.

"(2) Make unlawful any consolidation or acquisition of the control of one carrier by another in any manner whatsoever, except with the specific approval and authorization of the commission. The purpose of this provision is to make certain that the process of consolidation will in all respects be subject to the control and guidance of Federal authority. Without such a prohibition it will be claimed that such consolidations or acquisitions of control as are not in conflict with the Federal antitrust laws may be effected, as was done in the Nickel Plate case, under State authority and without Federal approval. Whatever the merits of the Nickel Plate consolidation, it must be obvious that the possibility of consolidations or acquisitions of control thus consummated means a division of authority and responsibility which is likely to be destructive of any well-ordered and consistent control of the process of consolidation in the public interest.

"(3) Give the commission broad power to approve or disapprove such consolidations or acquisitions of control as are proposed. Before approving, the commission must find that the consolidation or acquisition—

"(a) Will be in the interest of better service to the public, or economy in operation;

"(b) Will not unduly restrain competition or be in any other material respect inconsistent with the public interest; and

"(c) Will conform to the provisions of paragraph 4, which prohibit a capitalization of the consolidated company in excess of property value.

"It may seem unduly drastic to require a finding that the consolidation or acquisition will not be inconsistent with the public interest in any material respect, but it will be noted that the commission is not restricted to the approval or disapproval of the consolidation or acquisition as proposed, but is authorized to approve 'with such modifications and upon such terms and conditions' as it shall find just and reasonable. If what is proposed will promote the public interest in certain respects but not in others, it need not be wholly rejected but may be approved in a modified form which will eliminate the objectionable features.

"(4) The commission is specifically authorized to disapprove a consolidation or acquisition upon the ground that it does not include a carrier, or all or any part of its property, which ought to be included in the public interest and which it is possible to include upon reasonable terms. One of the criticisms of such consolidations or acquisitions as have been proposed or suggested has been that they do not take care of the weak lines, although the merger of weak with strong lines is one of the ends which Congress has apparently had in mind. The specific provision above described will, it is thought, enable the commission to require attention to be directed to this phase of the matter, which otherwise might be neglected. The commission is also specifically authorized to make it a condition of any consolidation or acquisition that 'existing routes and channels of trade and commerce shall be maintained.' This provision has been inserted to remove such doubts as have been raised with respect to our power to attach such a condition.

"(5) The commission is required to preserve 'all records and other evidence heretofore taken and now in the files of the commission, under the terms of this section as heretofore enacted' and is authorized to utilize such records and evidence in reaching its conclusions with respect to any consolidation or acquisition proposed. This provision will enable the Commission to avail itself of the very valuable information which has been gathered in connection with the consolidation-plan proceeding.

"(6) The provision now in subparagraph (b) of paragraph 6 of Section 5 has been retained in somewhat modified form. This is the provision which limits the total capitalization of the consolidated company to the value of the combined properties. The thought underlying the modification is that it may be possible to determine value for the purposes of this provision more expeditiously than is possible under the valuation procedure prescribed in Section 19A. It should be understood, however, that even with this modification this provision is likely to cause material delay in the process of consolidation. The safeguard provided by the provision is a desirable one and the question which must be faced is whether delay in accomplishing consolidations is more objectionable than the absence of such a safeguard."

In its annual report for 1924 the Commission stated that the work of preparing the complete (final) plan of consolidation was progressing. However, on the basis of the letter of the Commission to the Senate committee, it would appear probable that the final plan will not be announced until Congress has had time to consider the proposed amendments to the consolidation provisions of the regulating Act.

MERCHANT MARINE

By Peter Bain

Editor of "Shipping," New York

CONDITIONS

Post War Period.—The marine transportation affairs of the world had probably reached the lowest ebb ever recorded in 1925. The reaction from the immediately previous years of uncertainty and the contrast with the hectic boom years that lasted through and directly followed the Great War had made themselves acutely apparent during the twelve dull months that have just come to a close.

Shipping men had just passed through a lean and hungry period of depression in all departments. Rates had been all "shot to pieces" and as regards Conferences to maintain or at least steady them, these, figuratively speaking, passed away over night. Trans-Atlantic steamship lines particularly, operating under the heavy handicap of huge overhead and small aggregate traffic—passenger and freight—together with a further raising of the Immigration Law barrier, had a hard and strenuous time in making ends meet. In not a few cases, an alarming gap appeared between income and expenditure. Even solidly substantial and old established ship lines abroad that had always earned a fair return on the invested capital were in numerous instances lucky to break near even.

When 1925 dawned, the great machine created because of our wartime emergency still lumbered along with its topheavy burden of unnecessary personnel, although valiant attempts had been made in the preceding twelve months to reduce it and not without some considerable measure of success. Some of the best shipping brains available had been drafted for various responsible positions and it cannot be denied that they set themselves heroically to their task.

Coastwise Trade.—Our protected coastwise trade, probably more than any other, was showing renewed vitality and so far had not been too crowded to allow of fair earnings being made by the few lines participating. The depression in practically every other direction made scouting for remunerative opportunity the serious business of those firms whose fleets were gradually being laid up, either because of lack of traffic or the utter impossibility of even meeting overhead at prevailing rates. During the past twelve months the result of the scouting has been very much in evidence; in a word, our coastwise and intercoastal trade has not only maintained its high degree of traffic reputation but has increased it many-fold, largely, we should say, because of the many new lines now engaged in it and the vastly increased number of scheduled sailings offered. Our coastal and intercoastal services are becoming, if anything, just a bit crowded, not so much for comfort or sea room as for satisfactory revenue to go round.

Foreign Trade.—Government-owned ship services continue to be maintained on regular schedule between all leading United States ports and the principal trade centers and ports of the world but, unfortunately, on a far from remunerative basis in most cases, whether the service be combination passenger and freight, or freight only. Foreign lines still retain the major portion of our export and import commerce, notwithstanding the earnest, well-directed and concentrated effort being made to secure for American ships their equable share. Establishment and permanent consolidations of such an eventuality are, of course, impossible of "overnight" achievement, so to speak, and perhaps we are finding it so.

Long establishment, intimacy with every phase of and factor entering into marine transportation are all on the side of and favorable to our competitors and, while there is much we should be able to show them (commerce and industry, to which it has applied itself), the more familiar we allow ourselves to become with their methods and devices and the more we appropriate their ideas when worthwhile and applicable, just so much sooner will our maritime ambitions be realized, our revenues and expenditures occupy their proper relationship and our national pride and prestige be soothed and reasserted, respectively.

Success in Private Ownership.—Private owners are now displaying a much greater interest in Government-owned ships than at any time since hostilities ceased in Europe, reasoning, probably, that with prices right, no better way of getting Washington out of the shipping business could be devised. Again, it is generally agreed that the realization of our dream of and ambition for a merchant marine worthy of our world importance nationally, must rest on the shoulders of private ownership, and it certainly appears that the latter have so decreed. The past year witnessed the greatest speeding-up effort yet made to place overseas services entirely in private hands and while the actual transfers accomplished may not have fully measured up to anticipations, yet judging from the number of sale transfers pending and projected, the year 1926 promises to be a banner one.

Overseas Sales to Private Owners.—Bearing then in mind our desire to possess a merchant marine in world trade, relatively and ultimately as active, large and prosperous as our coastwise and intercoastal fleets, it does not seem as though we had gotten as far as we had hoped and anticipated. Our coastwise and intercoastal fleets, it will have been noted, are privately owned and operated. This holds good to only a very limited extent in our world trade and commerce. During the past year, only a few individual vessel units and small fleets, comparatively, for overseas trade, were transferred to private owners, and in all cases with the stipulation that American Registry be retained for a number of years. Two examples of transfer from Government ownership to private ownership, for ocean or international trade, were those of the American Export Line Mediterranean Service and fleet to the Export Steamship Corporation of New York City, and the Pan-American Line South America Service and fleet to the Munson Steamship Lines. The purchasers in each instance had been operating for the Shipping Board under what is known as the MO4 managing agency agreement. Another important sale, consummated in almost the closing hours of 1925, was that of the American-South Africa Line, consisting of 5 ships averaging 8,600 dead weight tons, to John M. Franklin, representative of a powerful corporation being formed with the above fleet nucleus to operate and maintain a regular service between American and South African ports. The sale price was $780,000.

Investors Showing Interest.—The passing of our Government-owned fleet into private ownership suggests immediately the passing of money from the latter to the former. Times have most surely changed materially in less than a decade, for then it was a frequent and favorite argument of interests hostile to the development of an American Merchant Marine that no money could be pried loose for investment in American shipping, of all shipping, although readily available for and handed out to, if not less worthy objects, then less patriotic ones. It may not, however, be as generally known as it should that a great deal of American money is now being invested in ocean steamship services and enterprises and not a little is being placed with enterprises under foreign flags, notably the British, Dutch, German and Scandinavian. It cannot be longer pretended that ocean trade is such that only the "cheap money" of nations of Europe can profitably undertake it. Much important financing of American steamship enterprises has been successfully carried out since 1921 in spite of which there is money available on occasion for the use of European shipowners.

Get-Together on Merchant Marine.—Possibly at no time since completion of our national war-time fleet has the disposition of that fleet so exercised the minds of our business community. Early in the year, the Chamber of Commerce of the United States sought the coöperation of every interest directly or indirectly related to ships and shipping in formulating a plan or plans whereby greater progress would be assured in the development of our foreign trade and, through the latter, the greatest possible utilization of vessel tonnage of American construction and registry. Regional conferences were held during the summer and early autumn months in the principal cities of the Great Lakes, the West, the Pacific Coast, the Southern States and in New York City.

Committees.—The result of the views and recommendations advanced at these regional conferences by representative American business men was embodied through the agency of the National Chamber of Commerce in the reports of four committees as follows: (1) Relation of the Merchant Marine to American Foreign Trade and National Defense; (2) Government Regulatory and Administrative Relations to the Shipping Industry; (3) Government Aid to Shipping; (4) Disposal of Government-Owned Merchant Ships. These reports, in brief, emphasized the need of placing the whole government-owned merchant fleet into private hands as soon as possible without sacrifice of any of the essential routes of commerce, also the vital need of a merchant marine for national defense, much in excess of our coastwise tonnage. They also strongly upheld national aid to American overseas shipping—the one unprotected American industry—not through a general ship subsidy system but through mail subventions and contracts compensating regular lines and services.

Conference Findings.—The reports came up for discussion at a National Merchant Marine Conference assembled in November at Washington, at which the representation of shipping men was a minor quantity. The majority of conference members consisted of manufacturers, merchants and bankers, from North, South East and West, the Middle West having a notable quota. In a carefully prepared address, Secretary Hoover expressed his views on the type of merchant marine needed by the United States and the organization best suited for Government marine activities. He asserted that the Shipping Board had been burdened by too diversified responsibilities and that every member of the Board, if left alone, would probably have made a success of our merchant marine. His judgment was that the whole fleet and associated property should be transferred to the Fleet Corporation and that the President of the latter should be appointed by the President of the United States, subject to confirmation by the Senate and should be solely responsible to the President. The function should not be incorporated into the Department of Commerce which is a service agency to the whole American Merchant Marine, whether private or governmental. Secretary Hoover's recommendations as a whole were very favorably received by the members of the Conference and as regards the reports of the various committees these were approved with but slight changes and affirmed as the expressed views of American business.

Pending Legislation.—An effort will doubtless be made during the present session of Congress and the Senate to secure consideration of the reorganization program of Secretary Hoover, indicated above. That there will be obstacles to overcome is certain but, in view of the importance of the issue, an enlightened settlement is hoped for. The problem requires deliberate and impartial treatment.

Protection of Coastwise Trade.—The past year has been a remarkable one in many general respects. Assertion of our determination to uphold our coastwise laws against all comers was demonstrated when the Lamport and Holt Steamship Co. of Liverpool, England, was fined $110,000, for what was considered a gross violation of the Coastwise Laws of the United States, when their vessel the *Voltaire*, transported from Philadelphia to Boston and return via the ports of Halifax and St. John, several hundred members of the Order of Elks who went to Boston to attend the annual meeting of their organization. The amount of the fine was later reduced to $25,000 and was paid. This is regarded as a salutary warning to foreign steamship interests in general against making any further effort to ignore or attempt to nullify the coastwise navigation laws of the United States.

PANAMA CANAL

Tolls.—Due to the great increase in intercoastal traffic, already noted, small wonder is it that the Panama Canal is becoming all the time a more prosperous undertaking. Again, notwithstanding that American ships lead all others in number and tonnage, there is abundant evidence that its popularity is increasing among foreign nations, as a business necessity of course. The question of tolls is meantime a burning one as between the Canal authorities and American steamship owners, the former recommending a rate of $1.00 per ton Panama Canal measurement on loaded vessels and 60 cents per ton on vessels in ballast passing through the Canal if a bill be passed establishing the Panama Canal system of measurement as the sole basis of tolls. The American steamship owners want a loaded rate of 80 cents per net ton for vessels, with a proportionate rate for vessels in ballast.

Finances.—Panama Canal revenues during the fiscal year 1925 decreased somewhat, but the net revenue from tolls and miscellaneous sources still stands at the impressive figure of $13,465,924.72, as compared with $16,307,948.50 in 1924 and $10,001,066.50 in 1923. American shipowners insist that it should suffice to pay the operating expenses of the Canal, an interest rate of 3 per cent. on the cost, and make adequate provision for amortization of the expense of shipping the greater part of which flies the American flag.

WATERWAY AND COASTWISE COMMERCE

By Harry Taylor

Major General, U. S. A., Chief of Engineers, War Department

Inland Waterways.—The following shows freight traffic for 1924 of waterways under improvement by the Federal Government, excluding short deep stretches of navigable rivers (like the lower Hudson and Delaware) which are really approaches to seaports:

TABLE OF IMPROVED WATERWAYS

Waterways	Short Tons	Value
Hudson River, middle stretch	9,721,553	$ 121,519,878
Hudson River, upper stretch	1,700,715	111,393,507
Delaware River, above Philadelphia	3,186,590	14,027,229
Chesapeake-Delaware Canal	683.206	42,086,886
Waterways, Norfolk to Sounds of North Carolina	293,893 497,393	4,850,973 17,427,267
St. Johns River, above Jacksonville	306,681	17,429,878
All others, Atlantic Coast	12,888,342	482,459,887
Mobile-Tombigbee-Warrior System	1,105,260	16,263.186
Southern Louisiana Waterways (excluding Mississippi River)	2,780,843	57,815,552
All others, Gulf Coast	2,929,417	57,005,433
San Joaquin River	727,499	38,185,313
Sacramento River	1,796,105	58,662,997
Columbia River, above the Willamette	1,146,106	25,109,905
All others, Pacific Coast	11,375,380	164,597,550
Mississippi River, below Vicksburg (excluding ocean commerce)	5,809,725	178,773,978
Mississippi River, Memphis-Vicksburg	1,666,440	119,408,180
" " Cairo-Memphis	1,153,021	80,055,571
" " St. Louis-Cairo	738,728	36,734,217
" " above St. Louis	769,139	14,265,553
Ohio River	10,866.683	128,356,018
Monongahela River	21,878,815	123,355,071
Allegheny River	4,339,511	11,896,245
Kanawha River	901,183	5,756,891
All others, Mississippi System	7,627,434	101,943,897
Detroit River (through commerce of the Great Lakes)	80,073,850	1,200,307,001
All others in U. S.	7,758,405	517,111,358
Total	194,721,917	$3,746,799,431
Total, corrected for duplications because of commerce moving over two or more waterways	173,200,000	$3,446,000,000

The figure for the Detroit River does not give the entire Great Lakes commerce, much of which (classified as foreign, coastwise or internal) did not pass through that channel. The total corrected Lakes commerce was 109,831,279, valued at $1,968,533,514.

A table on page 582 shows the total of corrected internal waterways commerce in recent years, including only that part of the Lakes commerce passing through the Detroit River.

The following is for internal waterways other than those under improvement by the Federal Government:

Waterways	Short Tons	Value
Cape Cod Canal *	922,062	$221,116,808
New York State Barge Canal	2,032,317	75,095,000
Lehigh and Delaware Division Canals, Pa.	297,612	1,559,511
Chicago Sanitary Drainage Canal	530,917	2,016,903
New Basin Canal, La.	402,643	2,006,426
All others of record	1,066,673	25,532,262
Total	5,252,224	$327,326,910

* It is questionable whether this should be classified as an inland waterway.

Panama Canal Trade.—Below are tables showing total traffic and intercoastal commerce through the Panama Canal in recent years:

TABLE OF COASTWISE COMMERCE
(Including Intercoastal)

Port	Tonnage, Both Ways	Value
Portland, Me.	1,779,283	$ 52,980,534
Boston	9,951,215	304,146,786
Providence	3,473,998	456,806,396
New York	29,573,952	2,328,035,883
Philadelphia	9,411,014	500,684,626
Baltimore	4,174,718	345,831,129
Norfolk-Newport News	12,867,091	419,317,302
All others, Atlantic Coast	22,056,383	1,595,720,072
New Orleans	2,520,435	118,364,603
Galveston, Houston, Texas City	8,286,719	776,430,626
The Sabine ports	9,836,277	244,727,778
All others, Gulf Coast	3,603,562	145,285,684
Los Angeles	17,972,065	517,486,659
San Francisco Bay and Harbor	16,172,115	867,889,166
Portland, Oregon	2,779,424	189,461,644
Tacoma	3,052,584	83,509,529
Seattle	6,414,577	341,139,159
All others, Pacific Coast	9,446,100	205,486,200
Hawaii, Porto Rico, and Alaska	3,736,912	445,243,464
Total	177,108,424	$9,938,547,240

URBAN AND INTERURBAN TRACTION

By Henry W. Blake

Senior Editor, Electrical Railway Journal

Patronage.—Since 1917, the electrical railways of the country have not shown the annual percentage increase in number of passengers carried that was usual in earlier years. From 1902 to 1907, the average annual increase was 11.2 per cent.; from 1907 to 1912, it was 5.7 per cent.; from 1912 to 1917, it was 3.7 per cent.; from 1917 to 1922, it was 2.4 per cent. Statistics published by the American Electrical Railway Association show that for 370 companies, from which figures had been obtained, consisting mostly of the larger companies, the revenue passengers decreased 1.18 per cent. in 1924 as compared with 1923. The figures include the companies in New York City, where there was an increase in passengers carried of about 3.55 per cent. If the figures for passengers carried in New York are deducted from the 1924 and 1923 figures, the decrease in 1924 would be 2.26 per cent. The falling off in traffic is due principally to the competition of the private automobile, and is most noticeable on electric railways in the smaller cities and on the interurban lines.

This rate of decrease will probably grow less or stop, because city streets are constantly becoming more crowded, and the measures which will have to be adopted to relieve traffic congestion will necessarily favor the type of vehicle which utilizes the street surface area more efficiently per passenger carried than any other. This is the electric car. Many cities have already passed stringent nonparking ordinances covering the downtown business streets, thus relieving the interruptions to street rail traffic.

Bus Operation by Electric Railways.—During 1925, electric railway companies have greatly increased the number of buses operated by them. At the beginning of the year the number of buses operated by electric railway companies in the United States and Canada was approximately 2,462, about twice the number operated the year previous. Statistics compiled by the American Electric Railway Association show that in September, 1925, 251 electric railway companies in the United States and Canada were operating 4,452 buses over 12,060 miles of route. Of these 115 were giving city or suburban service, 48 were rendering purely interurban service and 39 were giving combined city or suburban and interurban service. Information was not available on the remaining 49 companies.

The local electric railway is the logical operator of the bus lines and possibly even of the taxicab service in the general territory served by it. One reason is that it already has an organization familiar with the transportation needs in the community. Furthermore, it can avoid duplication of bus and trolley routes, and thereby give more economical and efficient service. The bus service given by electric railway companies is of many types, varying from service similar to that given by the trolley cars to a de luxe city express service as in Kansas City, where fares up to 25 cents are charged for a city run. Some railway companies are also conducting bus tours of one-day or longer duration, for example, in Milwaukee and Baltimore.

At the convention of the American Electric Railway Accountants Association in October, 1925, a standard classification of bus accounts was adopted, fulfilling a need which had been felt for several years. This classification will give all those interested in keeping bus costs a basis for securing comparable bus cost data.

Early in the year the United States Supreme Court held that the degree of regulation which state public service commissions can exercise over interstate bus lines is very limited. Previously, the Interstate Commerce Commission had declined to assume the regulation of these lines, on the ground that it was without authority to do so. As a result, unregulated interstate buses have devoloped in large numbers, competing with steam and electric railway common carriers which have long been under governmental control. It is probable that legislation bearing on this point will be introduced at the coming session of Congress.

Types of Cars.—The expansion of bus service by electric railway companies has been one of the main developments of the year in local transit matters. Another has been advances in car design. Up to the development of the one-man safety car, ten years ago, there had been little change for many years in the design of car bodies. The early one-man cars disclosed the possibilities of light-weight construction and saving in car personnel; and improvements have followed fast. A tabulation made early in 1925 of cars purchased in 1924 shows that the most popular design for city lines was the one-man two-man car, which represented over 60 per cent. of all passenger cars bought, except those for subway and elevated lines and other train service. For such lines the articulated type is growing in popularity although as yet it is hardly more than in the experimental stage.

During 1925 the Brooklyn-Manhattan Transit Corporation added four triplex articulated cars to its rolling stock for rapid transit service. Each so-called "car" consists of three car bodies, which are mounted on four trucks. The overall length of each train unit is 137 feet. Articulated cars with two or three car bodies are also being tried out on a number of surface lines. The Milwaukee Electric Railway & Light Company was a pioneer in this kind of cars, using two bodies on three trucks, and in January, 1925, was rebuilding 384 bodies to form 192 duplex articulated units. Articulated cars for surface lines have also been used during the year in Detroit, Baltimore, Brooklyn and Chicago. Among the advantages claimed for this type of construction are reduction in weight, noise, first cost and operating cost, and greater comfort and convenience to passengers.

Another important development of the year in car design was the competition conducted by the Grand Rapids Railway for "light-weight noiseless" cars, by securing the construction from three car-builders of one car each, in which these two features, with comfort to passengers, received primary consideration. The cars furnished will undoubtedly leave an impress on car design of the future.

Standardization. — Present sentiment seems to be that it would be impracticable, or inadvisable even if practicable, to develop a so-called standard car, suitable for all lines, but that most of the economies possible in manufacturing from such a standard can be secured through the standardization of certain basic car dimensions. This is the direction on which the committee on unification of car design of the American Electric Railway Engineering Association has been working. Thus, it is aiming to establish for city cars a standard depth of side girder plates, standard spacing of post centers, standard sizes of glass, etc. Such standards would enable builders to fabricate most of the parts of car bodies on a quantity production basis.

Substations.—Outside of car design, the principal engineering development during the year has been an increase in the number of automatic substations. Some of these have been installed as substitutes for manually operated substations and some as additional stations to reduce line loss.

Fares.—There has only been a slight increase in the average fare on city lines during 1925. The Richey index for January, 1925, gave the average as 7.24 cents, whereas the figure for November, 1925, was 7.30 cents. This average is weighted in accordance with the population of the various cities in which the lines operate, and includes all of the cities in the country of 50,000 population or more, except New York City. While the uniform fare with free transfer remains the one most generally employed in urban service, there has been a tendency on some lines toward lower fares for the very short distance rider and the very frequent rider. Conspicuous examples of the former practice include Boston, where the local rider in the suburbs pays 6 cents, while if he uses the rapid transit lines, he pays 10 cents; the Public Service Company of New Jersey, which has 5-cent zones, generally coincident with city boundaries; and San Diego, which has an inner 5-cent zone and an outer 5-cent zone. In general, transfers are not given where only 5 cents is charged. The most conspicuous effort to give fare concessions to the frequent rider is through the unlimited-ride weekly or Sunday "pass." Conspicuous examples of companies using this plan are the Chicago Elevated Lines and the Pittsburgh Railways Company.

Franchises.—The most important new franchise adopted during the year was that in Cincinnati which went into effect Nov. 1, 1925. It is of the service-at-cost type, with a fare control fund having a lower limit of $200,000 and an upper limit of $600,000. The city retains the right of purchasing the property each year for the aggregate par value of the capital stock and reducible debt outstanding. Two important francise settlements were rejected by popular vote during the year, both on April 7. One was in Milwaukee, where the proposed franchise was on a service-at-cost basis, with participation of the city in the management of the affairs of the company in the metropolitan area. The other was in

Chicago, where a unified transportation system, to be owned by the city, and to include a subway, was under consideration.

Accident Reduction.—The large number of automobiles on the streets has greatly increased the problem of accident prevention. While accidents from boarding and alighting and causes other than in connection with automobiles have decreased as a rule, those in which automobiles are involved have in many places increased. In consequence, most companies now pay great attention to intensive campaigns both among their employees and with the public to promote the idea of safety. A number of companies now use one kind or another of bonus plan to encourage employees to make good safety records.

Interurban Railways.—The remarks just made about accident reduction apply equally to urban and interurban railways. The latter are also paying great attention to improved car design, especially in the way of lighter cars and more comfortable cars. Interurban roads are also paying more attention to developing freight, and the revenue from this source during 1925, it is estimated, will amount approximately to $65,000,000. The most important development in the interurban freight business in the recent past has been the establishment of through rates and joint transportation arrangements, not only between connecting electric lines but also with steam railroads and boat lines. One group of interurban roads in Michigan, Indiana and Ohio has a single tariff, naming through competitive rates between all stations served by them and covering approximately 5,000 miles of road. Progress along similar lines has been made by a group of electric railways operating in western Pennsylvania.

Statistics.—The last census report of electric railways was taken in 1922, but this report was not published until February, 1925. It showed the following statistics for urban and interurban roads during 1922: Number of companies, 1,200; miles of single track operated, 43,932; persons employed by operating companies, 300,523; passengers carried, 15,347,519,966; railway operating revenues, $925,477,485; railway operating expenses, $678,563,170; net revenue from railway operation, $246,914,378; gross income, $256,464,838; net income, $57,187,612; gross capitalization of operating and lessor companies, $5,446,794,547; net capitalization on account of electric railways (excluding investments in securities and non-operating property), $4,661,923,873. There were 88,707 revenue cars, of which 77,301 were passenger cars.

The table below gives statistics for 1923 and 1924, compiled by the American Electric Railway Association for 370 companies, which operate, however, about 75 per cent. of the total track and account for nearly 85 per cent. of the gross revenue of the industry:

COMBINED OPERATIONS OF 370 COMPANIES

	1924	1923	Per Cent. Increase or Decrease
Operating revenue	$786,530,422	$794,252,546	— 0.98
Operating expense	581,288,567	584,674,342	— 0.58
Net operating revenue	205,241.855	209,578,204	— 2.07
Operating ratio	73.90%	73.61%	+ 0.39
Miles of track	32,083.3	32,032.5	+ 0.15
Revenue passengers	10,890,887,334	10,906,853,081	— 0.15
Total passengers	13,483,075,342	13,642,898,110	— 1.18
Car-miles (rev.)	1,843,827,779	1,823,941,852	+ 1.09

AERONAUTICS

By Godfrey L. Cabot

President, National Aeronautic Association

Government Activities.—The United States Government has created five separate government agencies carrying on important Aeronautical work, as follows:

1. The United States Army Air Service.
2. The Navy Bureau of Aeronautics (in which is incorporated the Marine Corps activity).
3. The Air Mail Service of the Post Office Department.
4. National Advisory Committee for Aeronautics.
5. Department of Agriculture.

U. S. Army Air Service.—This Service is a separate combatant branch of the Army, consisting of 904 officers and 8,950 enlisted men, a total personnel including flying cadets, of 9,854 as of June 30, 1925.

Instruction.—There are seven schools, including a technical school, a primary and advanced flying school, a tactical school, a balloon and airship school, an engineering school and an inspectors' school. These schools are under the direct supervision of the Chief of the Air Service. A number of fields located in many places throughout the United States occupied by tactical units are under the immediate command of Corps Area Commanders of the U. S. Army.

Aid to Commerce.—In addition to its work as a part of the National Defense, the Army Air Service has been extremely active since the war in demonstrating the value of aeronautics as a peace-time agency. Officers and planes have been loaned to the Department of Agriculture. Much attention has been given to the technical development of aircraft which has its peace-time value in connection with commercial and civilian aviation.

A good example is the coöperation of the Air Service Engineering Division, located at McCook Field, Dayton, O., with the aircraft transportation and aircraft manufacturing industries. This Engineering Division has been largely responsible for the development of military aircraft and equipment, which is the best in the world in point of performance and has, at the same time, acted in the capacity of consulting engineer and research department for general aeronautical development.

In an effort to promote, popularize and stimulate commercial aeronautics, the Army Air Service has taken part in many contests and has brought to the United States a large number of world's records.

Mapping.—Another important activity, that of photographic mapping, has been successfully carried on by the Army Air Service, and has stimulated the birth and growth of a number of civilian organizations which now make a regular commercial enterprise of such work. Much of the apparatus now available for such use was first developed either by or under the supervision of the Army Air Service.

Agricultural Department.—Though of less immediate scope and importance than some other departments, it is fitting, next, briefly to sketch the air work of the Agricultural Department because this has been and is so largely dependent on the good will and zeal of the Army Air Service. The Army Air Service has loaned men and planes to the Agricultural Department for forest patrol and much good work has been done. It has been found, however, that there are so few airdromes, and other facilities that this work is unusually hazardous and chiefly valuable as an adjunct to other services, such as the use of lookout towers, etc.

Much has, however, been learned on the control of fires over large areas; and $50,000 has been appropriated this year for special work in particular localities such as patrol whenever the sky is hazy and the scope of vision of lookout towers inadequate.

Spraying.—Another very important use that has been developed by the Agricultural Department is the use of airplanes for distributing arsenate of calcium mixed with a large surplus of lime over the cotton fields of the South to exterminate the boll weevil, the army worm and cotton leaf caterpillar. It has been found that where cotton is cultivated over large areas, not only better, but, also, cheaper service can be obtained by distributing the poison from airplanes.

Through this work of the Agricultural Department, contracts have been made for five treatments of a very large area of southern cotton fields by a firm of aircraft manufacturers who have developed for this purpose a very efficient special machine carrying each 1,000 pounds of poison. When it is considered that there are probably over 20,000,000 acres of cotton fields in the South in such large areas as to make treatment from the air economical, and that it takes something like five treatments a year, it would seem that this industry has a truly immense future before it. The demand for this service apparently exceeds the supply so that new planes must be built to take care of the peach orchards which, also, seem to be more conveniently protected in this way than in any other from certain pests that destroy them.

Naval Aeronautics.—The Navy Bureau of Aeronautics differs from the Army Air Service in that it is an integral part of the fleet, the Navy having no separate combatant arms. Pilots, mechanics and aircraft units form the naval air organization afloat and are under the immediate command of the vessels or fleet to which they are attached. The National Aeronautic Association has suggested the desirability of giving more attention to combatant use of aircraft, organization of air attack and the development of bombing attack. The subject of Naval aeronautics is treated at length in the Division on Defense and Armament.

National Advisory Committee.—This is a body of twelve members appointed by the President, serving without compensation. Five are appointed from private life and the others come from the War and Navy Departments, the Weather Bureau, the Bureau of Standards and Smithsonian Institution. This Committee studies the problems of flight, aircraft construction, and gives advice to aircraft manufacturers and others therein interested. It has a well-equipped research laboratory located at Langley Field, Hampton, Va., one of the stations of the Army Air Service. The N. A. C. A. functions through an executive committee and standing technical committees in coordination with other Government air agencies and the public. The Committee investigates in its own laboratory the fundamental principles of aeronautics, and allocates work on particular technical problems among other Governmental and private institutions. It publishes the results of its own work and collects aeronautical data from other agencies throughout the world. Its reports are available, not only to Government departments, but to the public at large, through pamphlets which may be purchased for a nominal sum from the Public Printer.

Other Governmental Activities.—The work of the U. S. Bureau of Standards and the U. S. Weather Bureau have been of great value and assistance along aeronautical lines. Much aeronautical work has been done by the Bureau of Standards in their well-appointed laboratories at the request of the War and Navy Departments, the N. A. C. A. and of the National Aeronautic Association.

The Aeronautical Board is a joint Army and Navy board, organized to coördinate the activities of these military branches and avoid needless duplication. It acts as a clearing house of information, giving each the benefit of all that is known by the other and facilitating the cordial coöperation which has marked the history of these two Government departments. Outstanding instances of this coöperation are the World Flight, and the making of contracts for aircraft by one department, and the placing of the resultant aircraft at cost with the other, thereby securing a better price and cheaper production than would have been possible had they worked independently.

The Weather Bureau has furnished special reports and weather predictions for use of those who navigate the air, and arranged to have Aviation officers present at certain of its stations to receive daily and hourly reports of air conditions for the benefit of certain Governmental activities heretofore mentioned. Meteorological investigations which are of great importance to aerial navigation have been greatly assisted by the work of this Bureau.

The Forest Products Laboratory, located at Madison, Wis., has accomplished a great deal in the investigation of wood and wood products and their application to airplane manufacture. The results of these experiments are available, also, to the Government and the public at large.

Achievements.—Since the War, the United States has acquired most of the International aircraft records, but in two important matters we still lag lamentably behind.

First, England, France and other countries have enacted national legislation and signed an International Convention, providing for the national licensing of pilots and machines, after examination and inspection and careful regulation of traffic, and also providing for the International regulation of traffic. The necessity of uniform traffic rules is as obvious in the air as it is on the high sea, and the penalty of improper control is more swift and certain and terrible. There is no adequate reason and no possible excuse for the United States to fail to regulate the air traffic within its borders and to ratify the International Airways Convention which it signed on the 13th of October, 1919, making, however, such reservations as may be needful for our safety or welfare.

The second matter in which Europe is ahead of us is that of the commercial transportation of passengers and freight and here the European preponderance is wholly due to liberal Government subsidies.

World Flight.—This was the most spectacular event that took place last year in the field of Aeronautics. On March 17, 1924, four Douglas airplanes equipped with Liberty Engines and designated as the "Douglas World Cruisers," left Santa Monica, Cal., to circumnavigate the globe. The flagship of the expedition, the Seattle, was flown by Major F. L. Martin and was wrecked in a storm off the coast of Alaska. The command of the expedition then devolved on Lieutenant Lowell H. Smith, under whose direction the remaining cruisers circled the globe, returning to the United States on September 6, 1924. The third machine, the Boston I, was wrecked while crossing the Atlantic and replaced by the Boston II, which completed the trip. The members of the flight, together with their airplanes, were as follows:

The Seattle—Major Frederick L. Martin, Sgt. Alva L. Harvey.
The Chicago—Lieut. Lowell H. Smith, Lieut. Leslie P. Arnold.
The New Orleans—Lieut. Eric H. Nelson, Lieut. John Harding, Jr.
The Boston—Lieut. Leigh Wade, Sgt. Henry H. Ogden.

In making this great flight, the first successful attempt to fly around the world in an airplane, there was a total of 28,000 miles flown, during which the three airplanes used approximately 28,000 gallons of fuel and 2,500 gallons of oil. With the exception of ordinary minor repairs, the airplanes showed their adaptability to all weather conditions and climates by returning to this country in excellent condition. One of the airplanes is to be placed on exhibition for all time in the National Museum in Washington. The success of this tremendous undertaking did much for aviation in general and for the United States in particular. First, it showed that present-day airplanes are sufficiently sturdy and dependable to accomplish long journeys over hazardous routes, and, in addition, proved the resourcefulness and capability of the Army Air Service organization and its pilots. Several other countries have attempted flights around the world but as yet none has succeeded.

Another great value of this flight lies in the fact that from it much was learned about routes over hitherto unknown courses and through conditions the effect of which on aircraft had not been known. The information thus gained may be not only of military value but undoubtedly will find valuable reference in the future establishment of commercial airways.

Records.—The records for maximum airplane speed and maximum altitude, as well as others, have for the past few years been going back and forth from the United States to France with great regularity. A new record is set up in one or the other country only to be broken a few weeks or months later by some aviator in the other. At the present time the records for maximum altitude and speed are held by the French.

Technical Development — Supercharger.—One of the most important technical developments in aeronautics in recent years is the supercharger, which, it is believed, has reached a more advanced stage in this country than in any other. This device is designed to make possible approximately the same performance of an airplane engine at high altitudes as at sea level. Since the war the Air Service Engineering Division at McCook Field, Dayton, O., has been working continuously on the project until now a supercharger has been evolved which is capable of continuous operation under the most adverse conditions. The Army Air Service has made repeated tests of this device on all types of airplanes, from the pursuit to the bombardment, with equally gratifying results in each. The supercharger was undoubtedly responsible for the previous world altitude records which were made by Lieutenant Macready and those, immediately after the war, by Major R. W. Schröder.

Large bombing planes equipped with superchargers are now able to carry greater loads to altitudes before considered impractical and the pursuit airplane is maneuverable and has a service ceiling greatly in excess of that known at the close of the war.

The value of the supercharger for military use is obvious, and it may become even of greater importance in the commercial field. Aerial navigation from the standpoint of commerce has not yet reached any definite scheme of operation. It is held by many that long distance commercial aircraft will operate at very great altitudes in order to take advantage of prevailing winds, etc. Be that as it may, the supercharger will make possible the operation of engines installed in any craft at whatever altitude may be necessary for them to take greatest advantage of natural conditions.

Compass.—One of the important problems in the development of aerial navigation has been found in the work which has been done to produce proper navigating instruments. Much of the same information is necessary relative to the movement of an airplane through the air as is necessary in the navigation of a ship at sea. However, the conditions under which the two operate are different. Since the airplane is so much faster and is operating in two planes instead of one, ordinary means to keep track of its movements are inadequate. The usual compass, for example, is inadequate on an airplane, due to the effect of the metallic parts of the machine and the rapid changes of direction of the craft. To meet this need there has been developed by the Bureau of Standards an entirely new type of compass known as the "earth inductor compass." This operates on the principle of an armature rotating in the magnetic field of the earth. With any change in the position of rotation of this armature with respect to the direction of the earth's lines of force, there is a corresponding change in the voltage generated. If a sensitive galvanometer is so arranged as to read zero for any particular position of the armature relative to these lines of force, it will show different readings corresponding to the amount of change in position.

Apparatus.—Greatly improved types of inclinometers, air speed indicators, flight indicators, bomb sights, etc., are now available for airplane use. There has just been developed a completely new type of instrument board for airplanes. Whereas the instrument board in use at the end of the war mounted a large number of circular dials for the various instruments, such as ammeters, altimeters, tachometers, etc., each one separate from the other, the new system is to combine several of these different instruments reading onto a single vertical dial. This vertical dial is ordinarily about an inch wide by four inches high, with the moving indicators traveling vertically up and down the dial. The indicators are so arranged that one may register on one side of the dial on a scale separate from another within the same instrument.

In the accessibility of the modern airplane, we find evidence of the great amount of technical work which has been done toward simplifying and making airplane repairs easier in the field. The modern airplane is so arranged that the engine and other portions of the craft are easily accessible for the mechanic who has repairs to make and also the entire power plant may be removed from the plane and a new one substituted with a minimum of time and trouble. Airplanes have been built in which it is possible to remove the entire power plant by detaching the nose of the body of the fuselage which carries it from the airplane as a unit. In such cases, any controls which may have to be disconnected are so arranged that they may be easily reconnected to similar points in the control system of the power plant which is being substituted.

Fire Protection.—Fire hazard in aircraft has been lessened by arrangement of the parts of the airplane itself so as to prevent the spread of possible fires and by precautions to prevent their occurrence. Fireproof bulkheads are built into the engine compartments, making it difficult for the fire to spread backward to the pilot's cockpit.

In order to prevent fire after a crash much time has been directed to the development of fuel containers which would not rupture upon crashing or that would be leakproof.

Parachute.—The Army Air Service has developed a type of parachute which is exceedingly efficient and, in fact, so much so, that it has been adopted by at least two other governments as service equipment of their flying personnel. The parachute is made in several models, worn in different positions on the body. However, they are all similar in that they are attached to the pilot's body with a harness before he gets into the airplane.

Photography.—The development by the Army Air Service of photographic apparatus is important. In coöperation with Major Bagley of the Engineer Corps, the Eastman Kodak Company and the Fairchild Aerial Camera Corporation, aircraft cameras have been greatly improved.

In the demonstration of the usefulness of these new cameras, much has been learned about the mapping of large areas from the air, as well as the taking of aerial photographs for reconnaissance purposes.

Photographic and experimental work has been extended to the point where great rapidity is possible in making and developing the prints.

There are several companies in the country organized for the purpose of aerial photography and mapping.

Helium.—A very important work has been done in relation to lighter-than-air traffic in reducing the production cost of helium gas to below five cents per cubic foot.

Smoke Screens.—Within the past year, the Army Air Service, in coöperation with the Chemical Warfare Service, has demonstrated the possibility of laying very effective smoke screens from aircraft and both the Navy and the Army have laid down, in a minute, in public, smoke screens or curtains a mile long and reaching over a thousand feet in height. The usefulness of such a screen in wartime is obvious.

Comparison of Lighter and Heavier than Air Types.—The Army Air Service maintains only experimental and training activities with lighter-than-air craft. Small semirigid and non-rigid airships are used for training of personnel. Free balloons and those of observation type are also used for similar work. The airship and the airplane should never come into serious competition with each other as they can be used to greatest advantage in the accomplishment of entirely different missions. The airship will carry a much greater load and transport it over much greater distances without alighting than can the airplane. On the other hand, the airship is not nearly as fast as the airplane and requires more elaborate landing facilities at terminal points. It is probable, then, that in the future the airship will find its commercial use in taking care of the "long haul" business, leaving the short, fast-covered routes to the airplane.

Helium Gas.—In connection with the operation of airships and balloons the United States in one respect, occupies an enviable position. In this country only have been found sufficiently large deposits of helium gas. At the present time, the facilities for extracting helium gas in this country are insufficient for the present needs of the Army and Navy. These will probably be improved and helium will be made available for the use of commercial concerns operating in this country. The Bureau of Mines, which has been concerned in the development of helium, has also produced repurification plants, one of which is a mobile unit mounted on railway trucks.

Science of Aeronautics.—To facilitate the study of aeronautics along scientific lines, the Government maintains the laboratories of the National Advisory Committee and those of the Army, Navy and Bureau of Standards. Likewise each year a certain number of commissioned personnel from the Government air service are sent to various academic institutions throughout the country.

Federal Legislation on Aeronautics.—Each year for the past seven or eight years bills have been introduced in Congress, but never passed, designed to regulate and govern the operation of commercial aircraft, while more than a dozen states have actually passed acts controlling aerial vehicles. Some of the national bills have attempted to establish a separate department of aeronautics within the Government, with a cabinet officer at the head; others have aimed to place the control and regulation of this new means of transportation within a new bureau of some existing department and even in existing offices. None has yet been passed. Some years ago the Department of Commerce exercised control of seaplanes while operating from the water and during the war aerial navigation was controlled by presidential proclamation.

Federal statutes will become a reality, together with the organization for their enforcement, when sufficient pressure is brought to bear upon Congress.

In Europe, where commercial aeronautics is in full swing, frontiers are close together from the flyer's point of view. A flight of one to three hours takes one over the border and into some other country. The international air convention in Europe comes, doubtless, as a result of conditions.

THE MOTOR BUS

By Carl W. Stocks

Editor of "Bus Transportation"

Extent of Service.—Four billion passengers is the estimate carried during 1925 by motor bus. This fact gives some conception of the degree to which the bus has already entered the community life of the nation. At the beginning of the year the bus industry covered 202,090 miles of route. With the 250,412 miles of steam railroad tracks and the 43,933 miles of track operated by the electric railways, it can be readily seen what an important part the bus plays in present day transportation. Rapid as the growth may seem, the opportunities of the bus industry are just beginning to be revealed.

October 1, 1925, found approximately 65,000 busses operating in the United States. Of these, about 35,000 were run by 10,000 independent bus companies, 4,500 by 250 electric railways, 1,000 by 250 hotels, 20,000 by 15,000 schools, 1,500 by sightseeing companies, 2,900 for industrial use and 250 by railroad terminal companies. The division in function indicates that the greater part of the industry is giving either common carrier or school service.

Types of Service.—Broadly speaking, the services rendered by these common carriers can be divided into two groups, the inter-city and the city. In the first of these is included services connecting two or more distinct communities. City service, of course, includes lines operated within city limits and to contiguous suburban districts. Experience has already indicated that wherever highways have been built the inter-city bus line follows, rendering service even to communities and country districts which otherwise might be without public transportation.

Vehicles.—In this connection, it is not amiss to say a few words regarding the function of the different types of busses when compared on the basis of seating capacity and weight. Of course, public attention has been attracted mostly by the development of the larger, heavier and more spectacular types. Frequently, however, the smaller 12 to 21 passenger models, on account of their lower cost of operation and lower investment, can be used where the traffic would not support the larger and more expensive heavy duty type. Again, where roads have not yet been hard surfaced, the "light duty" or small type bus is, irrespective of traffic density, the only one that can be satisfactorily operated. Any complete bus system must, however, include a number of these lighter vehicles to round out properly economical operation.

Inter-City Traffic.—In various sections of the country the inter-city bus service has developed into a veritable network of crossing and inter-crossing lines. Among the states that can be mentioned as having unusually complete systems are California, Minnesota, Ohio, North Carolina, Washington, Utah and Indiana. Although the length of these inter-city lines varies considerably, they average about fifty miles.

City Traffic.—In the city also the bus renders valuable assistance in providing service to districts where other transportation systems do not operate. The more recently developed residential areas are a good example. The bus is also proving practical as the sole public transportation system in cities with populations of 25,000 or less. Among those that might be mentioned are Gloucester, Massachusetts; Newburgh, New York; Astoria, Oregon; Everett, Washington; Middletown, Ohio; and Portsmouth, New Hampshire. In the larger cities the double-deck bus is being used. New York, Chicago, Philadelphia, Detroit, Baltimore and St. Louis all have highly organized systems operating this equipment. These are characterized by their frequent and dependable service which emphasizes comfortable mass transportation based on the idea of a seat for every passenger.

The Bus and Electric Railways.—At least 249 electric railways or their bus subsidiaries were operating on October 1, 1925, 4,437 busses as a part of unified transportation systems. This evidence of interest among electric railways definitely indicates the end of the antagonism with which they first received the bus. Some of these routes act as feeders, others as extensions beyond the rail heads, while some are completely independent and developing their own traffic. The bus industry is the result of but eleven years' development. The forerunner of the modern bus was the privately owned and operated "jitney." This vehicle made its initial appearance on the Pacific Coast and the idea spread rapidly over the country. As the early jitney services were unregulated and run in a haphazard manner, there was no way of measuring their growth. Gradually the type of vehicle used in this service changed. First came the lengthened passenger car chassis on which a 12 or 14 passenger sedan type body was mounted for inter-city service, and then the use of the ¾ and 1-ton truck chassis, with a street car type body and longitudinal seats in strictly city service. Each of these newer types became popular because of increased carrying capacity and therefore higher earning power. During this period, however, the manufacturer paid little attention to the situation.

Organization of the Industry.—It was not until the latter part of 1921 that any attempt was made to develop and manufacture a modern bus. This same period also saw the first attempt made to estimate the number of vehicles in operation. This estimate was 20,000 vehicles. Gradually the yearly increase became larger until in 1925 the estimate was a total of 65,000 busses of all classes in operation.

In the latter part of 1922 the bus was more generally accepted as an important unit in the transportation world. Activities crystallized into definite proportions, consolidations of original operating companies were effected and progress was made towards modern and safer types of vehicles. At this time also the idea of establishing and maintaining regular schedules became more firmly a tenet of the industry and the need of terminals as traffic builders better realized. This and the aggressiveness of the bus manufacturers have made the place of the bus better understood.

The Future.—As to the future growth of bus transportation, several influences are at work which will lead directly to a better establishment of the industry as a common carrier. One is the development of organizations of bus owners. Another is the increasingly noticeable trend toward consolidations of bus companies. A third is a tendency toward regulation. The manufacturer also has a part to play. It is he who must realize that, as the industry becomes better established, the bus operators will demand improvements in vehicles, which will give lower operating costs and longer life, irrespective of weight, size and carrying capacity.

Bus transportation is indeed developing on a stable foundation and those connected with the industry can well be proud of its achievements and stirred by their thoughts as to its future possibilities.

RADIO COMMUNICATION

By J. H. Dellinger

Chief, Radio Laboratory, Department of Commerce

General Progress.—The development of radio broadcasting stimulated the growth and refinement of all the earlier uses of radio, such as ship and transoceanic communication, radio aids to navigation, radio picture transmission and remote control, and amateur radio message relaying. In 1925, improvements in the instrumental facilities for these services were noteworthy, as for example the very general replacement of spark by continuous-wave apparatus. Conspicuous progress continued during 1925 in commercial radio telegraphy in competition with the ocean cables, clinching America's position of dominance in transoceanic radio. Public radio service was inaugurated with various Central American countries (Nicaragua, Honduras, Costa Rica), and with Colombia, Poland, and Sweden, thus extending the considerable radio connections previously established with Europe and South America. The construction of high power stations for similar service by American capital was begun in China and the Philippines. America approaches independence of the cables for communication with nearly every important country in the world. Progress was made on the construction of the high-power station in England required for completion of the system of radio telephone service between England and the United States; the facilities on the American side had been completed, and one-way radio telephony to England of commercial standard had been demonstrated, in 1924.

Gratifying as were the advances in all the diverse applications of radio, the outstanding progress was in broadcasting. Greeted at first as a marvel and a scientific toy, radio broadcasting was seen to have great potential effects on general enlightenment, on home life, on political activity, on musical appreciation and even on social organization. In 1925 these effects had passed from the stage of a profound hope to that of incipient reality.

Rise of Broadcasting.—The first successful broadcasting on a commercial scale, accomplished in 1921, was followed by extraordinary expansion of the use of radio. By the end of 1925, probably one-half the people in the United States had access to the radio programs through receiving apparatus. The value of radio goods manufactured during the year approximated a half billion dollars. This wholly unprecedented rise of a new service and a new industry took place almost entirely through private initiative. It received some governmental guidance through the annual National Radio Conferences called by Secretary of Commerce Herbert Hoover.

Government Regulations. — Radio is regulated in the United States under the two laws of 1912, one of them being the Ship Radio Act requiring radio transmitting apparatus on every ship carrying fifty or more persons, and the other being the Act to Regulate Radio Communication. The latter law provides for the licensing of radio stations and operators, specifies the frequencies to be used by ship stations, provides for the secrecy of private messages, and prohibits fraudulent signals and wilful interference. The law is administered, regulations are formulated, and stations are inspected, by the Department of Commerce. This law contains little that is restrictive and permits an almost unhampered growth of broadcasting. While proposed new laws have been presented in every succeeding session of Congress, there has been no legislation on radio since 1912.

The radio broadcasting system of the United States can be characterized as one of extreme freedom. Up until late 1925, anyone was free to erect a broadcasting station. In operating the station, no force other than public opinion restricts the character of the material that may be broadcast. No license or regulation other than patent rights is imposed upon the sale, purchase, and use of receiving apparatus. This is in marked contrast to the system in most other countries, where a Government license is required for the operation of a receiving set. This freedom accounts in large measure for the remarkable growth of radio broadcasting in four years from an obscure experiment to a vital force in American life.

Development of Broadcast Programs.—The earliest broadcasting was of phonograph music. Then for a year or two, the fare was largely programs from the studios of the various stations of one aspiring soloist after another, plus a heterogeneous assortment of talks. Then came the extension of pick-up lines from the broadcasting stations to theaters, hotels, athletic fields, and every place where were found fine music or important events. This improvement in the grade of material secured by the broadcasting stations culminated in 1925 in the presentation to the public through the broadcasting stations of the best fruits of current public life, of religion, education, sports, and music. Studio programs included performances by the best concert artists. Concurrent improvements in the technical phases of radio transmitting and receiving delivered all of this, to favorably situated listeners, with practical perfection. It became common for a large fraction of the population to participate, at a distance, in the excitement of great athletic contests; and the power and majesty of the art of masters of music was brought to the firesides of millions.

Radio Problems.—Despite the general improvement of the actual programs, certain problems arose along with the inevitable commercialization of broadcasting. There was a great deal of discussion over the question of regulating the character of programs. The Government consistently refused to assume the obligation of censorship, and the result is that the stations are entirely free in their choice of material. The station managements are, in point of fact, very responsive to the public reaction to their programs. This makes for high quality in the character of material and in the type of stations doing the broadcasting. The stations of higher power, greater investment of capital, and the maintenance of higher standards of equipment and program, have naturally become the most popular. The high standard and clean character of radio broadcasting compares favorably indeed with the theater, press, and other avenues of appeal to the public.

Financial Support.—One of the serious problems of the early days of broadcasting has solved itself. This is the question as to who would pay for broadcasting. With no possibility of financing the new industry by any form of assessment on the ultimate consumers, and with the artists and specialists who performed before the microphone more inclined to ask than to give financial consideration, this problem loomed large when broadcasting began. In spite of it, there has been an increase rather than a decrease in competition for the privilege of running broadcasting stations. This raises the question: What is the motive actuating the station owners to undertake and continue such large investments, the operation of a first-class station costing not less than $100,000 a year. This can be discerned by examining the character of ownerships of the stations. Approximately one half of them, in 1925, were owned and operated by manufacturers of or dealers in radio sets and others who profit by the sale of radio material. The other half were owned by educational, religious, and Governmental institutions and various commercial and semi-commercial organizations, whose interest lies in influencing the public. By and large, both classes could be said to conduct their stations as one form or another of advertising.

Advertising Influence. — Advertising is more highly developed in the United States than in other countries, and it has been found that radio broadcasting is a very effective and profitable form of advertising.

The second class of broadcasters were becoming proportionately more important than the first. The second class began to be modified in one respect, that is, by the rental of broadcasting service to parties who desire to pay for the privilege of furnishing the programs. These interests profit through the advertising gained through the mention of their names in connnection with the program. The advertising motive thus began to support broadcasting, not directly through ownership but through use of the broadcasting stations. This practice, however, brought to the front a serious question whether the commercialization of radio would not impair its effectiveness. Listeners began to be uneasy over the too rude intrusion of soap, bonbons, and typewriters in the midst of otherwise beautiful programs.

Platform of Principles on Publicity.—The importance of the question was recognized in the adoption of the following resolutions by the Fourth National Radio Conference in November:

"WHEREAS the excellence and public service value of radio programs is increased by the support of those seeking appropriate publicity.

"AND WHEREAS the use of inappropriate publicity methods meets with the hearty disfavor of the listening public.

"AND WHEREAS this public disfavor is fatal to the purpose of those seeking publicity and good will, as well as detrimental to the interest of the broadcaster and all branches of the radio industry.

"RESOLVED that it is the sense of this conference that the best interests of the listening public, of the radio industry, and of the broadcaster are all served by that form of broadcasting which provides a meritorious program of entertainment and educational nature and which limits itself to the building of good will for the sponsor of the program whether he be the owner of the station or a subscriber utilizing its facilities.

"RESOLVED that the Conference deprecates the use of radio broadcasting for direct sales effort, and any form of special pleading for the broadcaster or his products; which forms are entirely appropriate when printed or through direct advertising mediums.

"Resolved that the Conference concurs in the suggestion of the Secretary of Commerce that the problems of radio publicity should be solved by the industry itself and not by Government compulsion or by legislation.

"And Resolved that the Conference urges upon all owners of radio broadcasting stations the importance of safeguarding their programs against the intrusion of that publicity which is objectionable to the listener and consequently detrimental to others in the industry, as well as to the reputation of the individual broadcasting station."

Use of Copyrighted Music.—Another aspect of commercialism in the radio programs which caused serious difficulty was the question of use of copyrighted music. The listening public sometimes became aware of this through the occasional announcement that a performance had to be interrupted because of a demand for exorbitant royalties from the holder of copyright on some musical selection. These demands seldom came from the composer or author himself. The situation was essentially a contest between the broadcasters and the Society of Composers, Authors, and Publishers, an organization which controlled the copyrights on a large proportion of the popular music. The battle was still in progress at the end of the year.

At the Fourth National Radio Conference it was agreed by all interests that the owners of copyrights were entitled to reasonable compensation for the use of their copyrights, and the representatives of the broadcasting interests indicated a complete willingness to pay a reasonable charge for copyrighted numbers used by them. It appeared, however, that the parties were not able to agree upon the terms and conditions of use of copyrights.

Platform of Principles on Musical Copyright.—The Conference Committee on Copyright Relations to Broadcasting reached the conclusion that no good purpose would be served by undertaking to make a recommendation upon these disputed matters. The Committee, however, considered the principles which should control in the solution of this problem, and its conclusions are embodied in the Resolutions presented to the Conference, a copy of which is shown below. Attention is directed to the fact that this Resolution is applicable in terms only to musical compositions. The Committee did not undertake either in its deliberations or its recommendations to deal with copyrights of literary or dramatic productions nor of press matter.

"Whereas, there can be no continuation of broadcasting unless musical compositions are made available to broadcasters upon a fair, equitable and permanent basis, and

"Whereas, an insistent demand from the public requires that music be made the principal part of broadcast entertainment, and

"Whereas, practically all of this music is held by copyright proprietors and is not available to broadcasters except on prohibitive and unstable terms, and

"Whereas, the broadcasters recognize the right of the copyright proprietors to compensation for the use of their compositions and are willing to pay a fair and equitable maximum fee for each broadcast rendition of each copyright musical number, and

"Whereas, broadcasters believe that copyright owners should have the sole, complete and entire right to withhold their property from all broadcasting if they so desire; but that if a copyrighted number is released by the owner thereof to one or more broadcasters, then such number shall become available to all broadcasters, and

"Whereas, the present conditions threaten the entire broadcasting structure and the continuation and permanence of broadcasting depends upon the solution of this problem, and

"Whereas, all attempted solutions through negotiation between the parties have proved unavailing; now therefore

"Be It Resolved, that it is the sense of this Conference that the only possible solution lies in the enactment of suitable legislation based upon the above principles, and it is the recommendation of this Conference to the Secretary of Commerce that such legislation be suggested to Congress."

Dilemma of Too Much Broadcasting.—The very success and popularity of broadcasting gives rise to its principal difficulty or problem, which came to a head in 1925. The difficulty arises fundamentally because of the interference of one radio wave with another. All the radio signals are conveyed along a single track, the ether, and very skilful dispatching is required to avoid collisions. Every conceivable interest wanted to broadcast, because radio was found to be an efficient vehicle of publicity. It would not have been so bad if everyone had wanted to start a newspaper, because the printing of one newspaper does not get in the way of the printing of another; but in radio only so many can operate at one time. This physical condition was not taken into account by many persons and groups who wanted to broadcast and who should have been at least as willing to hold back from erecting radio stations as from starting newspapers. Not everyone who has a message for the public starts a newspaper; he usually uses for his purpose the newspapers already existing.

Antagonistic Frequencies.—The basic reason that the number of broadcasting channels is limited is that the frequencies of broadcasting stations are spaced 10 kilocycles apart. It has been found in practice that this is the minimum separation which permits satisfactory reception without interference. Rules for still greater frequency separation at certain distances are also observed. There are 95 channels or frequencies available, 10 kilocycles apart, in the frequency range used for broadcasting. Since there were 578 stations in 1925, not every station could have an exclusive frequency but most of them had to share with one or more other stations. This multiple assignment of frequencies required that the stations alternate in the use of the frequencies, as for instance, by transmitting on alternate nights. This was generally recognized as undesirable. In spite of this, the erection of stations and the applications for broadcasting licenses continued unabated. By November, 1925, there were pending before the Department of Commerce 175 applications for licenses to operate new broadcasting stations. As all the channels for broadcasting were already completely filled, the Department could see no way of complying with these applications for licenses.

Secretary Hoover's Diagnosis.—This situation was made the chief theme of the Fourth National Radio Conference, already referred to, which was held November 9, 10, and 11 in Washington. The Conference was attended by about 500 representatives of the radio industry, broadcasters, manufacturers, listeners, the press, etc. The discussions at the Conference brought out clearly that broadcasting would be ruined unless a severe check were put on the increase of the number of stations. This problem was put by Secretary Hoover as follows in the speech with which he opened the Conference.

"It is a simple physical fact that we have no more channels. It is not possible to furnish them under the present state of technical development. It takes no argument to demonstrate that 89 wave lengths (and no more are available) cannot be made to serve innumerable stations, no matter how ingenious we may be in arranging time divisions and geographical separations. It is not a question of what we would like to do but what we must do.

"One alternative, which would only partly solve the problem, would be to increase the number of stations by further dividing the time of the present stations down to one or two days a week or one or two hours a day. From the listener's viewpoint, and that is the only one to be considered, he would get a much degenerated service if we were to do that. . . . A half dozen stations in any community, operating full time, will give as much service in quantity and a far better service in quality than eighteen, each on one-third time.

"As the art progresses the capital investment in a good station has risen to upwards of $150,000, and the cost of operation has risen to as much as $100,000 per annum, and frequently even more. The costs are in large part the same whether the station works one day in a week or seven. If we impose more division of time than at present we shall drive the best stations out of action and the public will be more poorly served. . . .

"It has been suggested that the remedy lies in widening the broadcasting band, thus permitting more channels and making it possible to provide for more stations. The vast majority of receiving sets in the country will not cover a wide band. Nor could we extend it without invading the field assigned to the amateurs, of whom there are thousands and to whose constant experimentation radio development is so greatly indebted."

Secretary Hoover on Freedom of the Air.—"All these things bring us face to face with the problem which we have all along dreaded—we must now decide the issue of whether we shall have more stations in conflicting localities until new discoveries in the art solve the problem.

"We hear a great deal about the freedom of the air. But there are two parties to freedom of the air, and to freedom of speech for that matter. There is the speech maker and the listener. Certainly in radio I believe in freedom for the listener. He has much less option upon what he can reject, for the other fellow is occupying his receiving set. The listener's only option is to abandon his right to use his receiver. . . .

"We do not get much freedom of speech if 50 people speak at the same place at the same time, nor is there any freedom in a right to come into my sitting room to make a speech whether I like it or not. . . . In any event we can surely agree that no one can raise a cry of deprivation of free speech if he is compelled to prove that there is something more than naked commercial selfishness in his purpose.

"The ether is a public medium, and its use must be for public benefit. The use of a radio channel is justified only if there is public benefit. The dominant element for consideration in the radio field is, and always will be, the great body of the listening public, millions in number, countrywide in distribution. . . .

"There have been few developments in industrial history to equal the speed and efficiency with which genius and capital have joined to meet radio needs. The great majority of station owners today recognize the burden of service and gladly assume it. Whatever other motive may exist for broadcasting, the pleasing of the listeners is always the primary purpose."

Conference Resolutions.—That the principles that the number of stations must be limited, and that the public interest must be the basis of granting a broadcasting license, were set forth in the following resolutions of the Conference:

"Resolved, that further division of time among stations is not in the interest of public service and that the Department of Commerce should decline to grant any more licenses until the present number of broadcasting stations shall have been substantially reduced.

"Resolved, that the band of frequencies now assigned to broadcasting is overcrowded, causing serious interference. Therefore the Committee recommends, in the interest of public service, that no new stations be licensed until, through discontinuance, the number of stations is reduced and until it shall be in the interest of public service to add new stations.

"Resolved, that public interest as represented by service to the listener shall be the basis for the broadcasting privilege."

The Department of Commerce began putting these principles into effect immediately after the Conference, deleting a number of stations and licensing no new ones.

The adoption of these principles will inevitably bring about a great increase of the practice of renting the time of broadcasting stations to parties who wish to furnish the programs in order to secure advertising thereby. And, as more and more interests conclude that they can secure the results they desire through rental of the services of existing high-class broadcasting stations rather than through station ownership, the desire to own stations will become less fervent.

Technical Advances in Broadcasting.—The interconnection of stations so as to provide for simultaneous broadcasting of the same program by several stations is one of the most important developments. It has made possible a wide extension in the knowledge of national events; it makes the talent of the great cities available to everyone. The interconnection of a chain of stations has become a matter of regular daily procedure. In a few cases there was nation-wide simultaneous broadcasting of national events by 20 to 30 stations. This interconnection was in general accomplished through the use of long-distance wire telephone lines. In a few stations it was accomplished through the use of radio rebroadcasting, the program being picked up by the reproducing station at a frequency either above or below the broadcasting frequencies, removed by a factor somewhat greater than 2 from the limit of the broadcast band.

The effort to make a single program simultaneously available to larger and larger audiences was also being furthered by the use of higher and higher power. About 30 stations increased their power within the year from approximately ½ to 5 kilowatts. Three stations increased to a power of 10 to 50 kilowatts. This extension of the scope of radio broadcasting foreshadowed the possibility of world-wide as well as nation-wide broadcasting. Besides extending the distance of reception, the use of greater power delivered the broadcast programs to every locality relatively freer from static and every other kind of either atmosphere or electrical interference.

Interference.—Steady progress continued against the two great classes of interference, natural and man-made. As to the natural interference, it has come to be recognized that there will always be a certain residuum of atmospheric disturbances which will necessarily limit the distance from any broadcasting station at which reliable and satisfactory reception will be possible. The various kinds of man-made interference, on the other hand, are curable and are of local character; more and more localities were freed from the various types of this pest, particularly through the efforts of the electric power companies in following up complaints and tracing down defective electrical apparatus.

Nowhere has the interference problem been more acute than in radio broadcasting. When broadcasting began, it was all done on a single frequency or wave length. The resulting interference soon made this impossible, and the service has evolved until at present broadcasting has exclusive use of the frequency band from 550 to 1500 kilocycles per second (545 to 200 meters). The small separation of 10 kilocycles between broadcasting station frequencies requires that the frequencies be maintained with very great constancy. This requirement has been satisfactorily kept in view by the Government and by the transmitting stations themselves. Whistling interference produced by the heterodyne action between two station frequencies, while common two years ago, is now comparatively rare. Coincident with this advance there has been improvement in the ability of receiving apparatus to receive a desired station and exclude others. Many listeners continued as greatly interested in receiving from distant stations as from nearby ones; and this gave a market to very selective receiving sets.

Substantial improvement has been made also in radio receiving apparatus in the ability to deliver sound of high quality. Electron tubes of greater power and less distortion, together with improvements in loud speakers, transformers, and general design, permitted the production of receiving sets which gave substantially perfect quality, with volume as great as it had been in the original performance.

Fading.—Scientific and engineering laboratories devoted a great deal of study to fading, or the irregular fluctuation of received signal strength which is noticed when listening to programs from distances of 50 miles or more. While much was learned of the facts, this limitation on radio was not conquered. The only answer at the present time is that perfection can not be experienced in reception at such distances, and so the effective service area of a station is limited to a small area around it. In order to extend this service area, in European countries some of the broadcasting is done on lower frequencies (longer waves), since they do not fade so much. In England, for instance, a 30-kilowatt station in the center of the country, on a frequency of 190-kilocycles (1600 meters) was built to deliver programs to owners of crystal detector receiving sets over most of England. The use of multiple antennas was tried in America, and this and other expedients to reduce fading continue under investigation. Some noteworthy contributions were made during the year to the explanation of the vagaries of radio wave transmission.

Spectrum of Radio Frequencies.—The basic means of controlling traffic in the ether, so as to enable the several kinds of radio service to proceed simultaneously without destructive interference, is the allocation of certain regions or bands of the frequency spectrum to those services. This allocation has undergone a certain evolution in practice and in the decisions of the National Radio Conferences. In the 1925 Conference consideration was given to extending the band devoted to broadcasting. It was contended that this would permit the relief to some degree of the condition of overcrowding. Nevertheless, "no additional channels were found available for broadcasting except by sacrifice of the major wave band used by the amateurs; and careful analysis showed that even if this entire band were to be transferred to broadcasting the contribution toward the reduction of interference would be relatively slight. Furthermore, any such change in broadcasting channels would inevitably render at least partially obsolete the millions of broadcasting receiving sets now in use. No benefit proportionate to the certain damage could be found, and consequently the broadcasting wave band was not changed."

The absolute preëmption of the frequency band from 550 to 1500 kilocycles by broadcasting made it necessary that ship radio communication relinquish the use of certain frequencies formerly used in this band. As a result ship traffic was removed to frequencies between 120 and 190 and between 285 and 500 kilocycles. The allocation of frequencies, as made by the Fourth National Radio Conference, is given in the following table. Frequencies below 95 kilocycles are used for point-to-point land and transoceanic radio communication.

TABLE OF ALLOCATION OF FREQUENCIES

kc	m	Type of Transmission	Service	Remarks
95-120	3,156-2,499	CW and ICW	Government only.	
120-153	2,499-1960	CW and ICW	Marine and aircraft only.	
125	2,399	CW	Government.	Non-exclusive.
153-165	1,960-1,817	CW and ICW	Point to point, marine and aircraft only.	
155	1,934	CW and ICW	Government.	Non-exclusive.
165-190	1,817-1,578	CW and ICW	Point to point and marine only.	
175	1,713	CW and ICW	Government.	Non-exclusive (ice patrol, broadcast, etc.).
190-230	1,578-1,304	CW and ICW	Government only.	
213-235	1,304-1.276	CW and ICW	University and college, experimental only.	
235-285	1,276-1,052	Phone	Marine only.	

TABLE OF ALLOCATION OF FREQUENCIES (*continued*)

kc	m	Type of Transmission	Service	Remarks
245	1,224	CW and ICW	Government.	Non-exclusive.
275	1,090	CW and ICW	Government.	Non-exclusive.
285-500	1,052-600	....	Marine, coastal, and government only.	
300	1,000	CW and ICW	Beacons only.	
315	952	CW and ICW	Government only.	
343	874	CW and ICW	Marine only.	
375	800	CW and ICW	Compass only.	
410	731	CW, ICW, spark	Marine only.	
425	706	CW, ICW, spark	Marine only.	
445	674	CW and ICW	Government.	Non-exclusive.
454	660	CW, ICW, spark	Marine only.	
500	600	CW, ICW, spark, phone	Calling and distress, and messages relating thereto, only.	
500-550	600-545	CW, ICW, phone	Aircraft and fixed safety of life sta.	Non-exclusive.
550-1,500	545-200	Phone	Broadcasting only.	
1,500-2,000	200-150	CW, ICW, phone	Amateur only.	
2,000-2,250	150-133	....	Point to point.	Non-exclusive.
2,250-2,300	133-130	....	Aircraft only.	
2,300-2,750	130-109	....	Mobile and government mobile only.	
2,750-2,850	109-105	....	Relay broadcasting only.	
2,850-3,500	105-85.7	....	Public toll service, government mobile, and point to point communications by electric power supply utilities and point to point and multiple address message service by press organizations, only.	
3,500-4,000	85.7-75.0	....	Amateur, army mobile, naval aircraft and naval vessels working aircraft, only.	
4,000-4,525	75.0-66.3	....	Public toll service, mobile, government point to point, and point to point public utilities.	Non-exclusive.
4,525-5,000	66.3-60.0	....	Relay broadcasting only.

Advances in Radio Engineering.—A conspicuous recent development in radio is the conquest of the new domain of very high frequencies (short waves). Even the existence of the vast range of frequencies above 2,000 kilocycles (below 150 meters) was hardly suspected, and certainly was generally forgotten, until 1924. One curious reason for the subordination of this range of frequencies has been the erroneous use of wave length in meters as an expression of radio frequencies. Radio engineering actually deals with currents which have a certain frequency. The wave length of the wave as it travels along in space can be calculated from the frequency, but it is a derived and an artificial concept. Frequencies up to 20,000 kilocycles came into extensive use in 1925. Actual radio services were conducted in this region by transoceanic communication companies, military services, broadcasters, amateurs; in short, every important radio interest began operations between 2,000 and 20,000 kilocycles. The applications to broadcasting were largely limited to the relaying of radio programs from one station to others which in turn broadcast at their normal frequencies. Even higher frequencies were used in experiments, but there is every likelihood that in the development of frequencies above 20,000 kilocycles directive transmission will predominate and the problems will be of a distinctly different character. Through the high frequencies a solution of a problem which had been regarded as insoluble, that of finding more communication channels, was reached. As shown in the frequency allocation table above, frequency bands approximately 10% wide in the frequencies above 2000 kilocycles were assigned to the different services, land point-to-point, aircraft, ship, relay broodcasting, public toll service, amateur, and Government. An important principle was followed in the assignment, viz., each service was protected from possible harmonic interference from stations of other services by placing the several frequency bands of any given service on its own harmonics.

One of the principal means of overcoming interference between the transmissions from simultaneously operating radio stations is the increase of selectivity or narrowing of the band of frequency which each station uses. Progress in this direction was made in all the various types of transmissions, as for example, through the use of filtering devices for radio telephony and coupled circuits in arc and spark apparatus. The principal advance, however, was the increasing adoption of continuous-wave transmission for radio telegraphy. There was also the advent of strictly constant frequency systems. A striking means of accomplishing this was furnished by the piezo oscillator. A new radio communication system of the utmost selectivity and precision was made available by this new device, and services which require the operation of a large number of transmitting stations spaced as closely together as possible in frequency and taking full advantage of CW transmission found this a great improvement. The piezo oscillator uses a plate of quartz vibrating at a radio frequency and simultaneously generating a current; it serves as a remarkably constant standard of frequency.

Improvement in Engineering.—The year in radio was characterized not so much by the invention of devices and methods as the perfection of them. Broadly speaking, radio engineering took definite form and became the tool by which progress in radio is being and will be wrought. There was substantial progress all along the line of radio engineering. Thus, in the development of new and improved radio communication methods or systems, there was great extension of the available frequency range, marked improvements in directive radio transmission, advances in the perfection of selective radio systems, and engineering development of line-radio or carrier-current communication. Among radio devices and applications of radio there was outstanding progress on radio beacons, on the use of radio for aircraft navigation, on direction finders, on radio picture transmission, and the achievement of radio motion pictures in very elementary form. In the field of research and study of the problems of radio, there was important progress in radio measurements, in standardization of apparatus, in the study and mitigation of the vagaries of wave propagation and atmospheric disturbances, and in the wide reaches of the interference problem. Increase of knowledge and of practical applications characterized all phases of radio.

EXPRESS BUSINESS

By H. L. Caverly

Professor at the University of Michigan

American Railway Express Company.—The express business of the United States is not conducted directly by the railroads, as it is in most foreign countries, but has always been handled through the medium of separately organized express corporations. Since July, 1918, the business has been predominantly in the hands of the American Railway Express Company, organized at the request of the then Director-General of Railroads to take over the business of the four leading companies. A permanent consolidation was approved in December, 1920, by the Interstate Commerce Commission, and the remaining lesser companies included. The American Company executed standard contracts with the railways for the carriage of express in September, 1920, under which the payment for express privileges is so adjusted as to assure the company, in effect, a return of 6% on its investment and a limited participation in profits above this amount. During the first half of the year 1925 the company was operating over an average of 258,236 miles of transportation lines, chiefly of railway carriers.

Transactions.—According to official figures of the Interstate Commerce Commission the aggregate gross receipts from operation during 1924 were $290,637,167, as compared with $313,179,966 for 1923, a decrease of about 7 per cent. Payment for the express privilege likewise decreased to $139,281,416 from the figure of the preceding year, $155,736,205, leaving a total operating revenue of $150,639,783 in 1924, in comparison with $157,443,761 in 1923. Operating expenses of the company during the two periods were: $147,446,609 in 1924; $154,446,244 in 1923.

As a net result the operating income of the company (net operating revenue adjusted for express taxes and uncollectible items) increased during this period—from $883,871 in 1923 to $1,045,468. The net income of the company, including in addition to the above, receipts from other than express services, was $2,503,726 in 1924, as compared with $2,685,161 in 1923.

Preliminary returns for the first six months of the year 1925 indicate a further slight falling off in revenues. Gross receipts for the six months ending June 30, 1925, were $140,906,735 as compared with $143,183,710 for the corresponding period in 1924. The net income for the same period in 1925 was $1,030,072, a decline from $1,138,680 in the first half of 1924. (A more complete exhibit of the financial operations of the company will be found in the statistical section at the end of this division.)

Southeastern Express Co.—In addition to the American Railway Express company, the Southeastern Express company was organized in 1921. This company operates over 10,000 miles of line of the Southern Railway and the Mobile and Ohio, its organization arising out of a disagreement between these roads and the American company. The gross business of the Southeastern company in 1924 was $8,039,397. Operating expenses amounted to $4,214,665. The balance was divided between the carriers and the company, the latter receiving, under its contract, a guaranteed dividend of $70,000 or 7 per cent. on its capitalization.

Rates.—On March 1, 1925, a new schedule of express rates went into effect. The American Express Company had petitioned for increased rates in 1922 and a comprehensive investigation of the express rate structure was undertaken by the Interstate Commerce Commission. The result, in general, was an order, issued in May, 1924, raising the level of rates in Zone 1 (the New England states and New York-Chicago trunk-line territory) and lowering rates in the remainder of the country, together with a readjustment of the rate zone boundaries. The intention of the Commission was to readjust rates more in accord with transportation costs, rather than to alter the general level. Application of the new schedule was delayed by litigation until this year.

TELEGRAPHS AND TELEPHONES

By Harcourt L. Caverly

Professor at the University of Michigan

TELEGRAPHS

Transactions.—The only complete data for the telegraph industry in the United States are those reported by the U. S. Census Bureau at intervals of five years, the latest figures being for the year 1922. In that year 19 land telegraph systems were in operation in the United States, maintaining 27,253 telegraph offices, as compared with 21 systems and 28,865 offices in 1917. The decreases indicate gradual unification of the industry as the volume of business is increasing steadily. The magnitude and growth of the industry are shown by the number of messages handled: 185,841,267 in 1922, as compared with 155,263,206 in 1917. The total investment of the industry in plant and equipment increased during the period from $163,487,637 to $254,029,933; the number of employees engaged from 49,608 to 64,902; and the wages paid from $37,879,560 to $71,491,743. The total gross revenue of the several systems in 1922 was $130,538,660; operating expenses amounted (after deduction of interest and to $102,010,773; and net income taxes) was $15,674,759. The corresponding figures for 1917 were: Gross revenue $92,954,370; Expenses $66,959,295; and Net Income $12,125,400.

Western Union.—While data after 1922 are not available for the industry as a whole, the financial operations of the Western Union Telegraph Company, which largely controls the business in this country, may be cited. The gross operating revenue of the company in 1924 was $112,861,555, operating expenses including taxes $99,581,556, and net operating revenue $13,279,999. The net income of the company (including non-operating revenue and deducting fixed charges) was slightly greater,—$13,336,682. The property investment of the company was $231,514,005. Preliminary figures for the year 1925 indicate a substantial increase in business. For the nine months ending September 30 gross revenue amounted to $94,141,130 and net income to $11,545,490; as compared with $84,861,418 and $9,511,355 respectively for the corresponding period in 1924.

Mackay Companies.—The chief competitor of the Western Union Telegraph Company is the Mackay Companies, a voluntary association of telegraph companies, which controls the Commercial Telegraph Cable Company and through it the Postal Telegraph system. The statements of the Mackay Companies show income from investments in telegraph companies of $4,787,286 in 1924, operating expenses of $173,955, and a net income of $4,613,331, the bulk of which was paid out in dividends. The policy of the association is to permit the accumulation of profits in the treasuries of its subsidiaries, except for an amount sufficient to meet its own dividend requirements.

Cables.—The telegraph industry is exhibiting at the present time much interest in the technical development of transoceanic cables. The plant investment of American companies in cables in 1922 was $72,631,927, representing 52,430 nautical miles of cable (U. S. Census Bureau). In

1924 the Western Union Company completed a "high speed" cable from New York to the Azores, capable of transmitting over 1,500 letters a minute. The company announced in 1925 that a similar cable across the North Atlantic to England was under construction, to be completed in 1926.

TELEPHONES

Business.—As in the case of the telegraph industry, the latest complete figures for the telephone business of the United States are those reported by the U. S. Census Bureau for 1922, with comparative figures for 1917. In 1922 there were 1,323 telephone systems in the United States reporting annual incomes of $10,000 or over. This compares with $2,200 in 1917 and indicates a policy of steady unification. The number of telephones in use in the two years increased from $9,953,710 in 1917 to $12,295,234 in 1922, a growth of about 19 per cent., and the estimated number of messages has reached tremendous heights, 19.8 billion in the former year, 21.9 billion in the latter. The industry employed, in 1922, 290,333 persons with a wage expenditure of $341,537,822, in comparison with 244,490 employees in 1917 and wages of $169,655,066. During the same period the investment of the industry in plant and equipment grew from $1,435,912,142 to $2,129,773,760.

The total gross revenues of the companies were $656,823,908 in 1922, as compared with $372,501,800 in 1917, an increase of about 76 per cent., which, of course, reflects the general increase in telephone rates as well as increasing business. Operating expenses (including fixed charges and taxes) underwent a similar increase from $313,103,060 in 1917 to $560,159,965 in 1922. The net income of the business increased from $59,398,740 to $96,663,943.

Bell Companies.—Figures later than 1922 are not available for the industry as a whole, but the consolidated statements of the Bell Telephone companies (subsidiaries of the American Telephone and Telegraph Company) are indicative of the development of the business. The gross earnings of the Bell companies for 1924 (excluding duplications) were $677,902,813, as compared with $623,110,988 in 1923 and $564,028,691 in 1922. The net income after deduction of fixed charges was $107,245,548 in 1924, as compared with $99,624,472 and $86,622,752 in 1923 and 1922 respectively. These figures reflect the steady expansion of the industry. Better indices of growth are found perhaps in the increase from 1922 to 1924 in number of employees, from 243,053 to 279,659, in number of telephone stations from 14,050,565 to 15,906,550, and in mileage of telephone line from 30,616,522 to 39,893,619.

American Telephone and Telegraph Co.—Preliminary statements of this controlling corporation for 1925 indicate an even more rapid growth of business this year. The total earnings of the company for the first nine months of the year were $132,271,232, as compared with $111,505,361 for the corresponding period in 1924. During the first half of the year the company made a net addition to telephone plant in the United States of $125,000,000. The completion of a through telephone cable from New York to Chicago, 861 miles in length and said to be the longest yet constructed, was a notable technical development of the year. (Further data for the telegraph and telephone industries may be found in the statistical section at the end of this division.)

AUTOMOBILE TRAFFIC AND REGULATION

By Harcourt L. Caverly
Professor at the University of Michigan

Progress.—The growing importance of the motor vehicle as a means of transport and the problem of its proper adjustment to older transportation agencies have but recently been clearly recognized. An index of the significance and rapid growth of highway transportation in general may be found in the data of automobile production and registration. According to figures of the U. S. Census Bureau, 3,638,388 automobiles were manufactured in the United States and Canada in 1924, as compared with 4,093,939 in 1923 and 2,638,562 in 1922. This was a decline of 11 per cent. from 1923 production, but an increase of 38 per cent. over 1922. The total production for 1924 included 3,263,307 passenger cars and 376,081 trucks. Total registrations of motor vehicles in the United States in 1924 amounted to 17,591,981, as compared with 15,092,177 in 1923, 12,238,375 in 1922, and 1,711,339 in 1914. The number of vehicles registered has increased approximately ten times in ten years. On the basis of advance estimates of a production of about 4,100,000 in 1925, total registrations for this year should be well over 20,000,000. In all about four-fifths of the world's motor cars are in the United States.

Competition.—It is generally conceded that the larger part of automobile travel represents a net addition to the volume of transportation, rather than a deduction from the business of other carriers. But the competitive phase of the situation is of increasing significance. Aside from private use the motor vehicle is establishing itself as a common carrier, competing with the electric railway through the development of motor-bus lines and with the railroad through the highway transport of freight. [See Section J. Motor Bus Service.] During 1925 a number of railway systems, including the Pennsylvania and New York Central, were experimenting with the use of the motor truck to replace local freight train service. Many of the larger terminals are developing motor truck service to replace interterminal switching or effect store-door delivery of freight. During the year the Boston and Maine Railroad announced that it contemplated abandonment of about 1,000 miles of branch line in favor of truck operation. The difficulties of adjusting the two agencies can be overstressed, however, since the truck competes, where at all, chiefly in the field of short-haul traffic, which is not relatively profitable for the railway. In October, 1925, the Bureau of Public Roads published an analysis of the causes of abandonment of railway mileage since 1920. Of the total abandoned mileage but 4.3 per cent. was attributed to motor competition, exhaustion of natural resources (57.8 per cent.), and competition of other railways (29.3 per cent.) being cited as the chief causes for the abandonment.

Regulation of Traffic.—Two problems of automotive regulation may be distinguished: the regulation of highway traffic and the regulation of motor vehicle common carriers. Regulation of the first type—licensing of drivers, restrictions on size, weight, and speed of vehicles, and establishment of traffic rules—has been marked by decided lack of uniformity. In December, 1924, the first National Conference on Street and Highway Safety, called by Secretary of Commerce Hoover, recommended a uniform code of highway traffic regulations and stressed the desirability of state rather than local control. A Joint Board of Interstate Highways was appointed by the Secretary of Agriculture in March, 1925, to designate interstate highways and provide for uniform markings. In November, 1925, a model ordinance to secure uniform municipal traffic regulation was approved by a state-wide conference in Michigan and its universal adoption by municipalities of the state urged. In various ways, therefore, the year has furthered the movement toward greater uniformity in traffic control.

Machinery of Regulation.—Regulation of the motor vehicle as a common carrier has been definitely undertaken in some 38 states, although there is much variance in the methods and extent of such regulation. In many of these states regulatory power is vested in a state board, usually the public utility commission. In a number of the states, however, local authorities are still permitted wide powers of control. The two typical restrictions placed on the business are the requirement of a "certificate of public convenience and necessity" precedent to operation, and the filing of an indemnity bond or the carrying of public liability insurance to guarantee financial responsibility.

Interstate Traffic.—In March, 1925, in three decisions the Supreme Court of the United States denied the right of the states to regulate interstate highway carriers, though no Federal regulation of such carriers has been instituted. In the absence of Federal legislation this portion of the business will remain without regulation. The National Association of Railroad and Utility Commissioners has taken up the question and in November, 1925, approved a bill to be presented at the present Congress. Their measure provides for federal regulation of interstate motor commerce with the use of the state commissions as the agencies of administration.

LEGISLATION AND COURT DECISIONS ON TRANSPORTATION

By Harcourt L. Caverly
Professor at the University of Michigan

Federal Legislation.—The only important enactment of the second session of the Sixty-eighth Congress bearing on transportation was the Hoch-Smith Resolution, a joint resolution approved January 30, 1925. This resolution directed the Interstate Commerce Commission to make a general investigation of the rate structures of common carriers, to determine to what extent existing rate structures may be unjust and discriminatory, and to adjust rates on agricultural products to promote freer movement of such products, to the greatest degree "compatable with maintenance of adequate transportation service." Hearings on the subject were begun by the Commission in September, 1925, in conjunction with hearings on a request of the Western roads for a 5 per cent. rate advance. These hearings are still in progress.

Court Decisions.—The following are among the more important decisions affecting transportation agencies made by the Supreme Court of the United States during the October Term, 1924.

(1) **Employee Representation Cases** (Federation No. 90 v. Penn. RR. Co., Brotherhood of Ry. and SS. Clerks, etc. v. Penn. RR. Co. U. S. Supreme Court. March 2, 1925).—These cases continue the dispute between the Pennsylvania Railroad and its employees regarding the selection of employee representatives for purposes of conference in respect to wages, etc. The road had sought unsuccessfully to enjoin the U. S. Railroad Labor Board from prescribing such methods of selection, authorizing unions to act as representatives, and publishing its findings. 261 U.S. 73 (1923). Although deciding in favor of the Board on these issues, the court held that decisions of the Board had no binding force against the parties. In the present cases the unions sought to enjoin the road from conduct of an alleged conspiracy to deprive them of rights, granted them under the Transportation Act and the decisions of the Labor Board, to act as representatives of the employees. The court in deciding against the unions reaffirmed the conclusion that the Labor Board has no power under the Transportation Act to enforce its decisions, that the Act created no rights in either employer or employee, and consequently that the road was within its legal rights in refusing to follow the order of the Board to deal with the unions, and was not subject to be enjoined.

(2) **Interstate Motor Transport Cases** (Mich. Public Utilities Comm. v. Duke. U. S. Supreme Court, January 12, 1925, Buck v. Kuykendall; Bush v. Maloy, U. S. Supreme Court, March 3, 1925.)—These decisions had the effect of restricting the authority of the states and their commissions in the regulation of motor common carriers to those engaged in intra-

state commerce. It was held that acts requiring a state permit or certificate precedent to the use of highways by motor common carriers were unconstitutional, if applied to carriers engaged exclusively in interstate commerce. Further, in the Michigan case, a statute imposing public utility obligations on a private carrier, operating under individual contracts, was held unconstitutional.

(3) **Delaware and Hudson Valuation Case** (U. S. Supreme Court, January 5, 1925.)—In this decision the Supreme Court upheld a tentative valuation of railroad property by the Interstate Commerce Commission to the extent of denying judicial interposition pending consideration by the Commission of the railroad's protests. The Commission must be given opportunity to take final action, since the tentative valuation is held to be an *ex parte* appraisement without probative effect.

(4) **Interurban Railway Cases** (U. S. Supreme Court, January 5, 1925.) —These cases upheld the power of the Interstate Commerce Commission to regulate interstate interurban electric railways and affirmed the Commission's power to order an increase in their intrastate rates, where such rates had been found to discriminate improperly against interstate commerce.

(5) **Statute of Limitation Decisions.**—In Danzer v. Gulf and Ship Island Railroad Co. (U. S. Supreme Court, June 8, 1925) the clause of the Transportation Act, which rules that the period of governmental operation of railroads shall not be counted in computing the two years allowed under the Interstate Commerce Act for filing damage claims, is not to be viewed as reviving claims which had lapsed prior to the passage of the Transportation Act. In Fullerton-Krueger Lumber Co. v. North. Pacific RR. Co. the same court applied a similar rule where the statute of limitations involved was contained in a state statute.

(6) **Abandonment of Lines** (Fort Smith Light and Traction Co. v. Bourland, U. S. Supreme Court, March 2, 1925.)—It was held in this case that the refusal of a city commission to permit abandonment of a street railway line was not unconstitutional deprivation of property, even where the system as a whole fails to earn a fair profit, if the company does not use its right to surrender its franchise and discontinue operation entirely.

(Western and Atlantic RR. Co. v. Georgia Public Service Comm., U. S. Supreme Court, April 13, 1925). The decision supported a rule of a state commission requiring a permit to abandon railway sidetracks, as a proper exercise of the state's police power and not a direct burden upon interstate commerce. The rule was held constitutional, even where operation of the particular unit of the property was not profitable.

(7) **Maintaining Rates** (Southern Utility Co. v. City of Palatka. U. S. Supreme Court, May 11, 1925.)—An agreement between a public utility and a city to maintain a specified schedule of rates remains a binding contract, even though the rates become unremunerative for the company.

STATISTICS OF TRANSPORTATION

By H. L. Caverly
Professor at the University of Michigan

A. American Railway Express Company, Financial

(Compiled from Reports of Am. Ry. Express Co.)

Calendar Year	1922	1923	1924
Charges for transportation	$291,349,315	$309,579,474	$287,281,416
Cost of express privilege	142,323,022	155,736,205	139,997,384
Revenue from transportation	$149,026,293	$153,843,269	$147,284,032
Other revenue	3,476,877	3,600,492	3,355,751
Total operating revenue	$152,503,170	$157,443,761	$150,639,783
Expenses, taxes, etc	151,395,591	156,609,890	149,594,315
Net operating income	$ 1,107,579	$ 833,871	$ 1,045,468
Other income	1,956,038	1,851,290	1,458,258
Total net income	$ 3,063,617	$ 2,685,161	$ 2,503,726
Surplus, after dividends	695,200	381,249	203,479

B. Telephone Systems in the U. S.

(Including systems reporting $10,000 or more annual receipts.)

(Compiled from Reports of Bureau of the Census.)

Year	1917	1922
Number of systems	2,200	1,323
Number of public exchanges	12,294	10,666
Number of private branch exchanges	80,914	102,622
Miles of pole line	780,200	694,567
Miles of wire	27,298,026	35,502,983
Number of telephones	9,953,710	12,295,234
Estimated number of messages	19,809,061,085	21,901,387,070
Gross revenues	$ 372,501,800	$ 656,823,908
Expenses, taxes and fixed charges	313,103,060	560,159,965
Net income	59,398,740	96,663,943
Total assets	1,665,120,922	2,595,396,033
Plant and equipment	1,435,912,142	2,129,773,760
Permanent investments	99,484,744	248,625,115
Cash and current items	82,026,232	156,485,584
Capital stock	665,944,471	1,001,428,084
Funded debt	503,129,399	736,898,021
Net surplus	148,960,148	226,305,722
Number salaried employees	44,705	57,764
Salaries	$ 46,566,869	$ 94,006,233
Number wage earners	199,785	232,569
Wages	$ 123,088,197	$ 247,531,589

C. Land Telegraph Systems in the U. S.

(Compiled from Reports of Bureau of the Census.)

Year	1917	1922
Number of systems	21	19
Miles of pole line	241,012	252,991
Miles of single wire	1,888,793	1,849,312
Number of messages	155,263,206	185,841,267
Number of telegraph offices	28,865	27,253
Total revenues	$ 92,954,370	$130,538,660
Telegraph revenues	91,312,567	128,630,859

SOCIAL CONDITIONS AND AIMS

DIVISION XXII
JUSTICE AND MAINTENANCE OF ORDER

CRIME CONDITIONS IN THE UNITED STATES

By Frederick L. Hoffman, LL.D.
Consulting Statistician, Prudential Insurance Company of America

Bad State of Affairs.—The crime situation in the United States has never been worse than now. Evidence is absolutely convincing that criminal activities are being organized and carried out with consummate skill by an element of considerable intelligence and amply supplied with the necessary funds. The situation is giving most serious concern to all who believe that far-reaching measures and drastic changes in our judicial administration are required to bring about a return to more normal conditions. The tendency affects every phase of criminal activity, but is more pronounced in crimes against the person than crimes against property.

About the former group, the outstanding fact is that the United States has the highest homicide record of any civilized country. The record of murder victims is reflected accurately by the homicide mortality statistics. Statistics of this character permit of a reasonably exact comparison with other countries. The result is invariably decidedly to the disadvantage of the United States. In 1924, on the basis of a conservative estimate, not less than 11,000 persons were murdered in this country. There are no judicial statistics which would justify definite conclusions as regards the number of murderers apprehended, indicted and adequately punished, but there are reasons for believing that but a fraction of the offenders are ever brought to justice.

Lack of Convictions.—In a recent address, Judge John C. Knox of the United States District Court stated, on the basis of the record of the Chicago Crime Commission, that for 991 murders reported in that city from January 1, 1921, to November 1, 1924, there were only 250 sentences. He adds the following comments:—

> "The lawbreaker of the present day has at his command every aid and facility afforded by the dissemination of knowledge and the advances in science which has characterized these latter years. Given a swift automobile, a repeating pistol, a telephone with which to arrange plans with a confederate, and the requisite amount of nerve, coupled with the knowledge that our fundamental law is unduly considerate of criminals, the murderer of the highway may proceed to carry out his purpose with comparative security.
>
> "He is aware that he cannot be interrogated against his will; he knows that his house cannot be searched except with the loss of much time and the expenditure of great technical effort by prosecuting officials.
>
> "Under the influence of the writer of scenarios and the dramatist there is a popular impression that 'frameups' constitute the chief occupation of those charged with the detection and punishment of crime. Distrust of police testimony is the result. In short, the perpetrator of a major crime realizes that his offense, if prosecuted at all, will be disposed of with the ponderous and slow-moving machinery of the seventeenth century manufacture."

Homicidal Death Rates.—For recent years the homicide rate of the United States has been about 8.4 per 100,000, as against for England and Wales, 0.5 per 100,000, for Scotland, 0.2, for Ontario, 1.6, for Australia, 1.6, and New Zealand, 1.4, but the average rate of the United States fails to reveal the extraordinary high rates for certain cities and sections of the country, particularly in the South.

Memphis, Birmingham, Jackson and other Southern cities all have a local homicide death rate very considerably above the average. It requires no extended investigation to disclose the lamentable fact that the primary cause of our high murder rate is the ease with which firearms can be obtained by mail from firms not unwilling to make a considerable profit from the direct encouragement of murderous practice. Certain of our large mail order houses have of late, however, discontinued the practice but the evil is one of great extent and requires to be effectively dealt with by Congressional legislation.

Lethal Weapons and Materials.—About 70 per cent. of all the murder deaths of this country are directly the result of firearms. Quite recently there was a case of a boy seven years of age who shot his sister, age five, because she called him an offensive name. He obtained the weapon by opening a drawer in which the pistol was kept by his father. His only explanation was, "I was awfully mad and I meant to shoot her." Thus the crime trend is extending downward to the younger ages and permeates every section of organized society.

What is true of firearms is also true of poisoning. Poisonous substances can be obtained without difficulty in most sections of the country upon the specious plea that the material is required for a lawful purpose. There is the utmost urgency of decidedly more stringent safeguards than are at present in vogue. Evidence available also tends to prove that crimes against the person are becoming more brutal. The callousness of some of our criminals is appalling. The Franks murder case is but one of a number of recent crimes indicative of a state of mind which cannot be otherwise thought of than as diseased and the direct result of present day conditions.

An enormous literature is disseminated among the young which glorifies crime and the criminal, and the ease with which the consequences may be escaped by skillful methods. There are articles directly suggestive of new criminal practices, with every assurance of success and escape from punishment. Our murder trials are often a farce and an insult to public intelligence. Murderers are dramatized and made heroes while public resentment is shown towards judge and jury in their attempt to enforce the law. The recent Chapman trial is a sorry illustration of the state of public mind in this respect. The outlook at the present time gives assurance that this criminal will finally be hanged as he deserves.

The two most important improvements in recent years are the organization of the National Crimes Commission, of which Mr. F. Trubee Davison is Chairman, and the organization of a similar commission to bring about Congressional legislation regarding the sending of pistols through the mails, through the efforts of Mr. Mark O. Prentiss. Experience has shown that organized movements of this character are absolutely necessary if only for fact-finding purposes to place the true situation plainly before the public.

Capital Punishment.—This has of late years received considerable attention and a strong opposition to the death penalty is developing. In my own judgment, in the light of such investigations as I have made and participation in two electrocutions, the indications are that capital punishment is antiquated and does not serve the purpose of an effective deterrent. Juries are reluctant to impose the penalty and Governors are reluctant to enforce it. It seems established that its universal abolition would speed trials for murders and lead to the more prompt conviction of the murderer. The long delay in most of our criminal trials is a national disgrace and the placing of dangerous criminals on the parole system is a questionable procedure. There is much to be said in its favor regarding minor offences, but in the case of life prisoners, it would seem that the prerogative of exercising clemency should only be exercised in very rare cases. The parole system in Massachusetts seems to have worked well and to have done much good for the rehabilitation of the criminal element as useful members of organized society.

Crime Statistics.—The most urgent need of the present day is the initiation of a system of uniform judicial statistics corresponding to the efforts that have been successful in establishing uniform national statistics of births, deaths, marriages and divorces, etc. The crime statistics collected by the Census Office at decennial intervals are of little value. There is urgent need of more drastic reforms in this direction, for until the facts of the situation are brought plainly to public attention and dealt with on the basis of critical as well as a strictly impartial analysis, the true nature of the crime problem cannot possibly be understood on the part of all concerned.

Police.—Another urgent need is for more adequate police protection in both cities and rural sections. The admirable precedent of State Police in Pennsylvania, New York and other sections should be adopted on the part of every state of the entire United States, including Alaska. A precedent in this respect is the Royal Mounted Police of Canada which has a record not matched by any similar organization anywhere. The Canadian murder rate is low, the apprehension of criminals is almost a certainty, convictions are prompt and sentences are severe. It may also be said that when the death sentence is imposed in Canada it is almost invariably carried into effect.

It goes without saying that our police should be better paid, while the force should be increased to meet the more complex crime situation resulting from a rapidly increasing population aggregate.

Crime Against Property.—Crimes against property have likewise increased enormously and the amount of stolen property runs possibly into billions in the course of a few years. All that is true of a lax judicial administration as regards crimes against the person is even more true regarding crimes against property. The question may be raised as to whether restrictions should not be imposed upon bonding companies, which in many cases facilitate the escape of the criminal from justice and punishment.

Finally reference may be made to an increase in arson, directly encouraged by over-liberal practices on the part of certain fire insurance companies who fail to make adequate inquiry into the causes of the fires or the circumstances connected therewith. The president of the Glens Falls Insurance Company, Glens Falls, N. Y., has recently made some startling statements as regards the increase in arson during recent years which are deserving of thoughtful consideration.

In its last analysis, crime is a disease of society which can be cured only by more thorough education making for character and discipline rather than for intellectual or material and worldly success. There are reasons for believing that present day educational efforts in this respect fall lamentably short of the ideal.

MOB VIOLENCE AND LYNCHING

By James Weldon Johnson
Secretary, Nat. Assoc. for Advancement of Colored People

History.—With the exception of sporadic riotous outbreaks during strikes or occasioned by industrial disputes, race riots and lynchings during the past few years have centered about the relations of white and colored people in the United States. Mobs have been formed for the most part to lynch colored men and in some instances colored women, although white people have been among the victims. Lynch law, formerly applied in frontier times to horse thieves, gamblers and other undesirable elements of the community, has become almost exclusively the means of the white group for terrorizing the colored group.

The years immediately preceding 1925 showed a sharp decline in the number of lynchings. An organized, persistent and nation-wide campaign undertaken some fifteen years ago by the National Association for the Advancement of Colored People, in the course of which lynchings were investigated and the facts established, made clear to a large section of the American public that lynchings do not, as had been commonly supposed, occur only in punishment of the crime of rape. The National Association for the Advancement of Colored People, in the only authoritative compilation of the kind, "Thirty Years of Lynching," to which annual supplements have been added since its publication in 1919, made clear that less than 20 per cent. of the 4,000 victims of lynching mobs in the United States have been accused of rape.

Dyer Anti-Lynching Bill.—Growing sentiment in favor of a federal anti-lynching bill, such as was sponsored by Representative Leonidas C. Dyer of Missouri, passed by a vote of 231 to 119 in the House of Representatives in 1921 and blocked by a filibuster of southern senators in the Senate, brought home to state officers the necessity for state action if states rights were not to be further infringed. The result of the strong sentiment in Congress for such a federal law, and the agitation for its enactment by the National Association for the Advancement of Colored People, was a sharp decline in the number of lynchings from 61 in 1922 and 28 in 1923 to 16 in 1924, and during eleven months of 1925 there were only 14 lynchings.

Anti-Lynching Organizations.—In the past few years, following the lead of the Advancement Association, other bodies, such as the Federal Council of Churches and the Inter-racial Committees of the South, have undertaken to organize public sentiment against mob law. In consequence newspapers and public men generally have taken up the burden of creating an anti-lynching sentiment and in a number of cases during the year mobs have been repulsed by sheriffs and jail officers who have not hesitated to inflict casualties in order to maintain due process of law. One such episode occurred in May when five members of a mob were shot by officers guarding two negroes in a jail in Dallas, Tex. In North Carolina sentences ranging from thirty years to two years in prison were imposed upon five members of a mob which had mutilated a white man after removing him from a local jail.

Atrocious lynchings still continued to be reported during the year 1925, however. One insane patient was dragged from a Georgia institution and lynched by a mob. A colored man, who maintained his innocence of an attack upon a white woman, was beaten, mutilated and finally burned alive by a mob in Mississippi, one of whose members was quoted by the Memphis *News Scimitar* as boasting that there would be no investigation, prosecution or conviction of any mob member.

Attacks on Negro Holders of Real Estate.—Another occasion for mob violence assumed prominence during the year 1925. This was the encroachment of colored people upon residential sections in northern cities, which had been inhabited theretofore by white people. The expansion of colored residential sections, owing to the northward migration of colored people from the South, and the consequent enormous increase in the colored population of northern cities, provoked hostile demonstrations in many parts of the country. On Staten Island, New York, the home of a colored postman was repeatedly attacked, his fire insurance cancelled and threats made against his life. In Los Angeles, Pittsburg, Roanoke, Va., Kansas City, Mo., and other cities, homes were bombed or threats made against colored residents in white neighborhoods. In Detroit, on September 9, in the course of a mob demonstration against the home of Dr. O. H. Sweet one man was wounded and one killed. Eleven colored people in the house at the time were tried on charges of first degree murder. This case became a dramatic focus in the widespread situation through the retention of Clarence

Darrow by the National Association for the Advancement of Colored People to defend the accused colored people.

RECORD OF LYNCHINGS FOR 1925

February 17.—Cruger, Miss.: *Hal Winters* and an *unidentified Negro* were taken from Holmes County officers and lynched. Winters was alleged to have shot and killed Wisley P. Martin, a plantation manager. He was accompanied by the unidentified man whose connection with the crime is not clear.

February 26.—Benton, La.: *Joe Airy*, alleged slayer of a state highway officer, was lynched by a mob, near Benton, after being wounded by a deputy sheriff, who, it is said, fired after Airy had drawn a revolver when surrounded by a posse. The mob then hanged the Negro.

March 2.—Rocky Ford, Ga.: An unidentified Negro, said to have confessed attacking a fourteen-year-old white girl, was burned at the stake two and a half miles from Rocky Ford. . . . He was manacled, wood was piled about him, soaked with gasoline and fired.

March 20.—Waverly, Va.: A Negro accused of attacking a white woman was taken from the Sussex County Jail at Waverly by a mob and lynched.

April 21.—Tylertown, Miss.: One *Buckley* was lynched by a mob, accused of striking a six-year-old white child. He had been in jail a month, being unable to secure bail. He finally found some one to go his bail, was released and went to his home. He had not been at home very long before a mob formed, surrounded his home, broke down the doors, took him out and hanged him.

April 13.—Jellico, Ky.: *Jim Evans*, accused of killing the Chief of Police, was shot to death by a mob of 200 white citizens. The Chief of Police had gone to Evans' home to arrest him on a charge of being drunk.

May 13.—Seminole County, Fla.: *Jack West* was taken from a train and lynched near Longwood, Seminole County. The body, riddled with bullets, was found tied to a tree. West had been arrested charged with house breaking and assault on a three-year-old white girl. He was acquitted of the charge.

May 30.—Camden, Ark.: An unidentified man was taken from the hands of county officers near Camden and strung to a tree and shot to death by a mob said to number about a hundred. The man was suspected of having attacked a white woman.

June 18.—Castlegate, Utah: *Robert Marshall*, slayer of the City Marshal, Milton Burns, was hanged by a mob near Castlegate. On June 15, he shot and fatally wounded Burns who had some months previously taken a pistol from him.

August 7.—Excelsior Springs, Mo.: *Walter Mitchell*, accused of attacking a white girl, was taken from jail by a mob, and hanged.

August 12.—Scobey, Miss.: *Sidney Towns* (insane), said to have killed an aged white man and fatally wounded the man's sister, was taken from the sheriff by a mob of seventy-five men and his body was riddled with bullets.

September 20.—New Albany, Miss.: *L. Q. Ivy* was taken from officers and burned at the stake by a mob. Ivy was said to have confessed to attacking the daughter of a farmer eighteen miles from New Albany on September 18. He was returned to the scene of the attack and burned to death.

September 20.—Milledgeville, Ga.: *Willie Dixon*, inmate of the State Insane Asylum, said to have killed a nurse at the asylum, was chained to a tree and beaten to death by a mob. The coroner's jury returned a verdict that the victim met his death at the hands of parties unknown.

MOVEMENTS TO CHECK CRIME

By Louis N. Robinson

Secretary, Pennsylvania State Penal Commission

National Crime Commission.—Leaving out of account movements not directed primarily toward reduction in crime nor promoted by those whose main interest is in the crime problem, within the last year only one new organization seems to have been founded for the express purpose of reducing crime, namely, The National Crime Commission, with headquarters in New York. Officers of this Commission are: Chairman, F. Trubee Davison; treasurer, General Samuel McRoberts; and chairman of the Finance Committee, Charles H. Sabin.

This Commission has so recently completed its organization that it has as yet hardly begun its work. Its primary purpose appears to be to awaken public opinion and to make available facts upon which conclusions may be based and action taken. The following Sub-Committees have been appointed: Local Organization; Police; Social, Educational and Industrial Conditions Affecting Crime; Legal Procedure, Prosecution and Judicial Administration; Medical and Expert Testimony; Legal Education and Standards of Professional Conduct, Pardons, Probation, Penal Laws and Institutional Correction. In addition it is planned to establish a statistical and research bureau in the Executive Office of the Committee in New York.

Prisons.—Of considerable significance to those who feel the need of expert assistance in the field of Penal Administration is the appointment by the Russell Sage Foundation of Dr. Hastings H. Hart as consultant in the field of Delinquency and Penology. Dr. Hart was for years the director of the department of Child-Helping of the Russell Sage Foundation. Even in this position, much of his time was given to this work especially along the lines of care for juvenile delinquents. At his own request, he was released from this department in order that his entire time might be at the disposal of groups interested in Penal Reform.

Dr. Hart has made a careful study of United States prisoners in county jails and workhouses throughout the United States. This study should be read in connection with Joseph F. Fishman's book, *Crucibles of Crime.* Dr. Hart's special knowledge was also utilized by the Federal Grand Jury of Houston, Texas, in the making of their report, and his services have been recently utilized in both Chicago and St. Louis.

Prison Labor.—Some two years ago the National Committee on Prisons and Prison Labor developed a scheme of marketing prison made products. Feeling the State Use System of prison labor to be the coming system, they endeavored to broaden this concept of prison employment by making it a *States* Use System. Under this plan a state could sell not only to itself and its own institutions but to other states and the institutions of these other states. This would make possible the allocation of industries between the states and a broader, yet not an open, market for prison products. To one who knows the evil results to prisoners of idleness and of employment under bad conditions, any movement that promises the sane employment of prisoners must be looked upon with sympathetic interest and encouragement.

Probation.—The National Probation Association, Dr. Charles Platt, president, Mr. Charles L. Chute, 370 Seventh Avenue, New York, secretary, continues actively at work in the field of probation. It has recently completed a state-wide survey of probation and parole work in Wisconsin, and is planning a similar survey of probation in Michigan. In coöperation with the Penal Affairs Committee of Pennsylvania it has carried on an extensive survey of probation in all the counties of that state. How necessary such surveys are, can be seen from the situation in Pennsylvania where numerous counties make no use whatsoever of adult probation, and where several counties are without a juvenile probation officer.

Through the efforts of this organization, the enactment of the Federal Probation Law was secured during the final week of the last session of Congress. It will now be possible for Federal Courts to place on probation, offenders who can only be harmed by commitment to Federal prisons and county jails. The Association is seeking to bring about an orderly development of probation through the work of committees on standardization. The Association itself has prepared a model juvenile court law, and its committee on records and statistics has produced a set of blank forms for juvenile probation case records. It has another committee on domestic relations courts and we may soon look for recommendations both as to law and as to administrative records in this rapidly developing field of probation work. The extension of the use of probation brings with it inevitably problems of administration, and it is the aim of this association to be in a position to throw light on these problems as they arise.

Penology.—In several of the states, both the citizens and the public officials have displayed considerable interest in the problem of crime. Notable work has been done by the Missouri Welfare League and by Dr. Glenn Andrews, state prison inspector of Alabama. In no other state has this interest been greater than in Pennsylvania where we have for the first time had the State Department of Public Welfare and private agencies, notably the Penal Affairs Committee of Pennsylvania, working together for improvement in the field of Penology. As already stated, the National Probation Association coöperated with the Penal Affairs Committee in conducting an extensive survey of probation throughout the state. This survey was not confined, however, to probation alone, but included the study of parole and of county jails. The study was made with the full knowedge and coöperation of the State Department of Public Welfare. Another example of cooperation between public officials and private citizens is offered by the survey that is now being made of the Philadelphia Municipal Court by the Bureau of Municipal Research. After a conference with a group of interested citizens, the Presiding Judge of this court extended an invitation to the Bureau of Municipal Research to make a thorough-going study of its work. At the present time this work is being carried on with the help of the best equipped men and women in the country. The State Department of Public Welfare has also of its own initiative set about transforming the old Penal Institutions of Pennsylvania and has obtained already notable success in the Western Penitentiary at Pittsburgh.

Prison Reform.—The Penal Affairs Committee of Pennsylvania, to which reference has already been made, is very active. Through its influence with the legislature of 1925, the reformatory for women at Muncy is to be enlarged to care for all women receiving a sentence of one year or more, and the parole system of the state studied by a state commission. Believing that careful investigation should precede the formulation of plans, it is gradually building up a staff of experienced people to care for this work. The Pennsylvania Prison Society, oldest of all prison societies, has also taken on a new lease of life. A recent bequest of money has enabled the Committee on Discharged Prisoners of this society to engage a well trained social worker to take care of this part of their work.

To one who is at all conversant with the problems of criminology, all these efforts to stamp out crime that have been enumerated seem, in comparison with the need, pitifully weak and insufficient. They are, however, symptomatic of the increasing interest that is being taken in the problem. A hundred years ago, it was a topic of live concern. There followed then long years of apathy and neglect. Perhaps the recent outbreak of crime and violence will compel us to think through this problem again after this long lapse of years. There is great need for organized effort in each state if any headway is to be made in the effort to stamp out crime. Those who come into the work must remember, however, that it is a problem not in cavalry tactics, swiftly executed, but in trench warfare, long drawn out.

ADMINISTRATION OF CRIMINAL JUSTICE

By Andrew A. Bruce
President, American Institute of Criminal Law and Criminology

Increase of Crime.—The year 1925 furnishes a promise for the future rather than a record of accomplishment. In it has been brought to public attention the seeming inadequacy, if not the breakdown, of our whole criminal administration, and the year is marked by the increase in the number and activity of private organizations whose purpose is not merely to investigate the causes of crime but to stir the public officials to greater activity in its suppression.

Prior to the World War and for some time after its termination the emphasis of the reformer had been laid on the reformation of the criminal and the amelioration of his condition and but little attention was paid to the defects in the administration of justice which interfered with his arrest and punishment. The large increase in the crimes of violence, however, which followed the war has resulted in a feeling of unrest and dissatisfaction and to such an extent that speakers and writers are everywhere urging not only a reform of our courts and of our police organizations, but a recasting of the very foundations of the criminal law and are questioning the applicability to this age of the ancient safeguards such as the writ of habeas corpus, the freedom from self-incrimination, the unanimous verdict of twelve men and the liberal bail system which, in the age of a bloodthirsty criminal code, "liberty threw around her children."

Hoffman's Investigation. — Frederick L. Hoffman, the consulting statistician of the Prudential Insurance Company of America, in a series of articles startled the nation by statistical proof of the large number of homicides in the United States, and crime commissions such as those of Chicago, Baltimore, and Cleveland equally surprised the country by their records of crime and of administrative inefficiency. At first spasmodic efforts were made to deal with the situation in the various localities. In 1925, however, these records were given a wider publicity and we now seem to be at the opening of a new era of a nationwide reform in the matter of the administration of criminal justice. At first Mr. Hoffman and the various reform organizations were content to urge a greater publicity and a federal inquiry into the whole matter, but the demand now appears to be for more drastic action and there is every evidence that such will be the result. Among the protagonists of this policy has been Marcus A. Kavenagh, for many years a trial judge in the city of Chicago and for many years a careful though perhaps a more or less prejudiced student of crime and of the criminal. On March 15, 1925, in speaking before the St. Louis Bar Association, he stated that "from a careful estimate" he had concluded that there were "at large, unpunished and unafraid, in the United States, at least 135,000 crimson-handed women and men who unlawfully have taken life," and that though 8,500 would be a conservative estimate of unlawful homicides a year during the last twenty years, there were on the date of his address confined in the penitentiaries not more than 18,000 persons who had been convicted of such offenses. He said that after making due allowance for executions and other kinds of deaths there remained his estimate of 135,000 persons, which was more than all our clergymen of all denominations, all our male teachers put together, and 52,000 more sluggers at large than we have policemen. He also stated that competent observers reckoned that there are in this country 350,000 men and women who live partly or entirely by crime and that the number is increasing with incredible rapidity.

Expert Discussions.—Various reports committees of the American Bar Association and of other organizations have made similar statements and an invidious comparison has been drawn by most of them between the administration of the law in America and in England and in the English dominions. It is true that many of these statements may be exaggerated and that at the annual meeting of the American Bar Association which was held at Detroit, Michigan, in August, 1925, Oscar Hallam of Minneapolis, who was formerly a chief justice of the Supreme Court of Minnesota and for many years a trial judge, questioned the accuracy of many of the figures that have been presented and especially criticised the American tendency to use England as a criterion and the experience there as a conclusive proof of the shortcomings of the American system of criminal administration. Even he, however, admitted the seriousness of the situation. "Homicide in the United States," he said, "alarming as the total is, shows an average annual decrease. Increases are recorded among the colored population and in many of the larger cities. The aggregate of the other crimes has materially increased, due partly to increases in holdups and in banditry and due largely to increase in traffic-law violations, liquor offenses, and the mass of new crimes. Old-fashioned crime, such as burglary, larceny, from the meager statistics available, seems to show little increase. . . . The crime record of Canada and that of territories and cities and towns in the United States adjacent to Canada and similarly situated is much the same."

But be the facts what they may, the large number of crimes of violence in the United States and the publicity that has been given to them by the press (and perhaps it is this very publicity and our more adequate means of information which makes us believe that we are more lawless than our ancestors) have aroused the reformer to a new activity. We are still prepared to believe with Judge Harry Olson of Chicago that much of crime is due to heredity and that the incipient criminal and the moron should be segregated before his crimes have been committed, but we are none the less insistent that criminals of all sorts shall be arrested, segregated, and punished; and one has only to read the reports of agencies such as the crime commissions of Chicago, Baltimore, and Cleveland to be satisfied of the fact that a very large proportion of our criminals are not arrested and much less punished. Appalling as the figures may be, the total number of our confirmed criminals does not exceed one third of one per cent. of our population, and we are more and more becoming impatient with a system of law enforcement and even of substantive criminal law which will allow this handful of men and women to terrorize and to defy millions of law-abiding citizens.

The problem indeed has become nationwide and national organizations are preparing to enter the field. Not only have the Bar Associations of California, Missouri, Illinois, and other states, either alone or in conjunction with other public agencies, undertaken a survey of their whole criminal law; not only has the American Institute of Criminal Law and Criminology, at the request of the local authorities, undertaken a survey of the criminal administration of the city of Memphis, Tennessee, and the various societies and organizations of Chicago undertaken a similar enterprise, but the American Law Institute, the American Bar Association, and the National Crime Commission have all entered into the field.

Philadelphia Police.—On the other hand, a noteworthy experiment in effective police administration will be terminated on December 31, 1925, by the refusal of President Coolidge to longer extend the leave of absence of Brigadier-General Smedley D. Butler of the Marine Corps, who at the request of Mayor Kendrick of Philadelphia had been allowed to accept the appointment of chief of police of that city. The practical success of this system was perhaps evidenced by the request of both Mayor Kendrick and Senator Pepper for the reappointment of the officer. But whether the experiment is one which will be popular in our American democracy is a matter of some doubt. It is questionable whether we will ever be able to apply to a city police force the methods of the American army and whether the American people, and especially the American labor unions, will be willing to have our police forces subject to other than local political control. The function too of the policeman is not that of the private soldier. A private soldier may be dishonest and personally unreliable in an army and yet be an effective unit when he cannot be such in a police force. The private soldier does what he is ordered to do. He has little personal responsibility. Over him and directing him is his corporal and above the corporal is the sergeant, and so on up to the commanding officer. On his own beat, however, the policeman is more or less an autocrat. He has a large territory to patrol. He must use his own judgment, his own discretion, and his own initiative. Though in Philadelphia the head of the police force was a military officer of efficiency and experience, the troops that he commanded were subject to all of the temptations and all of the restrictions of association and environment and of local politics. We have been brought up in an atmosphere of self-government and it is doubtful whether our local politicians will ever be willing to dispense with the direct control of their administrative and police officers, which in its essence is so detrimental to an efficient and fearless criminal administration.

National Probation.—For the amelioration of the condition of the criminal, there was in 1925 but one notable measure. By an act which was signed by the President of the United States on March 3, 1925, Congress authorized the United States district judges in proper cases to suspend sentences and to place the offenders upon probation "after conviction, or after a plea of guilty or nolo contendere for any crime or offense not punishable by death or life imprisonment." Probation systems already existed in all of the American states either under legislative sanction or an assumed inherent power of the courts, and the act in question merely extended the practise to the federal courts. It was significant, however, as it evidenced the fact that though as a people we are determined to suppress crime we are still humane.

Crime Commissions and Associations.—National Crime Commission, New York. Baltimore Criminal Justice Commission, James M. Hepbron, Managing Director. Crime Commission of Los Angeles, 940 Merchants National Bank Building, Raymond I. Turney, Director. Law Enforcement Association of Kansas City, 511 Continental Building, Kansas City, Missouri, Ward C. Gifford, Executive Secretary. Cleveland Association for Criminal Justice, 1237 Guardian Building, J. M. Shallenberger, Operating Director. Chicago Crime Commission, 21 N. La Salle St., Chicago, Ill., Henry Barrett Chamberlin, Operating Director. The Commonwealth Club of California, San Francisco, Section on Administration of Justice, Hugh Henry Brown, Chairman, 800 Foxcroft Bldg., San Francisco, Calif. Missouri Association for Criminal Justice, Arthur E. Laskley, St. Louis, Missouri, Operating Director—Missouri.

PRISONS AND PRISON ADMINISTRATION

BY AUSTIN H. MACCORMICK

PROFESSOR AT BOWDOIN COLLEGE

Prison Congress.—The Ninth International Prison Congress was held in August in London. About 500 delegates from over fifty countries attended the sessions. The official delegates from the United States, appointed by the President, were Dr. Herman M. Adler of Illinois, Hon. Sanford Bates of Massachusetts, Dr. Amos W. Butler of Indiana, Dr. Hastings H. Hart of New York, Mrs. Jessie D. Hodder of Massachusetts, Dr. Charles H. Johnson of New York, Dr. R. F. C. Kieb of New York, Lewis E. Lawes of New York, Dr. Frank Moore of New Jersey, William F. Penn of Pennsylvania, Dr. R. R. von Kleinsmid of California and J. J. Sullivan of Minnesota.

The method followed at the Congress was a new one. Instead of papers being read they were printed and were discussed in sectional sessions, which in turn presented resolutions for discussion and adoption at the general sessions of the Congress. The sectional sessions discussed subjects under the general heads of Legislation, Administration and Prevention. Such resolutions as were passed at the general sessions became the official acts of the Congress.

The annual congress of the American Prison Association was held this year at Jackson, Mississippi, from November 7 to 14. Hon. Sanford Bates, Commissioner of Corrections of Massachusetts, was elected president of the Association.

Officials.—During the year several wardenships have changed hands. One of the most important changes was in Indiana, where Warden Fogarty resigned after thirty-three years of prison service and was succeeded by his deputy, W. H. Daly. Mr. Fogarty belonged to a group of wardens whose administrations began in the days of the old prison system. Only a few representatives of this group of long-service wardens now remain in office.

In Maryland P. J. Brady succeeded Col. C. B. Sweezey in June. Other wardens who have been appointed during the present year are Richard E. Davis in Utah, A. B. Middleton in Montana, W. H. Mackey in Kansas, Harry H. Jackson at Jackson, Michigan, J. W. Wheeler in Idaho, and Morris Fish in Maine. At the Southern Illinois Penitentiary the state superintendent of prisons, E. J. Green, has been acting warden since Jan. 1, 1925.

The experiment in dual control at the New Jersey Prison, where Calvin Derrick was appointed Director of Administration and Industries to take over many of the warden's duties, was apparently not successful. No successor to Mr. Derrick, who resigned, has been appointed. In several prisons forms of dual or multiple control may be found. This ordinarily takes the form of a separation of the control of the industries and the prison proper, the former being put under a superintendent of industries who is not directly responsible to the warden. The idea of a plural executive is applied to the highest degree in Missouri. There the board of five commissioners, which controls four penal institutions, is resident at the prison. Four members of the board have charge of distinct departments: discipline (under a commissioner called the warden), pardons and paroles, farms, and industries. The fifth commissioner, who is director of the board, is the coordinating head, but the actual management of the prison is divided among the four commissioners named.

Construction.—Some new construction of importance has been carried on during the year, but in the main the prison plants of the country are progressing slowly toward the accepted modern standard for well-rounded plants. Practically every prison in the country is over-crowded and several prisons have populations double their ordinary capacity.

In Illinois at the new Joliet prison, work was resumed this summer on the fourth of the eight circular cell-houses for which the plans call. The wall, administration building, isolation building, mess-hall and commissary department, and several of the shops have been completed. About half the population has been transferred to the new prison. The prison is being built with inmate labor.

In California at San Quentin appropriations have been made available to complete a cell-house which was begun in 1907 and on which work was discontinued in 1912 after the four walls had been completed. Since the work stopped the population of the prison has practically doubled and a serious condition of over-crowding exists. Ground was broken this fall for a new woman's prison, to be built just outside the walls of the prison proper. At present the sixty women prisoners are confined in a section of the men's prison designed for twenty-seven inmates.

At Leavenworth work is progressing slowly on the imposing dome of the administration building and on the shoe-shop, which has been under construction for seven years. This shop is designed to provide work for a thousand prisoners, about one-third of the population. As there are no industries at Leavenworth the immediate completion of the shop is imperative. All construction work on this building and on the dome is being done by the inmates.

Michigan has begun work on a new prison at Jackson, about three miles from the city. It is designed for 5,510 prisoners. The wall, which is first being constructed, will enclose sixty-four acres, the largest prison enclosure in the country. Here also inmate labor will be used in the work of construction.

Work on the new prisons at Sing Sing and Rockview (Pennsylvania) is practically at a standstill. At each of these prisons a cell-house housing about 250 men has been completed. At Great Meadow, the so-called "honor prison" of New York state, the prison is now being enclosed by a 24-foot wall.

Industries.—The year 1925 has seen little improvement in the industrial situation in American prisons and it grows increasingly critical. Several prisons, notably Leavenworth among the larger and Montana among the smaller, have no industries and the problem of idleness is acute. Over half of the prisons in the country, including several of the largest and most important ones, suffer from semi-idleness.

In the middle west a small group of prisons have effective industrial organizations. In the Minnesota prison at Stillwater, for example, during the last fiscal year the industries paid the full cost of the prison, over $100,000 in wages to the prisoners and a net profit of nearly $40,000. The Wisconsin and Missouri prisons are self-supporting and the Michigan prison at Jackson has a good industrial organization with diversified and profitable industries.

The industrial situation in several of the older Eastern prisons is bad. At Sing Sing, for example, only 25 per cent. of the prison population is engaged in productive industry.

The Minnesota prison and others have demonstrated that prison labor can be made productive. Throughout the country, however, there is a general tendency to accept the theory that prisons should not be expected to be even approximately self-supporting. During the current year, as in past years, legislatures in various states have failed to pass appropriations providing adequate industries in the prisons.

Present conditions in prison industries indicate that the state-use plan alone will not be profitable until there is greater coördination between the prisons and the other state institutions or departments which constitute the prison market. In the smaller states it is becoming apparent that this plan is not likely to succeed, because of the limited market. A combination of the state-use plan with the state-account plan (production for sale on the open market) is proving more profitable than either plan alone. The opposition of labor organizations and of manufacturers is constantly directed against those prisons which have the state-account system, and constitutes the most serious obstacle to effective industrial organization in American prisons. During the summer of 1925, to cite only one instance, the refusal by union brick-layers to lay brick made at the Jackson prison threatened to cripple the large and profitable brick plant there.

One of the most significant industrial projects now being carried on in our prisons is the road-work in California, employing nearly 600 prisoners on a unique pay basis. Men in the road-camps are paid $2.10 a day by the State Highway Department and are charged for food, clothing, transportation, salaries of guards, and all other expenses of supporting the camps. The prisoner may receive a maximum of 75 cents a day in wages after these charges are paid. The road-work is highly successful and has been expanded this year.

The principle that prisoners should be paid a wage, charged to the cost of production, is becoming well established. The value of the wage is demonstrated most convincingly in those prisons which are successful industrially. In these prisons the daily wage ranges from 25 cents to $1.30 and is considered a necessary feature of effective industries.

Education.—In most of our prisons the educational work is still perfunctory, limited and ineffective. Only a few prisons furnish the type of instruction that appeals to adult prisoners: vocational courses combined with common school subjects closely related to the vocational work. The use of correspondence and university extension courses is gradually growing more general, and has brought some life into the educational work of the prisons where it has been introduced. No prison in the country today, however, has a complete and well-balanced educational program. The most advanced program is that of San Quentin, where the coöperation of the University of California through its extension courses has made possible effective educational work for several hundred prisoners. The study of prisoners taking these courses is supervised and there are additional courses in vocational and standard school subjects. The work is handicapped, however, by insufficient funds and inadequate class-rooms. Until late in 1925 there was no officer in charge of the educational work and it has been organized and directed by the inmates. In spite of all its handicaps it is the best educational program now being carried on in any American prison.

Parole.—The parole work in several states has been under fire during the past year. The opposition to parole in some states has been unintelligent and based on failure to appreciate the value of a proper parole system. In other states the attacks have resulted from alleged abuses and corruption. In Kansas this has led to an almost complete cessation of parole work, with an inevitably bad effect on the morale of the inmates. In Massachusetts, without any charge of abuses, there has been a gradual slowing up of the parole work. This has had a detrimental effect on the morale at the Charlestown prison. In Texas, where the governor has granted clemency in the form of pardon or parole in over a thousand cases during the past ten months, the administration has been attacked on this ground.

With opposition to paroles there has occasionally been an effort to nullify the provisions of indeterminate sentence laws. In Arizona prisoners have been sentenced to serve indeterminate sentences of 75 to 99 years and even of 150 to 160 years. In some cases the minimum and maximum sentences have been placed so close together that the maximum, which is reduced by law for good conduct, expires before the minimum sentence. Such breaking of the spirit of the indeterminate sentence law is manifestly unfair and absurd.

Inmate Participation.—The system of inmate coöperation, sometimes erroneously called "self-government," established by Thomas Mott Osborne over a decade ago in New York at the Auburn and Sing Sing prisons, is still in force. The principle of the system has also been applied successfully for the past five years in the Delaware prison and during the past year in the Maine prison. At Jackson the prisoners at the brick plant, eighty in number, are trusted with great responsibility in the conduct of their own work and discipline and are organized to exercise that responsibility. In various prisons all over the country there have been in minor points applications of the idea that prisoners can be trusted as a community to coöperate with the officials in matters of discipline and administration. The idea of inmate coöperation appears to be gaining ground yearly, although somewhat slowly.

General Summary.—While each year shows only comparatively slight progress in our prisons, the past two decades have seen remarkable changes in prison administration. This is largely due to the changed ideas of the real purpose of the prison. Recognition of the fact that prisons exist for the protection of Society and that men must be fitted to fit into the social order has led to the development of institutions having the rehabilitation and training of the inmates as their primary function. Not only are prison plants gradually changing, but the whole prison program is broadening, both in purpose and method. It is recognized that prisons must be educational institutions in the broadest sense. Toward the ideal, however, much progress is yet to be made. The prisons of today have to a large degree done away with the old abuses; they have not, on the other hand, developed their constructive features correspondingly. In most of our states the virtues of the prisons, where they have any virtues, are negative rather than positive. There is much to be done in the development of modern plants, effective industries, educational and religious work of a high order, and particularly in the setting up of agencies to train men in the duties and responsibilities of citizenship.

INSTITUTIONAL TRAINING FOR DEFECTIVE DELINQUENTS

By Walter N. Thayer, Jr.
Institution for Defective Delinquents, Napanoch, N. Y.

Problems.—The Defective Delinquent is the mental defective, who, through lack of proper early training or through bad association and environment, forms criminal habits.

In a majority of cases, investigation will reveal a defective heredity. This, in itself, is often productive of a bad environment and the formation of habits of delinquency follows as a matter of course.

Treatment of this individual so as to realize success to the greatest degree possible must comprehend training in habits of industry and obedience.

Training. — Academic training should be limited to the lower grades. Manual training and trade instruction should be afforded to the highest degree possible in each case. Successful treatment requires careful analysis of the individual case including therein physical, psychiatric, psychometric, educational and efficiency surveys. The personal and family history, as well as the individual's social and industrial history, should be investigated. Following these surveys the case is ready for training assignments. His accomplishments defined by his history should be compared with the levels determined by the psychometric and efficiency tests, and an effort made to train the individual in a way that will enable him to realize his possibilities. As a rule it will be found that he has fallen far short of this goal.

Academically the average Defective Delinquent has not progressed beyond the third grade. Industrially he is in the unskilled labor class—the "last man hired and first man fired" in the ups and downs of industrial life. He has no commercial basis upon which to sell his efforts and must rely upon a demand for the most menial type of laborer, although he may possess mechanical aptitude which has never had an opportunity for development.

The first thought should be the removal of all remediable physical handicaps as these may well be the proverbial "last straw." Secondly: train the individual educationally and industrially—particularly industrially—to somewhere near his highest possible level. In other words, endeavor to develop to a marketable extent any latent ability he may possess.

Rehabilitation. — Various factors create an inferiority complex which must be overcome if the subject is to be economically anything but a liability. Failure in school life and failure in industry have been followed by failure in society. Our subject rarely undertakes anything worth while, be it ever so simple, without expectation of failure from the very beginning. To rehabilitate him he must be trained sufficiently well in some operation within his scope to enable him to compete with his neighbor and produce a result that he himself can respect. Until this is accomplished he is beaten before he starts, and has absolutely no respect for his own ability, even though he may loudly proclaim his merits.

In addition to this a kindly but strict system of discipline should be maintained. This discipline must, in an intensive way, make up for the utter lack of such training in his formative and more impressionable years. It must be evenly exercised and even minor faults should be noticed and corrected.

If these men can be trained to react instinctively, in a social manner, it will go far towards their readjustment. The way to do this is instill the thought that obedience brings comfort and disobedience the reverse. Obedience gains and disobedience restricts privilege. This is the same rule that applies in society. Society grants privileges in direct proportion to our ability to use them in a social manner. Should we construe privilege or liberty to mean license, we find ourselves in trouble.

These men fail in civil life because of its complexities. In an institution where every necessity is provided for them and no great measure of responsibility is even expected they may adjust and function fairly well.

For this reason parole preparation should comprehend gradual increase in self-supervision, including as a final step in preparation a period in a colony at a distance from the institution. Careful observation of the reaction of the individual to the increased freedom and responsibility should make for intelligent selection of parole material and this for a minimum of failures among those returned to society.

Accordingly, parole environment should be selected intelligently, keeping in mind not only our subject's limitations, but his special abilities. Kindly, helpful, intelligent supervision on parole should be afforded.

Summary.—Careful analysis of each case—removal of physical handicaps—instruction in productive occupation to maximum of indicated ability—cultivation of social habits by an even enforcement of discipline—careful placement and judicious supervision on parole.

NEW LIGHTS ON CRIME AND DELINQUENCY

By Sheldon Glueck

Instructor, Department of Social Ethics, Harvard University

Preventive Work.—The outstanding project in the prevention of delinquency is the Commonwealth Fund Program. Proceeding upon the assumption that the roots of delinquency can in most cases be traced to the individual and social maladjustments of early childhood, the Joint Committee on Methods of Preventing Delinquency of the Commonwealth Fund launched one of the most practicable projects ever undertaken in coping with criminality. The Italian criminologists of the 19th century busied themselves largely with the study of the confirmed criminal and with broad programs of social reform as related to the prevention of crime. The American workers of the Commonwealth Fund turned to fundamental problems which in part are capable of solution even under the existing social-economic régime. Psychiatric clinics for the study and treatment of "predelinquents," "problem children," maladjusted youth in general have been set up in a few places.

Case Records.—The first and most important of these, the Bureau of Children's Guidance of New York, was established several years ago under the direction of Dr. Bernard Glueck. Considerable useful work has already been done in the study and treatment of problem children. But perhaps the most important work was the publication of a number of case records showing the mechanisms of youthful conflict and maladjustment at work and throwing much light on the technique of treatment of these problems. These records have become invaluable teaching material in courses in sociology and social work, and have set a high standard of investigation, analysis and treatment. As compared with the statistical study of individual "criminal traits" extracted from the living, acting personality of the delinquent, the studies of the Commonwealth Fund and similar studies shed considerable light on the intricate mechanisms of maladjustment and delinquency in the individual case.

Clinical Work.—The clinics of the Commonwealth Fund, together with the excellent clinics for the more general problems of mental hygiene established at various strategic points throughout the country by the National Committee for Mental Hygiene, serve as striking community demonstrations of the value of the immediate practical approach to the problems of delinquency and mental disorder. They have stimulated various cities to finance and establish similar enterprises of their own. Thus the principal aims of these clinics are bringing valuable results in arousing communities to their responsibility both in the causation of delinquency and in the all-important domain of preventive social medicine of which the treatment of pre-delinquency by means of psychiatric clinics is but a branch.

Visiting Teachers.—In addition to the clinical work of the Commonwealth Fund this project has greatly stimulated the visiting teacher movement. When it is remembered that considerably more than half of the time of children during their early school years is spent outside of the school, and that the school is but one source of youthful conflict and maladjustment, the importance of this movement becomes readily apparent. Visiting teachers, trained educationally, socially and psychiatrically, have been established in a number of communities by the Commonwealth Fund. Danger signals of conflict, such as truancy, misbehavior, inability to progress with studies, sex difficulties, etc., are reported to the visiting teachers. They investigate the homes and neighborhoods of the children, have them examined at psychiatric clinics, make contacts with other community agencies, plan programs of individual readjustment, and indirectly obtain much valuable information as a basis for necessary social legislation. By thus impressing upon parents, teachers and citizens generally the important fact that education for life barely begins where formal school learning ends, and that much of the failure, unhappiness, delinquency and dependency of adult life is traceable to neglect of this fundamental truth in childhood, the visiting teacher movement is helping to bring about a much-needed thoughtful attitude toward the problems involved.

Agencies.—Other important agencies of the first rank of scientific achievement in this field, to mention but a few, are the Judge Baker Foundation of Boston, under the able directorship of Dr. William Healy, pioneer in the scientific study of juvenile delinquency, and Dr. Augusta Bronner, and the work of Dr. H. M. Adler, State Criminologist of Illinois and of Dr. Miriam Van Waters, Referee in the Juvenile Court of Los Angeles.

If space permitted, other agencies dealing with "pre-delinquents" in various communities might be mentioned. These include various boys' and girls' clubs, "republics," etc. These sporadic efforts are important in that they reduce the volume of delinquency locally by providing healthy outlets for normal youth. Some of these agencies are more sentimental than scientific. But even they do valuable work in providing playgrounds, recreation rooms, dance halls, etc., frequently under trained supervision, and in attempting sympathetically to understand and deal with the problems of puberty and adolescence. In this way they successfully compete, in many instances, with commercialized pool-rooms, dance-halls and other breeding-beds of vice and delinquency.

Legal Machinery for Coping with Crime.—Turning now to the important work which has been accomplished in the study of society's legal machinery for coping with the problem of criminality, the great Cleveland Foundation Survey of the Administration of Criminal Justice takes the first rank. Other surveys of different phases of this problem have been made at various times; the Cleveland investigation, however, is the first to have covered the entire legal process as a unit,—from the point of arrest of the offender to the point of his parole and return to the community,—and this in its social setting. This epoch-making project was undertaken by Dean Roscoe Pound and Professor Felix Frankfurter of Harvard Law School with the collaboration of experts in the various departments of the undertaking. Its scope and thoroughness are partially indicated by the roster of problems studied and names of investigators: Police Administration was studied by Raymond B. Fosdick, Prosecution by Alfred Bettman assisted by Howard F. Burns, the Criminal Courts by Reginald Heber Smith and Herbert B. Ehrmann, Correctional and Penal Treatment by Burdette G. Lewis, Medical Science and Criminal Justice by Dr. Herman M. Adler, Legal Education by Albert M. Kales, Newspapers and Criminal Justice by M. K. Wisehart. The report contains Dean Pound's philosophical analysis of the deep-seated causes of the break-down of criminal justice in the American city, an analysis which, with slight modifications, is applicable to every large city in the country, and which should therefore form a point of departure for any thorough-going reconstruction of criminal law and procedure. The complete report, a veritable quarry of useful information on all phases of the legal treatment of criminality, has had wide circulation both here and abroad and has already given impetus to many reforms not only in Cleveland but in other parts of the country. A permanent commission of representatives of leading civic organizations has been established and keeps continually in touch with the administration of criminal justice in Cleveland. It has already brought about great improvement in the system of record-keeping (an indispensable preliminary task in controlling the administration of justice), has raised the morale of the criminal bench, and stimulated and kept active public interest in this perhaps most important single problem in modern city life. Somewhat similar in scope and function is the Chicago Crime Commission.

Criminal Courts. — Deserving of separate mention are the unified criminal court system of Detroit and the New York State project for a ministry of justice. One of the readiest means of escape of the professional criminal, not counting the many afforded by constitutional guarantees designed for a different day, age, and type of criminal, is the dual system of criminal courts existing in most American cities, with its wasteful and dangerous duplication of machinery. So numerous and subtle are the "paths and by-paths" of procedure whereby the professional criminal with the aid of his henchmen, the disreputable bondsman and the shady lawyer, is able to escape the meshes of the law while the inexperienced and socially less dangerous first offender is caught, that the remedy of this one situation alone should materially lessen organized, large-scale, urban criminality.

This seems to have been proved by Detroit's experience. Before April, 1920, that city's criminal tribunals were divided into the usual double system of superior and inferior courts with separate prosecutory and judicial machinery,—a system having little more than historical tradition to support it. After that date there was a marked decrease in the volume of crime as reflected in the statistics. While some of the decrease is attributable to improvements in the police department, the police themselves claim that much of it is due to the unification of the courts, and consequent reduction in the number of appeals, delays, and other technical devices afforded the experienced criminal. Similar unification was recommended for the Cleveland courts, and would doubtless prove of value in most large American cities; for whatever may be society's most important aim in dealing with the offender its legal system must first be designed to give it some assured control over him.

Administration of Justice.—For a number of years American socio-legal scholars, such as Dean Roscoe Pound and Judge Benjamin Cardozo, have been urging the adoption, in the larger states at least, of a ministry of justice,—an instrumentality necessary to round out and articulate existing branches of the government. While stress has been laid in the literature upon the ministry's value to the administration of the law in general, and particularly the civil law, its usefulness in the administration of criminal justice should not be underestimated. This instrumentality is needed to provide for the continuous study of the effectiveness of the law in action as compared to the law in books; for bringing about a system of proper records as a basis of such study and of coördination of effort among the various agencies that deal with the offender; for ascertaining from judges, legal scholars, authoritative writings and such survey reports as that of Cleveland the anachronisms and wastefulness in existing legal institutions; and for bringing the law generally as nearly as is possible and desirable into harmony with the demands of the day and age.

It was largely due to the scholarship, zeal and labor of Judge Cardozo that the nearest approach ever made in this country to this much-needed reform was taken. In 1923, Governor Smith of New York appointed a commission "to investigate defects in the law and its administration." That distinguished commission unanimously adopted the report of Judge Cardozo's sub-committee, of which the principal recommendation was for the establishment of a "permanent law revision commission," very similar to the ministry of justice in its organization and in some of its proposed duties. It provided for a membership of several practicing attorneys and legal scholars to be drawn from the faculties of universities. In this manner the necessary continuous contact between the progressive agencies in the community and the governmental machinery might have been brought about through the intermediary of students of the law. Unfortunately, however, the bill was defeated, although it almost became a law.

Investigating Commission.—Among recent enterprises may be mentioned (1923) a series of sensational articles on the crime situation throughout the country appearing in a popular periodical. At the same time was announced the launching of a "National Crime Commission" apparently well-financed and having on its board of membership a number of men prominent in business and governmental circles. Several committees have been organized and the movement appears to be making considerable headway. It is to be regretted, however, that this eminent body does not as yet seem to attack the problem of criminality in its more important, fundamental implications,—namely, from the points of view of the individual and social causes of delinquency and of the fundamental philosophical inconsistencies underlying our body of criminal law.

This commission might well take a number of pages out of the remarkable report of Professor Enrico Ferri's Italian Commission for the Reform of the Penal Statutes, appointed in 1919, which attacks the problem of criminality not as exclusively a legal one, but as a socio-legal one, and which frankly uproots the traditional metaphysical basis of criminal responsibility and substitutes the scientific basis of the Positive School of Criminology. Indeed, our more enlightened Juvenile courts in this country do likewise. There is no doubt, however, that the National Crime Commission has a great opportunity for useful service both because of the far-reaching geographical extent of its operations and because it has enlisted some of the most respected citizens in the country to serve on its committees.

PREVENTIVE WORK IN DELINQUENCY

By August Vollmer

Chief of Police, Berkeley, California

Methods of Prevention.—A few centuries ago organized society employed rather crude weapons in defending persons against attacks by criminals. The ordeal, combat, and torture failed in their purpose; and within comparatively recent times the imposition of the death penalty for most crimes did not deter criminals from plying their nefarious trade.

As a result of humanitarian endeavors during the past century, the death penalty has been abolished in nearly all cases; better police methods have been introduced, criminal procedure has considerably improved, and prison reforms have been adopted by civilized countries. None of these innovations has diminished the number of criminals, or reduced crime to an appreciable degree, notwithstanding prophecies to the contrary.

Juvenile courts were created for the purpose of saving child offenders from becoming habitual criminals. After functioning for a decade or more, we learn that many of the most desperate criminals came under the benign influence of these tribunals, but continued their criminal careers when they were again turned loose upon society.

Scientific study of juvenile repeaters by eminent criminologists was introduced, and this has been extended in some cities to include all children brought before the court. These are all natural and progressive steps, and each move made contributed to human knowledge, and each step forward suggested a new and better plan for the control of crime.

Police records and the amount of space devoted to crime in the daily press and other periodicals seem to indicate that the present crime-prevention structure is inefficient, and other forces must be brought to bear upon this great social menace, otherwise the civilization of to-day will perish as other civilizations have before it.

Only catching, convicting and sending prisoners to jail for a short or long sentence does not prevent crime any more than treating malarial patients for definite periods prevented malaria. Study of the causes, and removal or destruction of these, is the only safe and sane approach to crime prevention.

Effect of Vital Human Character.—Criminology teaches that the vital organization, consisting of the circulatory, nervous, glandular and musculatory systems, regulate and control instincts, volition, intelligence and temperament. These inherent qualities, interacting with environment, which includes the home, school, church, neighborhood, companions, recreations and occupations, produce mental characteristics designated as dispositions, attitudes, habits, conscience, ideals, virtues, sentiments, likes and dislikes. A defective vital organization produces intellectual, volitional and emotional distortions. These distorted inherent qualities, interacting with environment, cause anomalies of character observable among criminals. Conversely, unwholesome environment is frequently the genesis of vice, ignorance, emotional instability, volitional irregularities, vicious habits, anti-social attitudes and dispositions, blunted conscience and perverted likes and dislikes.

Heredity and Environment.—We must know the part that heredity or environment play in shaping the destinies of those who depart from the paths of rectitude. No amount of welfare work can add one inch to the congenitally deformed arm or leg. A broken limb, however, can be quickly restored to usefulness by medical experts. Hereditary defects cannot be corrected in most cases, whereas the acquired defect may respond to scientific treatment. In dealing with anti-social persons, this lesson must be constantly borne in mind, and energies wisely directed, and not wasted in attempting the impossible. Human beings are highly complicated pieces of machinery and no unskilled person dealing with delinquents should attempt to determine whether he is confronted with a problem of defective heredity, environment, or both. Scientists are better informed regarding these difficult questions, and are rapidly improving their technique to segregate the reclaimable and worth-while from the socially malformed. Family, school, and developmental histories, field work by social workers, mental intelligence, volitional and temperamental tests, physical examinations of every conceivable character, X-rays, and other laboratory investigations are the professional tools of the worker in the field of behavior to-day, and are his aids in arriving at a proper diagnosis. Dealing with facts and not fancies, the expert is able to direct the forces organized to render welfare service, and thus save them from the pitfalls of the past and help to make more effective their unselfish and wonderfully humane work.

Individual Study.—Criminologists emphasize the importance of intensively studying individual offenders, and noting and evaluating every factor which may directly or indirectly contribute to delinquency. Merely diagnosing the delinquent as feebleminded does not satisfy them for the reason that numerous persons of feeble intellect manage to get along well outside of institutions, and are not criminally inclined. Other contributories, such for example as volitional defects, emotional instabilities, and environmental factors, must be carefully inquired into, and the part that each plays carefully weighed.

Healy, Ball, Hoag, Glueck, and others have shown in their scientific contributions that there is a close relationship between misconduct and physical and mental handicaps. Further, that the delinquents as a group are markedly inferior to others. They do not contend that all delinquents are mentally or physically inferior, but prove from their investigations that as a group they are below average; manifestly, the sooner their defects are discovered, the better it is for the community, the family, and the offenders.

Removing Defects.—Data should also be acquired showing the results of different types of treatment used to improve or remove conditions conducive to conduct disorders. Experience has shown that correcting physical or mental defects in some cases, and improving environment in others, has completely changed the personality of many juvenile and adult offenders. An incorrigible girl became quite tractable when her adenoids were removed. Criminal impulses of an adult disappeared under antiluetic treatment. Sex irregularity ceased in one case when a boy of superior intelligence was taken out of the fourth grade and coached to enter the sixth grade the following year. A juvenile repeater, always considered a hopeless case, developed into a responsible citizen when removed from the influence of a neurotic father. There are many thousands of cases where social adjustments sufficed to change the behavior for the better of persons once considered habitual criminals.

Rehabilitation of a family or individual is attended with much danger, and care must be exercised lest through unscientific methods we reap a harvest of degenerates of the Jukes type. Perpetuating the stock of insane, epileptic, feeble-minded, degenerate, delinquent or dependent persons is positively dangerous to organized society. Moreover, it is cruel to the children of such defectives. We hold these degenerate offspring of unfit persons accountable for their acts, punish them for transgressions by imprisonment or hanging, and institutionalize or ostracize them for physical, mental or moral deficiencies. Teased, criticized, or condemned for their incapacities, deprived of their natural right to enjoy life, bodies warped by malnutrition, and liberties curtailed, they lead a miserable existence from infancy until death saves them from further pain.

Punitive and Welfare Agencies.—Considering the enormous variety of factors which contribute to delinquency, it is not surprising to learn that law-enforcement officials were unable to successfully cope with the situation, or that institutions created for the purpose of raising moral standards have not stemmed the tide of degeneracy, prostitution and crime. Without their labors, however, social conditions might have become intolerable ere this.

The welfare agencies, school, health, recreational and police departments of a progressive city, recently combined forces with a view of building up the mental, physical and moral health of school children, hoping thereby to lessen moral obliquity. Similar organized agencies in many communities are willing and able to do this great work if encouraged and supported, providing their activities are properly guided and coördinated.

To direct energies into proper channels and make more effective the constructive work that welfare agencies are now doing, it is necessary that authority be conferred upon some official or group of officials, qualified by experience and training, who can obtain their support in a study and treatment of crime and its causes. Police Departments are charged with the responsibility of preventing crime; therefore it is fitting that police officials should assume this task, providing they have the proper training.

Recently Crime Prevention Divisions have been created in a few departments; and trained social workers, men and women, have been encouraged to enter this branch of the service. Their work is broad and constructive, and another step upward in the fight to minimize dependency and delinquency. Providing splendidly equipped hospitals and institutions for the socially warped indicates a high civilization, but it is more humane and much better business sense to go farther up the stream, and control, or eliminate the source of pollution, and thus remove in a scientific manner, demoralizing influences which create social and political ills and threatens the degeneration of modern civilization.

DIVISION XXIII
WOMEN'S WORK AND PROGRESS

WOMEN'S ORGANIZATIONS

By Emma H. de Zouche
Writer on Feminist and Political Topics

Origins.—The movement for women's clubs is more than half a century old. It started with Sorosis, founded in 1868 in New York City by a small group of women with Alice Cary the poetess as president. In 1889, on the occasion of the club's twenty-first anniversary, a call was issued to all known women's clubs in the country—ninety-four in number—to send delegates to the celebration. Sixty-three delegates responded, and federated in New York. Charlotte Emerson Brown, the niece of Ralph Waldo Emerson, was the first president. Succeeding presidents were Ellen M. Henrotin of Illinois; Rebecca Douglas Lowe of Georgia; Dimies T. S. Denison, of New York; Sarah S. Platt Decker of Colorado; Eva Perry Moore of Missouri; Mrs. Percy V. Pennybacker of Texas; Mrs. Josiah Evans Cowles of California; and Mrs. Thomas G. Winter of Minnesota. Mrs. Winter was appointed by President Harding to the Advisory Council of the Arms Conference at Washington, with Mrs. Eleanor Franklin Egan of Washington and New York, the writer, now dead, Mrs. Charles Edson of California, and Mrs. Charles Sumner Bird of Massachusetts, all of whom, while representing widely differing interests, were included in federated clubs.

The General Federation of Women's Clubs, Mrs. John Dickinson Sherman of Colorado, president, National Headquarters, 1734 N street, N.W., Washington, D. C., with 2,500,000 members, is today the largest individual organization of club women, and the most far-reaching through its diverse interests, in the United States. It was the first great women's club combination in this, the most organized country in the world.

The General Federation includes 50 state Federations, 5,384 individual clubs, 23 affiliated organizations, and 31 foreign clubs, making a total of 13,488 clubs. There is a movement for universal club membership in the Federation.

The purposes of the organization include neither politics nor religion, and are anti-sectarian, the delegates uniting on "such public measures as club women can agree upon, believing them above party and dealing with them as common well-being."

The Federation is focusing its full force on the Department of the American Home. Demonstrating agents are sent into the rural districts to teach the labor-saving re-arrangement of homes, the lessening of necessary steps in housework and preparation of foods, interior decoration, and other essentials to promote comfort and eliminate drudgery. The six departments, Education, American Home, Citizenship, Legislation, Foreign Affairs, and Conservation of Natural Resources, broadly cover the Federation's program.

The National Council of Women, made up of National organizations, including the General Federation of Women's Clubs, represent ten million women. Dr. Valeria Parker of New York is the President. The National Council of Women is a member of the International Council of Women, with headquarters in London, England, and with the Countess of Aberdeen, President.

The Women's Christian Temperance Union, 750,000 members, founded in 1874, elected Mrs. Ella A. Boole president at the convention in Detroit November, 1925, to succeed Miss Anna A. Gordon, who is now president of the World's Women's Christian Temperance Union. Only two women have filled the executive chair of the National organization since the death of its famous leader, Frances E. Willard, in 1898, Mrs. Lillian Stevens of Maine, and Anna A. Gordon of Massachusetts, who for twenty-one years had been Miss Willard's private secretary. The day Miss Gordon retired from the National was the forty-second anniversary of her appearance in the organization. On that occasion in the same city, Detroit, she had filled the humble position of page at an early convention. Mrs. Boole was formerly New York State president of the W. C. T. U.

The Young Women's Christian Association of the United States (National Board, 600 Lexington avenue, New York City), president Mrs. Robert E. Speer; Mrs. John French, Chairman of Executive Committee; Miss Catherine Lambert, Secretary, participates in the work of the World's Young Women's Christian Associations in establishing, developing and unifying Young Women's Christian Associations in the United States, advancing the physical, social, intellectual, moral and spiritual interests of young women.

The total membership in the National organization exceeds 556,000, of whom 110,000 are girls between the ages of 12 and 15, known as the Girl Reserves. There are regional offices in Chicago, Denver, and San Francisco; local associations are enumerated as follows: 1,000 centers and branches in 255 cities; 466 centers in 105 rural districts; 144 associations in towns; and 680 student associations.

The general Association program includes classes in bible and mission study, physical training, commercial training, language study (French, Italian, Spanish, English), domestic arts and sciences, vocational training, dramatics, trained attendance, business and parliamentary law, and current topics. Special classes are conducted in the management of cafeterias, boarding residences, housekeeping apartments, room-registries, summer camps, transient and residential hotels, vacation homes, employment bureaus, health centers, home-investigation bureaus. The needs of the community determine what activities shall be undertaken by each association.

Industrial workers, business and professional women, girls and women of foreign birth, students and younger girls are included in the membership, colored and Indian girls being among those trained. In 1925 the National Board conducted 36 ten-day summer conferences for girls in 14 states, with a total attendance of 9,385. It maintains a National Training School, 135 East 52nd street, New York, which is primarily for the training of leadership with the Y. W. C. A., and while its curriculum is built upon this basis, it also attracts women preparing for social work outside of the organization.

The National Board also maintains work in the foreign field. In November, 1925, it had 107 secretaries working in 11 countries in the Baltic States, Near East, the Orient, and South America. The official organ of the National Board is the "Woman's Press," a monthly publication.

The Young Women's Hebrew Association, founded in 1903, headquarters 31 West 110th street, New York City, 6,000 members; Executive Director, Mrs. Ray F. Schwartz; secretary, Mrs. Samuel I. Hyman. In its welfare program it largely follows that of the Y. W. C. A.

The National Council of Jewish Women, 50,000 members; headquarters, 305 West 98th street, New York City; president, Miss Rose Brenner; secretary, Mrs. Estelle M. Sternberger. The New York section of this organization, numbering 6,000, has offices at 59 West 92nd street. Mrs. Edward Josephy, president; secretary, Miss Sara Schottenfels. The program is educational and philanthropic.

The Council of Women for Home Missions, 156 Fifth avenue, New York, membership 5,000,000; president, Mrs. John Ferguson; executive secretary, Miss F. E. Quinlan.

Woman's Home Mission Society, founded in 1880, headquarters 420 Plum street, Cincinnati, Ohio; membership, 485,000; president, Mrs. Wilbur P. Thirkield; secretary, Miss May Leonard Woodruff. This and the preceding organization are concerned in relief work, prison reform, and law enforcement, as well as the regular program designated in mission work.

Women's Trade Union League, of New York City, 247 Lexington avenue; membership 500 individual, 780,000 affiliated. President, Rose Scheiderman; secretary, Mabel Leslie.

National Women's Trade Union League, 104 East 9th street, New York. President, Mrs. Maud Swartz; membership, 400 individual, and large union membership affiliated through the Federation of Labor. Both these organizations work through all channels for the betterment of women in industry.

National Council of Catholic Women, founded 1920, 1312 Massachusetts avenue, Washington, D. C. Membership, 15,000. President, Mrs. Michael Gavin of New York; secretary, Miss Agnes G. Regan. It promotes educational and welfare work for women through local organizations, and supports appropriate legislation.

State Organizations.—All the large national organizations are represented by state and some city organizations. The State Federation of Women's Clubs of New York has a membership of 400,000; Mrs. Charles Dickinson, of Binghamton, is the president. The New York City Federation of Women's Clubs, with a membership of more than 100,000, has headquarters at the Hotel Astor, New York City. Mrs. William D. Sporborg is president. Both organizations have an intensive program covering club and civic interests, literary, philanthropic, home-making, legislative. The New York City Federation maintains a business women's hotel.

Social organizations in many large cities include Junior Leagues and other groups of young women which, since the War, have developed increased phases of philanthropic and civic interests. The Colony Club of New York City, and the Cosmopolitan Club of New York City are examples of groups of notable and wealthy women and magnificent clubhouses.

Patriotic societies of women include not only women representing native states in organizations, but the descendants of war heroes of various periods. The Daughters of the American Revolution, with a membership of 202,074, president general, Mrs. Anthony Wayne Cook; secretary, Mrs. Franklin T. Shumway; headquarters Memorial Continental Hall, Washington, takes the lead in numbers. Continental Hall during the War sheltered many historic gatherings, and certain sessions of the Arms Conference were held there. The General Society, Daughters of the Revolution, founded 1891, headquarters 15 West 37th street, New York City; membership, 3,000; president general, Mrs. Charles A. Latham.

Women's City Clubs.—Since the granting of the suffrage to women, Women's City Clubs have been organized in many of the large cities of the United States.

Many wartime organizations carry on in peace in welfare and philanthropic work.

Colonial Dames of America, founded 1890; headquarters, 65 Park avenue, New York City; Mrs. Henry P. Loomis, president; Miss Anne A. Sands, secretary. Membership, 775.

National Society Colonial Dames of America, founded 1892. Headquarters, Washington, D. C.; membership, 9,000; Mrs. Joseph R. Lamar, president; Mrs. Barrett Wendell, secretary.

Both organizations keep alive the historical traditions of their country and stimulate patriotism.

American Association of University Women, founded 1882; 1634 I street, N.W., Washington, D. C., membership 20,000; president, Dr. Aurelia H. Reinhardt; executive secretary, Dr. Mina Kerr. This, like the scattering organizations of university women throughout the United States, is organized for the benefit of the college women in all walks of life. The Women's City Club of New York, No. 22 Park avenue; Mrs. H. Edward Dreier, president; membership, 2,800, is affiliated with a chain of similar clubs across the continent.

WOMEN IN POLITICS

By Emma H. de Zouche

Writer on Feminist and Political Topics

Arrival of Women.—Women at the polls were coincident with the first broadcasting of radio in the United States. These two great innovations in our national life made their début together at the presidential election of 1920.

The Socialists, the Prohibitionists, the Labor Party, and other minor parties found the influx of women no embarrassment. They had always belonged to those parties. But the Republicans and Democrats who had deprecated the inclusion of a feminine electorate until party leaders capitulated to the inevitable, accepted them on an equal footing with many hesitations. In name, but not in authority, some women held posts co-equal with men in party government; and rebellions have been frequent. But as the co-partnership grows older, there is evidence of closer harmony and genuine coöperation.

National League of Women Voters.—This independent organization was conceived to be a threat of a woman's party. The Suffragists under the leadership of Mrs. Carrie Chapman Catt, to tighten up their machinery in the last years of the struggle for the vote, followed the lines of political district organization. From them was derived the new organization which was not completed until after woman's enfranchisement. It is a non-partisan—or all-partisan, as they prefer to call it —organization, to educate women as citizens, teach them the mechanics of voting, and to get out the vote. One of the functions of the League is an examination into the policies and promises of candidates on local or national issues. A questionnaire is sent to the candidates of all parties named on the Ballot, and their replies, maintained as a record, are open to the public at the headquarters of the League of Women Voters, in city, state or county.

Open forums, at which the candidates of all parties are invited to address the public and meet their opponents, are the campaign contribution of the League of Women Voters. Men leaders of the major parties, and some of the candidates themselves, have opposed these methods as an intrusion on the rights of candidates; but the League continues this form of political information, in forty-four states, and three-fourths of the Congressional districts of the country. In many districts local Leagues print and distribute thousands of these records among the women of the electorate.

The League's citizenship schools have become a recognized system of political education. Two national citizenship schools and eighty-six State schools were reported in 1924. And the Universities of Illinois and Minnesota are among the later institutions which extend coöperation.

Non-Partisan Information. — The League of Women Voters urges all women to join the parties of their choice, but at the same time offers a middle-of-the-road organization where persons of widely differing political views may together work out common problems. Child welfare bills, and bills removing legal discriminations against women are supported in these States. Support of federal bills, in keeping with the League's program, such as the Sheppard-Towner Act (maternity legislation), and the independent citizenship of married women (both of which are now law) is authorized by the League convention. A Board of Directors, consisting of six officers and seven regional directors, conduct the work of the League. Miss Belle Sherwin is the National President, and the headquarters is in Washington.

An important Department of the work of the League, expanded from a wartime committee, is the Department of International Coöperation to Prevent War, in charge of Miss Ruth Morgan of New York, Third Vice-President. This will play a part in World Court discussions. The League's Congressional watcher on the World Court progress during the session will be Mrs. Maud Wood Park, National President for four years, and described by legislators at the Capitol as "the lady who made lobbying respectable."

National Republican Women's Association.—Republican women claim an organization thirty-two years in advance of the ballot, which was established in 1888 by Mrs. J. Ellen Foster, then rising into fame as a platform speaker for the Party, and a group of women of Congressional circles. Mrs. Foster organized branches in many states while on speaking tours about the country, and in Washington edited the organ, known as *The Home and The Flag.* Miss Helen Varick Boswell, now Associate Leader of New York county, as organizer for Mrs. Foster in the first McKinley campaign, completed a chain of these Associations which supported Republican candidates during political seasons, and in the interim became political study clubs. In the second McKinley campaign, the Republican Women's Association of New York, under Miss Boswell, and Mrs. Clarence Burns, made a house-to-house canvass of the East Side tenement house district, a Tammany stronghold—a feat of no little daring in those days—which attracted the widest attention throughout the country. With the coming of the ballot, the National Republican Women's Association dissolved, members joining the Party organization.

Officials of the Association.—The first chairman of the Republican Women's National Executive Committee was Mrs. Medill McCormick of Illinois, daughter of the late Senator Mark Hanna and wife of Senator McCormick, since dead. First appointed vice-chairman in charge of Organization was Mary Garrett Hay of New York. Mrs. Harriet Taylor Upton of Ohio later replaced Mrs. McCormick and conducted the Republican women through the Harding administration. She is succeeded by Mrs. Alvin Herts of Kentucky. Mrs. Arthur L. Livermore was the first chairman of the Republican Women's State Executive Committee of New York. She founded the Women's National Republican Club and was succeeded in its presidency by Mrs. Charles H. Sabin.

Miss Sarah Schuyler Butler, daughter of Nicholas Murray Butler, President of Columbia University, is the chairman of the New York State Republican Women's Executive Committee. The Committee is represented by The Woman Republican, a weekly political issue, with Grace Sawyer, editor.

The clubhouse in New York is notable for its old colonial furniture. Twenty-six hundred women from all states in the Union comprise the membership. Mrs. Sabin, whose husband is a financier, is a member of the National Republican Executive Committee, and is National Republican Committee woman for New York. She also sits on the State Committee, and has been recently appointed to the New York State Reorganization Commission of which Charles Evans Hughes is the Chairman.

Democratic Women's Organization.—Before the enfranchisement, Democratic women, as such, developed organizations (with a few noteworthy exceptions) only during campaign times for the support of special candidates. Since the winning of the ballot they have been active in the Party and have been allotted positions of importance. Mrs. George Bass of Illinois was the first chairman of the Democratic National Committee in Charge of the Women Voters. She ended her service after the Cox campaign of 1920. She was followed by Mrs. Emily Newell Blair of Missouri who directed the women's activities through the campaign of 1924 for John W. Davis and the National ticket, and is still in office. Mrs. Blair achieved considerable success with schools of Democracy in many states to instruct women and first voters in party principles and the use of the ballot. Miss Elisabeth Marbury, now National Committeewoman for New York, and Miss Harriet May Mills of Syracuse, N. Y., were two of the Big Four delegates-at-large from New York to the National Convention at San Francisco that nominated Cox. The Women's National Democratic Club, Inc., with headquarters at the Hotel Wellington, New York, with Mrs. Lillian R. Sire as its president, was formed in 1917. Two years ago the National Democratic Women's Club, a second organization, was established in Washington. Mrs. J. Borden Harriman is its president and among the activities at the clubhouse is the entertainment of women Democrats who are national figures.

Officials in the Democratic Organization.—Mrs. Daniel O'Day is the Associate State Chairman for New York and likewise a member of the State Charities Board. Her coworker, and Vice-Chairman, Mrs. Franklin D. Roosevelt, wife of the former Assistant Secretary of the Navy who was nominated for Vice-President of the United States on the Cox ticket, is editor of the state organ, The Women's Democratic News. The State Finance Committee includes Mrs. Charles Dana Gibson, the sister, and Mrs. Ronald Tree, the niece, of Lady Astor who, an American woman herself, set the example of wives following their husbands' footsteps, when on Lord Astor's accession to the title she entered the House of Commons as the first woman member of Parliament. Mrs. Bainbridge Colby, the wife of the Secretary of State under President Wilson; Mrs. James W. Gerard, wife of the former ambassador to Germany; Mrs. Edith P. Morgan, sister of the late Herbert Parsons, Republican Congressman; Mrs. Norman de R. Whitehouse who fulfilled a wartime mission in Switzerland for the Government, and Mrs. Frank L. Polk, wife of the Acting Secretary of State during the Wilson Administration, are among the members of this Democratic Committee.

The Woman's Party.—The Woman's Party (national) with headquarters on Capitol Hill, Washington, has as president Mrs. O. H. P. Belmont, and secretary, Anita Pollitzer. This organization founded by Miss Alice Paul and Miss Lucy Burns, became famous for its militant methods during the fight for the vote. They picketed the White House and were arrested innumerable times, some serving workhouse sentences. In politics they are independents, supporting candidates who advocate their measures, and campaigning vigorously against their opponents. Their principal activity now is known as the Blanket Legislation Bill, to remove by Federal action all discrimination against women in existing laws. This is opposed by the women of the parties who wish to accomplish the transition by state action. Miss Paul is the Legislative Chairman.

The Anti-Suffragists, as organized opposition to the woman's vote, dissolved after enfranchisement, and went into the parties, with the exception of a small group of irreconcilables.

Women in Office.—Women voters of the United States, just five years after their enfranchisement, find themselves, in the year 1925, enjoying the rights of full citizenship, with two women governors in office, three women in Congress, and 131 women in state legislatures; with a fair share of women elected officers, and women appointees in more or less important governmental posts, where they are proving themselves; with two women in the foreign service of the country; and with at least one national policy which appears to be common to the sex, regardless of party bias—peace.

Attitude on the World Court.—With Locarno as the immediate background, practically the entire force of the women of the republic is focussing on the World Court. The majority of the bitter-enders in the Wilson following, who have hitherto turned a deaf ear to all but our entry into the League of Nations, while still maintaining their own organizations, have fallen into the ranks. Great organizations of women, whose platforms eschew politics, like the General Federation of Women's Clubs with two million, five hundred thousand members, have thrown their strength to the endorsement of the project; and the demonstration of the women at the Capital when Congress opens the discussion December 17, and during the session, will be a full and free expression.

Women Governors.—The election of the two governors—Governor Nellie G. Ross of Wyoming, and Governor Miriam A. Ferguson of Texas, each a Democrat,—curiously emphasizes the surprising number of wives and widows, even daughters, who, since women's entry into the political arena, have been promoted to the man's job in public office when death or disability removes him. Governor Ross was the widow of the man she succeeded, his co-worker while in office, and pledged herself to carry out his program. Governor Ferguson fought for the place of a husband discredited, to vindicate him, and with his help has furnished the country with chapters of exciting drama throughout the first year of her administration. Charges of graft and excessive use of the pardoning power, with threat of impeachment by the legislature, have been events in the controversy. The hypnotic slogan, "Me for Ma!" is regarded as a responsible factor in the success of the Governor's campaign.

Women in Congress.—Of the three women in Congress, the two Republicans, Mrs. John Jacob Rogers of Massachusetts, and Mrs. Julius Kahn, of California, are widows whose husbands died in service. The third, Mrs. Mary Norton of New Jersey, a Democrat, was without the influence of inheritance in her campaign.

In the 67th Congress, Mrs. Winifred Mason Huck of Illinois, a Republican, was elected to fill out the unexpired term of her father, William E. Mason, representative-at-large. In the 68th Congress, Mrs. John F. Nolan of California, Republican, was elected to fill out the unexpired term of her husband who died in office. Miss Jeannette Rankin of Montana, Republican, was a Representative-at-large in the 65th Congress, the first woman to serve. Miss Alice M. Robertson, of Oklahoma, Republican, was elected to the 67th Congress. By appointment of the Governor of Georgia Mrs. Rebecca L. Felton, 87 years old, served one day in the United States Senate, succeeding Senator Tom Watson (November 21, 1922).

Women in Federal Service.—Mrs. Mabel Walker Willebrandt of California, Assistant Attorney General, widely known for work in the Prohibition violations; Miss Grace Abbott, Director of the Children's Bureau, where she succeeded Miss Julia Lathrop; Miss Jessie Dell, of Georgia, who has replaced the late Helen H. Gardner, the first woman appointed on the federal Civil Service Commission, placed in office by President Harding, are in the forefront of the country's service, shoulder to shoulder with men. Miss Dell had served the Government for twenty-five years, beginning as a clerk in the War Department, and working her way up. In 1919 she was commissioned by the Quartermaster to take charge of the Information Bureau of the Graves Registration, in Paris. A source of peculiar gratification to the women of the country is the accrediting of two of their sex to the foreign service of the United States, which now comprehends diplomatic and consular appointments. In this department of government the bars had been rigidly maintained against feminine invasion, though women had been accepted for training, and qualified for such posts. Miss Lucille Atcherson of Ohio, the first woman on the diplomatic roster, has been named Third Secretary to the Legation at Berne. She had waited three years for the honor. Miss Pattie Field, a Radcliffe graduate, now assistant consul at Amsterdam, Holland, was drafted four months after completing her course in the Foreign Service School, where she was trained with eighteen young men.

Another innovation at the national Capital which bespeaks the merit system is the appointment of Miss Mildred Reeves as secretary to the newly elected Speaker of the House, Nicholas M. Longworth. This is the first time a woman has served in that capacity. Miss Reeves had been for several years the secretary of Mr. Longworth while he was floor leader for his party in the House of Representatives, and was therefore a logical candidate.

Women in New York Service.—New York created a sensation by electing a Republican woman, Mrs. Florence E. S. Knapp, Secretary of State at the election which returned the Democratic Governor, Al Smith, for a third term. New York City was no less spectacular in electing to the Board of Aldermen, famous for its wordy fights, another Republican woman, Mrs. John T. Pratt, the wife of a banker, who will take her seat as a pioneer woman alderman with a remarkable political experience behind her. Mrs. Pratt came politically into prominence during the Harding campaign when, as vice-chairman of the Finance (Ways and Means) Committee of the Republican National Committee, her skill and vigilance rolled up unusual returns for her party. In this undertaking she traveled from one end of the country to the other. When Republican victory was assured she worked as a henchman in her assembly district to study political organization from the smallest unit. During a revolt in the district, the Fifteenth, known as the "silk stocking" because of its personnel, she threw in her lot with the regulars, became Associate Leader of the District, and in the later race for Alderman defeated James A. O'Gorman, Jr., son of Former United States Senator O'Gorman.

WOMEN IN PUBLIC LIFE

By Emma H. de Zouche

Counsellor at Law, Boston

NATIONAL LEGISLATIVE SERVICE

United States Congress.—Woman has served in Congress since the adoption of the nineteenth amendment—one in the Senate and seven in the House, as follows:

Mrs. Rebecca Latimer Felton was appointed senator from Georgia at 87 years of age, by Governor Thomas W. Hardwick, to fill the unexpired term of United States Senator Thomas E. Watson. On November 7, 1922, Walter F. George was elected Senator at the polls, but out of courtesy, he delayed his appearance at the opening session of Congress one day, in order to allow Mrs. Felton to be sworn in and take her seat. Mrs. Felton made one brief address during her term. She appeared in the Senate on November 21, 1922, and served to the end of her term, being 22 hours and 25 minutes. Miss Jeannette Rankin (Montana), Miss Alice Robertson (Oklahoma), Mrs. John F. Nolan (California) to succeed her husband, deceased, and then to a term by election.

Mrs. Winifred Mason Huck (Illinois) to succeed her father, deceased.

Mrs. Florence Prag Kahn (California) to succeed her husband, deceased, now in Congress.

Mrs. Edith Nourse Rogers (Mass.) to succeed her husband, deceased, now in Congress.

Mary T. Morton (New Jersey), now in Congress.

In the East and South, namely, New York and Kentucky, respectively, a woman was elected Secretary of State in 1925.

STATE LEGISLATIVE SERVICE

First Woman Speaker.—For the first time in its history, on February 12, 1924, the speaker's chair in the New Jersey House of Assembly was occupied by a woman, Marguerita Lost. In 1925 a woman Register of New York County was elected to the highest salaried public office a woman has ever held in this country, at $12,000 a year.

It has been estimated that in the elections in 1924 ten women were elected to the State Senates, and 128 to the lower houses of the State Legislatures. (These figures are only approximate, since it was impossible, in some instances, to obtain accurate data at the time this article was written.)

Women in the State Legislatures.—The following are the women members of the various State legislatures so far as obtainable.

(R stands for Republican. D for Democrat. The total number is 132.)

Arkansas
Erle Chambers, D.—(lower house).
Mrs. Sidney J. Hunt, D.
Mrs. Elizabeth H. Thompson, D.

California
Cora M. Woodbridge—(lower house).
Anna L. Saylor.
Esto B. Broughton.
Grace S. Dorris.
Eleanor Miller.

Colorado
Minnie Love—(lower house).
Martha Long.

Connecticut
Alice P. Merritt—(upper house).
Marjorie Cheney, R.—(lower house).
Corinne R. Alsop, R.
Mary B. Weaver, R.
Helen A. Green, R.
Edith Raymond, R.
Clarissa Nevius, R.
Helen E. Lewis, R.
Annie E. Vinton, R.
Mrs. Maud Woodward, R.
Mary M. Hooker, R.
Edna C. Fenniman, R.
Hanna D. Townsend, R.
Elizabeth W. Coe, R.
Julia Emery, R.
Sarah B. Crawford, R.
Ethel M. Ryan, R.

Delaware
Mrs. Florence M. Hanby, R.—(lower house).

Georgia
Bessie Kempton, D.—(lower house).
Mrs. Viola Napier, D.

Idaho
Anna Hanson, R.—(upper house).

Illinois
Mrs. Florence F. Borer, R.—(upper house).
Mrs. Lottie Holman O'Neill, R.—(lower house).
Mrs. Catherine F. Goode, R.
Mrs. Rena Elrod, R.

Indiana
Antoinette C. Haggenwald, R.—(lower house).
Elizabeth H. Daugherty, R.

Kansas
Lavonia N. Donica, R.—(lower house).

Maine
Mrs. Catherine C. Allen, R.—(lower house).

Massachusetts
M. Sylvia Donaldson, R.—(lower house).
Mrs. Harriet R. Hart, R.

Michigan
Mrs. Cora R. Anderson, R.—(lower house).

Minnesota
Mrs. Mabeth H. Paige—(lower house).
Hanna Kempfer.

Mississippi
Miss Beele Kearney—(upper house).
Mrs. Nellie N. Somerville—(lower house).

Missouri
Emma Knell, R.—(lower house).

Montana
Mrs. Catherine C. McCarty—(lower house).

Nebraska
Mrs. Clara C. Humphrey, R.—(lower house).
Sarah T. Muir, R.
Mrs. Mabel A. Gillespie, D.

Nevada
Daisy Allen—(lower house).
Florence Snazey.
Mayme Schwebble.

New Hampshire
Dr. Zatae Straw, R.—(lower house).
Mrs. Arnold S. Yantis, R.
Mrs. Hobart Pillsbury, R.
Mrs. Mary Chapman, R.
Mrs. Imogene V. Emmons, R.
Mrs. Marcia S. Hilton, R.
Mrs. Nellie J. Page, R.
Georgie E. Worcester, R.

Margaret H. Barden, D.
Jennie Fortier, D.
Victoria Langlois, D.
Helen J. Young, D.
Virginia P. Lunderville, D.
Katherine Donahue, D.

New Jersey
May A. Thropp, R.—(lower house).
Mrs. Lila Thompson, R.
Madge I. Ebert, R.
Mae Carty, D.
Mrs. C. Finn, D.

New Mexico
Mrs. R. W. D. Bryan, D.—(lower house).
Mrs. Charlotte A. Palmer, R.
Mrs. Louise N. Coe, D.—(upper house).

New York
Mrs. Rhoda Fox Graves, R.—(lower house).

North Carolina
Julia Alexander, D.—(lower house).

North Dakota
Minnie D. Craig, R.—(lower house).
Laura B. Sanderson, R.

Ohio
Mrs. Nettie B. Longhead, R.—(upper house).
Mrs. Maud C. Waitt, R.
Grace E. Makepeace, R.—(lower house).
Nettie M. Clapp, R.
Mrs. Clara W. Deer, R.
Mrs. Viola D. Romans, R.
Mrs. May Van Wye, R.
Mrs. Florence H. Wells.
Mrs. C. J. Ott, R.
Osa Penny, R.

Oklahoma
Mrs. Lamar Looney, D.—(upper house).
Mrs. Anna Laskey, F. L.—(lower house).
Gladys Whittet, D.
Mrs. Ida L. Robertson, D.

Pennsylvania
Mrs. Flora M. Bare, R.—(upper house).
Lillie H. Pitts, R.—(lower house).
Martha G. Thomas, R.
Helen Grimes, R.
Alice M. Bentley, R.
Maud B. Trescher, R.
Martha M. Pennock, R.

Rhode Island
Isabelle A. O'Neill, D.—(lower house).

South Dakota
Gladys Pule, R.—(lower house).
Celia M. Kelley, R.
Christine Olson, R.
Mrs. Mabel Woodie, D.

Tennessee
Mrs. W. P. Davis, R.—(lower house).
Lizzie Lee Miller, D.

Utah
Mrs. N. A. Dunyon, R.—(lower house).
Mrs. Julia Smart, R.
Mrs. Arthur E. Graham, R.
Mrs. Achsa E. Paxman, R.

Vermont
Mary J. Simpson, R.—(lower house)..
Mrs. Ina R. Niles, R.
Rev. Mabel T. Winch, R.
Mrs. Josie H. Fay, R.
Mrs. Elsie C. Smith, R.
Lillian E. Richardson, R.
Mrs. Annette Dimock, R.
Mrs. Flora B. LaMorder, R.
Mrs. Ada S. Barlow, R.
Mrs. John Taylor, R.
Mrs. Ella B. Seward, R.

Washington
Reba Hurn—(upper house).
Mrs. Belle Reeves, R.—(lower house).
Mrs. Harry John Miller, R.
Mrs. Maude Sweetman, R.

West Virginia
Dr. Harriet B. Jones, R.—(lower house).

Wisconsin
Helen M. Brooks, R.—(lower house).
Mildred Barber, R.
Helen F. Thompson, R.

EXECUTIVE SERVICE

Federal Executive Offices. — A number of women have held and are holding important Federal positions. Among these are Miss Jessie Dell, a member of the National Civil Service Commission, succeeding Mrs. Helen H. Gardner, the first woman to hold this position; Mrs. Bessie Brueggeman, Chairman of the United States Employment Compensation

Commission; Grace Abbott, Chief of the Children's Bureau of the Department of Labor, succeeding Julia Lathrop; Mary Anderson, Chief of the Woman's Bureau of the Department of Labor, where she has thirty assistants, and has the responsibility of the welfare of at least eight million working women; and Dr. Louise Stanley, Chief of the Bureau of Home Economics of the Department of Agriculture.

Other departments of the Federal Government also have women in important positions, such as Assistant United States Attorney General Mrs. Mabel Walker Willebrandt, who succeeded Mrs. Annette Abbott Adams, and who has charge of cases concerned with the enforcement of the 18th, or Prohibition Amendment. In the latter part of 1925 there were at least nine women acting as Assistant United States Attorneys.

The first woman to occupy a position in our foreign service was Miss Lucille Atcherson, who was appointed third Secretary of the Legation at Berne, Switzerland, and in October, 1925, a second woman was appointed Vice Consul at Amsterdam. Another branch of the Federal service, headed by a woman, was that of Collector of Internal Revenue of Illinois, a position which was occupied by Mrs. Mabel Reinecke.

State Governors.—Wyoming, which first gave the franchise, was the first state to be governed by a woman governor, Mrs. Nellie T. Ross, who was inaugurated as governor on January 5, 1925. She was elected with a plurality of 7266 votes.

In the same year Mrs. Miriam A. Ferguson, wife of former Governor James E. Ferguson, was elected governor of Texas by a plurality of about 75,000. She was inaugurated January 20, 1925.

Other State Offices

- Mrs. Solidad C. Chacon, Secretary of State, in New Mexico.
- Mrs. Florence E. S. Knapp, R., Secretary of State, New York.
- Mrs. Mary C. Bradford, State Superintendent of Public Instruction, Colorado.
- Minnie J. Nielson, State Superintendent of Public Instruction, North Dakota.
- Elizabeth Eckles, State Superintendent of Public Instruction, New Mexico.
- Miss Fannie Herrington, Secretary of State, Delaware.
- Annie Matthews, New York City Register, New York.
- Luella D. Richardson, unanimously elected County Treasurer of Niagara County, New York, by both parties.

Michigan has a woman member of the State Board of Agriculture. Nine states have women superintendents of education. Wisconsin has a woman on the Public Debt Commission; and Philadelphia a woman Commissioner of Public Welfare; Texas a woman on the Citizenship Commission, and other states have women state officials.

City Offices.—In this limited space it is impossible to enumerate the various offices in cities and towns, occupied by women, but it is known that at least two cities have women city managers; many western cities have women mayors; many women have been elected to the City Council boards; Health boards; School Committee boards, and Police and Fire Commissions. Prairie Home, Missouri, has the unique distinction of having its entire board of the City Council, as well as the Mayor, composed of women.

JUDICIAL SERVICE

Judge Florence E. Allen of the Supreme Court of Ohio is the first woman in the United States to attain that honor. Though a Democrat, she was elected irrespective of party, as a shining example that the judiciary is above party consideration. She had served as Assistant County Prosecutor in Cuyohoga County, and as Judge of the Court of Common Pleas of the same county prior to her elevation to the Supreme Bench. She was born in Utah in 1884 and had the practice of law not proved more alluring would have followed a musical career. She was well known as a lecturer and writer on music, a critic both here and abroad. Judge Allen advocates women in the jury box to forward the ends of justice.

Among other women judges are Catherine Sellers of the District of Columbia, the first woman to hold a Federal Judgeship; Mary O'Toole, a judge in the Municipal Court of the District of Columbia; Mrs. Violet Fahnestock, a City Magistrate of Philadelphia; Mary Bartelme of Chicago, Illinois, Judge of the Circuit Court of Cook County; Mary Grossman, a Municipal Court Judge in Cleveland; several women Probate judges in Ohio and Connecticut, and three women appointed by the Governor of Texas to the Supreme Court of that state for special cases only.

EXAMPLES OF UNOFFICIAL PUBLIC SERVICE

A Typical Political Leader.—Mrs. Carrie Chapman Catt of New York, through long service for woman suffrage, nationally and internationally, notably her leadership in the winning of the Nineteenth Amendment and its final ratification, has been called The Emancipator. While the laurels are shared by other women leaders and the suffrage army behind them, Mrs. Catt's relation to the cause gave her influence peculiar weight. She had held no office in the suffrage movement longer than the need seemed to require. An independent in politics, she has held no position under the government. Mrs. Catt was President of the National American Woman Suffrage Association from 1900 to 1903, when she made a world tour organizing the International Woman Suffrage Alliance in twenty-eight nations. It now represents the women of forty-two nations, Turkey the most recent, and Mrs. Catt, its first president, now Honorary President, has been replaced by Mrs. Margaret Corbett Ashby (Headquarters, London, England). Again elected President of the National American Woman Suffrage Association in 1916, Mrs. Catt continued in office until women had the ballot. She then founded the League of Women Voters for the education of women in citizenship; and as temporary chairman gave way to Mrs. Maud Wood Park, now president.

In 1925 in Washington Mrs. Catt brought together the All-American Union of Women, composed of women of twelve Central and South American countries, Miss Bertha Lutz, President. She presided over the "Conference on the Cause and Cure of War" in the National Capital, which aroused a sentiment for the World Court. As a speaker and lecturer she has appeared in every state in the Union, and most of the civilized countries of the world.

In addition to a series of Presidents of the United States, Mrs. Catt has personally interviewed the Presidents of Brazil, Argentina, Chile, Uruguay, and Peru on woman's equality, and has discussed with Lloyd George, the English premier, after the War, women in the diplomatic service. Mussolini, in 1923, promised her that should he remain in power he would see that the women of Italy had the municipal vote. He made a speech in the Lower House advocating this extension of the rights of women, but a move to appoint the government of the municipalities from the top has successfully blocked any progress. In France Mrs. Catt interviewed Millerand and in Germany President Ebert, now dead. During the War Mrs. Catt served in the Women's Division of the Council for National Defense, of which the late Doctor Anna Howard Shaw was chairman.

A Typical Social Leader.—Jane Addams of Illinois, a settlement worker in Hull House, Chicago, widely known as a reformer, is perhaps the woman leader of the Peace movement of the world. With Ella Gates Starr, she opened Hull House in 1889 and has since been Head Resident. She was Inspector of Streets and Alleys in the neighborhood for three years, and presided over the conference of Charities and Corrections. She is the author of many books on social conditions and reform, is chairman of the International Committee for Permanent Peace, and president of the International Congress of Women, presiding at conventions at The Hague, Zurich, and Vienna, between 1915 and 1923. She was the leader of the women in the famous voyage of the Peace Ship during the World War. She has won degrees from many colleges in the United States.

A Typical Educator.—Martha Van Rensselaer, Director of the College of Home Economics of Cornell University, has brought the American home into a College Curriculum. She was elected school commissioner when a young teacher in Cattaraugus County, New York, by unanimous vote of Republicans and Democrats, and her tours of inspection through the rural districts brought her into contact with the "soul-smearing" drudgery of the farm women. She put into execution plans which revolutionized the work of the household, cut the kitchen in half, and installed simple suitable equipment, saving thousands of steps a day. Her report to Cornell and the Department of Education first brought about courses in Home Economics at the University, later a School of Home Economics. In 1925, Miss Van Rensselaer, now a full-fledged member of the faculty, was placed in charge of the College of Home Economics of the University of Cornell. All phases of the home problem are included in the training, from the baby to the budget. To her efforts are traceable inspiration for the Better American Homes movement now sweeping the country.

WOMEN'S RELATION TO POLITICS AND GOVERNMENT

By Jennie Loitman Barron
Counsellor at Law, Boston

CONSTITUTIONAL CHANGES

At the end of each year it is the custom of the world to count gains and losses. The following is a balance sheet showing the progress of women in governmental activities for five years, beginning with their enfranchisement on August 26, 1920, through the ratification of the 19th Amendment to the Constitution of the United States. On August 26, 1920, ended the long struggle which began when American women sent a petition to Congress in 1776 and demanded the right to vote equally with the men, which right was promptly denied them. Out of 36 states necessary for ratification, 35 had accepted the amendment by March 22, 1920, 25 having ratified in special sessions, and 10 in regular sessions. Tennessee, in August, 1920, was the 36th state to ratify the 19th Amendment.

The granting of the franchise to women made them eligible in most of the States to all elective and appointive offices. In a few states, however, the legislatures passed specific laws which made women eligible to hold office. In most of the States where the word "he" in the statute law has been interpreted, the interpretation has been favorable to the eligibility of women for such offices, but there are still one or two states where there has been no interpretation of this word.

CITIZENSHIP WORK

Practically every woman's organization today has a Civics or Citizenship department. The National League of Women Voters has a department of efficiency in government and training of women in citizenship; and a committee on the legal status of women, which seeks to remove legal discriminations against women by providing specific remedies for specific wrongs. In addition to the formed organizations, the Democratic and Republican Parties have done a great deal of work in organizing and training women for citizenship. They have held hundreds of citizenship schools throughout the nation, and have trained large numbers of women speakers for political work. These major parties have established women's branches in all the larger districts throughout the country where partisan elections are held.

POLITICS AND PARTIES

Parties. — The National Woman's Party's program is its "blanket bill," which is designed to remove all legal discriminations against women in the forty-eight states, by securing a national constitutional amendment.

Commissions.—In order to further National Legislation of interest to women, at least fourteen national organizations formed the Women's Joint Congressional Committee. This committee maintains a lobby of women. These organizations are: American Association of University Women; American Home Economics Association; General Federation of Women's Clubs; Girls Friendly Society of America; National Congress of Mothers and Parent Teachers Associations; National Consumers' League; National Council of Women; National Council of Jewish Women; National Federation of Business and Professional Women; National League of Women Voters; National Women's Christian Temperance Union; National Women's Trade Union League; National Board of Young Women's Christian Association; Service Star Legion.

Elections. — Women have participated in two Presidential elections, namely 1920 and 1924. In 1924 women were officially recognized by the various political parties, and accorded equal representation with the men from each state on the national committees.

Conventions.—The Republican National Convention convened June 10, 1924, with 425 women delegates and alternates present. For the first time a woman was elected chairman of a committee on political organization, and introduced the chairman of convention; and eight women were put on the Executive Committee.

The Democratic National Convention convened in New York on Saturday, June 24, 1924, with 476 women delegates and alternates. The National Committee appointed women on the advisory committee to meet before the convention, and adopt proposals for the platform. They had a woman chairman of the credentials committee, and one was proposed as a Vice Presidential candidate, while several women seconded the nomination of men Vice Presidential candidates. The Prohibitionists went so far as actually to nominate a woman as Vice President.

In the National Conference for Progressive Political Action, held in Cleveland, July 4 and 5, women received great recognition. And the Socialist Party throughout 1924 had a woman Executive Secretary.

Mrs. Emily Newell Blair is, at the present time, Vice Chairman of the Democratic National Committee, and Mrs. A. T. Hart of Kentucky, a Vice Chairman of the Republican National Committee, succeeding Mrs. Harriet Taylor Upton.

Measures Urged by Women.—Among the important measures which have been urged by women citizens through organizations, in the five years since their enfranchisement, have been the following:

A Department of Education, with its chief a member of the Cabinet; ratification of the Child Labor Amendment, limiting and regulating the conditions under which children shall work; a Uniform Marriage and Divorce law; the Fess Amendment, which would increase appropriations for training in home economics; World Peace; bills making women eligible and liable for Jury Service; bills requiring equal pay for equal work, regardless of sex; the Sheppard-Towner Law; the Cable Bill; Child Welfare and Public Health measures; removal of legal discriminations against women, and various other social measures in government.

The Sheppard-Towner Law was a measure proposed to improve, through a combination of Federal and State aid, the physical welfare of mothers and new born babies. Women were largely responsible for having made permanent the Women's Bureau of the United States Department of Labor. Woman's organizations also assisted greatly in securing a bill for reclassification of the Federal service, a measure which embodied the principal of equal pay for equal service in government, irrespective of sex.

EQUAL RIGHTS AMENDMENT

Program.—After the passage of the Woman Suffrage Amendment to the United States Constitution the National League of Women Voters, which was practically an offspring of the National Woman Suffrage Association, and the National Woman's Party, proceeded with a program which included the removal of all legal discriminations against women.

The campaign was undertaken by both organizations in the states. The National Woman's Party, however, in November, 1922, in addition to its state work, decided to work for the adoption of a Federal Amendment to effect the same end.

Lucretia Mott Amendment.—In July, 1923, at its National Convention, it adopted the present draft of the Lucretia Mott Amendment, which reads as follows: "Men and women shall have equal rights throughout the United States, and every place subject to its jurisdiction. Congress shall have power to enforce this article by appropriate legislation." This amendment was introduced in the Senate on December 10, 1923, by United States Senator Charles Curtis, from Kansas, Republican, and on December 13, 1923, in the House, by United States Representative Daniel R. Anthony of Kansas, Republican. It was known as Senate Joint Resolution No. 21 and House Joint Resolution No. 75.

Act Secured.—The measures were referred, respectively, to the Senate and House Judiciary Committees. The measures have never come up for a vote. December 8, 1925, the second day of the session of the 69th Congress, the measure was again introduced by Senator Curtis in the Senate, and Representative Anthony in the House. It is now before the Judiciary Committee of each branch of Congress. Through this amendment the National Woman's Party aims to establish equality between men and women by one piece of legislation, which shall free all women from the effect of National or State laws discriminating against them.

OPPOSITION TO BLANKET LEGISLATION

Propaganda.—October 11, 1923, a letter, opposing the Equal Rights or Blanket Constitutional Amendment, was sent to every member of Congress. This letter was signed by a representative of the following organizations: American Association of University Women; Girls' Friendly Societies; Industrial Department, National Building, Y. W. C. A.; National Consumers' League; National Council of Jewish Women; National League of Women Voters, and National Women's Trade Union League.

Among other organizations opposing the Amendment are: American Federation of Labor, American Home Economics Association, General Federation of Women's Clubs, National Council of Catholic Women; Medical Women's National Association.

Arguments.—The following extracts from this letter state the position of these organizations: "The organizations represented below are opposed to this measure because we are advised by many of the ablest constitutional lawyers in the United States that:

"1—Existing inequalities of laws affecting men and women as such are so complicated in character, that only specific legislation can reach them effectively. Therefore, blanket legislation would be futile.

"2—The Amendment the National Woman's Party proposes would endanger existing statutes providing a 48 hour week, 8 or 9 or 10 hour day, and other industrial legislation governing the employment of women; mother's pension law; penalty for rape; and various other laws applicable or necessary to one sex, but not to the other.

"We advocate, and our organizations have been instrumental in securing in many states, the enactment of separate laws for the removal of social and economic injuries to women—laws specific in character to remedy specific evils. We believe that blanket legislation, attempting to cover all such questions, may aggravate existing inequalities or substitute new ones."

University Women. — Since 1923 the American Association of University Women have had in operation a committee to study the situation. This committee has recommended that the American Association of University Women take no action at present, for or against the amendment, but continue the investigation, and this committee also recommends that all the organizations, both for and against the amendment, meet in order that the most effective method may be ascertained of accomplishing the end for which all the organizations stand, namely, the removal of all legal discriminations against women.

Question of Equal Rights.—Some of the proponents contend that the passage of the amendment would restore to women "freedom of individual contract."

It is contended by the opponents that the words "equal" and "rights," which are used in the amendment, are capable of interpretation in many ways, and that the passage of the amendment would, therefore, involve long drawn out litigation, with the suspension, in the meantime, of laws benefiting women. Texas, Maryland, West Virginia, South Carolina and Virginia are some of the states which have defeated the blanket bill presented to the State Legislatures.

Relation to Labor.—The proponents of the measure state that the amendment "would not affect existing labor legislation," except to establish the principle that protective legislation should apply to all workers, both men and women, in any given occupation, and not to women workers alone. They state that laws which regulate the conditions of labor of women only, and not of men, often prevent women from securing employment and promotion, and that the speediest way of emancipating women is through a Federal Amendment. They also urge that a Federal Amendment would be far more difficult to change or repeal than would a state law.

JURY SERVICE FOR WOMEN

Present Status.—Women are eligible for Jury Service in 21 states in the union, namely: Arkansas, California, Colorado, Delaware, Iowa, Kansas, Kentucky, Louisiana, Maine, Michigan, Minnesota, Missouri (limited jury service only), Nevada, New Jersey, North Dakota, Ohio, Oregon, Pennsylvania, Utah, Washingtan and Wisconsin.

In several of these states women became liable for jury service through the passage of the 19th Amendment, inasmuch as the term "citizen," "qualified voter," "elector," or a like term is used in these states as the qualifications making a person liable for jury service.

Exclusions.—In 22 states the word "male" qualifies a "juror." In Kansas, Utah, Washington and Colorado, there is express provision for women jurors. In those states where the laws do not expressly provide for women jurors, nor expressly prohibit them from serving, some of the attorneys general have held that women are eligible for jury duty, the New Jersey Attorney General stating "The 19th Amendment to the Federal constitution supersedes any inconsistencies in the state constitution or law." Nevertheless, in other states a number of attorneys general have interpreted the statute to restrict women from serving on juries. For example, in Delaware and Massachusetts, although the qualifications for serving on juries are "persons qualified to vote," the attorneys general in the respective states have held that women are not eligible.

Reasons for Exemption.—In New York, Massachusetts, Connecticut, and other states, bills have been presented to the respective Legislatures making women liable for jury service, with certain exemptions, but to date they have failed of passage. However, proponents of this measure are continuing their campaign. The exemptions in these bills are, for the most part, the same exemptions as are given to men with additional exemptions to women nurses; women nursing sick members of their own families and mothers of young children. Women regard jury service as an incident of citizenship, and are urging it both as a matter of justice, and also because they believe that women jurors will improve the administration of justice.

The proponents of the measure argue that the right of trial by jury was intended to give every citizen a trial by an *impartial* jury and judgment by one's *peers*, and that a woman on trial is not receiving a trial by an impartial jury and judgment by one's peers when women are excluded from the jury box; that a jury should represent a cross section of the community, and no cross section of the community is complete without women; that women are especially needed in cases involving women and girls, and in cases affecting public morals.

CABLE ACT FOR CITIZENSHIP AFFECTED BY MARRIAGE

Agitation.—One of the outstanding examples of the change in the laws affecting the citizenship of women is the Cable Act, which was approved on September 22, 1922, and which was the result of an active campaign waged by women voters. Prior to the passage of this law, it was axiomatic that a woman's citizenship followed that of her husband. Mrs. Maud Howe Elliott, the American born daughter of Mrs. Julia Ward Howe, is an example of an American woman who lost her citizenship in 1896 through her marriage to an Englishman. On June 16, 1923, because of the enactment of the Cable Act, Mrs. Elliott was able to regain her own nationality.

Outline.—Briefly, this act provides that:—

1—An American woman citizen does not lose her citizenship upon marriage to an alien.

2—An alien woman does not gain citizenship upon her marriage to a citizen.

3—An alien woman whose husband becomes naturalized after September 2, 1922, does not gain her citizenship through her husband's naturalization.

4—A woman whose husband is not eligible to citizenship, such as a Japanese or Chinese, shall not be naturalized during the continuance of the marriage status.

Inequalities Remaining.—The citizenship rights, established between men and women, however, are not made entirely equal, inasmuch as an American man who marries a woman ineligible to American citizenship, continues an American citizen, although the converse is not true. Also, if a native American woman citizen, married to a foreigner, lives abroad continually for five years, or lives for two years in the foreign country of which her husband is a citizen, there is a legal presumption that she is no longer an American citizen, unless she takes affirmative action to overcome this presumption. The converse, however, is not true; a native American man citizen married to a foreign woman is still presumed to be an American citizen under the same circumstances.

Difficulties have arisen, through the passage of the law, since alien women from certain countries forfeited their native citizenship upon their marriage to an American, although they did not acquire their husband's citizenship. Such women have been called "women without a country." There are other foreign countries which allow her to retain her own citizenship in case she marries a man whose citizenship is not acquired by her upon marriage. Among such countries are France, Lithuania, Poland, Italy, Switzerland and Denmark. Germany, Sweden and Finland are among the others which do not allow women to retain their native citizenship upon marriage to an American citizen, but who do issue special travel papers in the event of travel.

Advantages to Women.—Inasmuch as several states make citizenship a condition precedent to obtaining Mothers' Pensions, Husbands' Homesteads, or Municipal Employment, alien widows, whose husbands were American citizens, have been deprived of these benefits even when all the children are American born. An alien woman wishing to accompany her husband, who is an American citizen, on a trip to a foreign country is refused a passport on leaving the country and cannot return with safety, or without encountering the difficulty of classification under the quota laws of the Johnson Immigration Bill. It has been suggested that the Cable Law be changed so as automatically to confer upon the wife of a naturalized citizen all the rights of citizenship, except that of the franchise.

OCCUPATIONS AND CONDITIONS OF WOMAN LABOR

By Mary Anderson

Director of the Women's Bureau, Department of Labor

Sources of Information.—The subject of woman labor gains increasing attention with each passing year, as more and more women enter the field of gainful employment and as they engage in a greater variety of occupations. Every man, woman, and child in the country is, to some extent, dependent upon the work of the more than eight and a half million wage-earning women, employed in all but 35 of the 572 occupations listed by the U. S. Bureau of the Census for 1920. In any consideration of the numbers and occupations of women workers at the present time it is necessary to resort to the census of that year since no later data which are at all comprehensive are available. A discussion of the occupations and conditions of woman labor in the United States for the year 1925, as separate and distinct from the preceding years, is out of the question.

This fact is evident from the information furnished by the Women's Bureau of the U. S. Department of Labor, an agency especially appointed by Congress to collect and disseminate data concerning wage-earning women. In view of the vast number of women workers and the great variety of their jobs and in view of the bureau's limited personnel and funds, this organization can consider for any one year only a few of the many problems pressing for attention and can investigate only a part of the field placed under its supervision. However, a survey of the publications and activities of the bureau for the year 1925 is perhaps the best way of giving a picture of the situation in regard to women workers. Even then the picture is not a clear-cut one for a definite year, but rather a panoramic representation of conditions for the 5-year period 1920 to 1925.

Two publications in 1925 are noteworthy: *Facts About Working Women*, and *Occupational Progress of Women*, the latter antedating the first by several years. Each is an analysis by the Women's Bureau of 1920 census figures; they are extremely enlightening in regard to the types of occupations in which women are engaged, their occupational progress during the several decades, and the kinds of women found in the wage-earning ranks.

General Fields of Occupation.—Try as you will you cannot get away from the woman worker; she is everywhere, and everywhere she is doing useful, important work. Statistics are not a popular way of giving information, but often they serve as a necessary skeleton on which to hang more graphic statements.

The general types of work done by women and the numbers in each broad occupational classification are listed by the 1920 census as follows: domestic and personal service, 2,186,924; manufacturing and mechanical industries, 1,930,341; clerical occupations, 1,426,116; agriculture, forestry, and animal husbandry, 1,084,128; professional service, 1,016,498; trade, 667,792; transportation, 213,054; public service (not elsewhere specified), 21,794; and extraction of minerals, 2,864.

Because of their size these figures are arresting, but perhaps of greater interest are some of the details behind this general list. Having finally blazed the trail of remunerative employment outside the home, women have stopped short at practically no type of work although many of the jobs which they perform are similar to tasks that women had for ages been responsible for in the home. Now that we have outlived the era when the slogan, "Woman's place is in the home," was at the height of its popularity, women are found in occupations which not so long ago were unheard, or undreamed of, as possible and practical ways for women to earn a livelihood. Four or five decades ago the girl in business was a curiosity, a woman doctor or lawyer was an object of prejudice, and the woman professor was scoffed at as a bluestocking. In this country to-day are thousands of women in such vocations.

There are even women who are managers and superintendents of factories, bankers and bank officials, chemists, clergymen, judges, inventors, engineers, and architects. There are women chauffeurs, draymen, teamsters and expressmen, garage laborers, switchmen and flagmen on steam railroads, ticket and station agents, telegraph messengers, steam and street-railway laborers, and large numbers of women working as telephone and telegraph operators.

Greater numbers of women are in other ranks, working in factories manufacturing cloth, garments, shoes, cigarettes and countless other articles. The overalled woman with grimy hands, making guns and shells, was a conspicuous person during the war, but she has been more or less forgotten since, and not everyone knows that she has not given up her factory work but is probably busy now producing implements of peace, while she still wears the overalls and works on the same kind of machine that she used for making guns and shells. In almost every factory where men work there are some women employed, but in some kinds of establishments there are many more women than men. In the clothing factories, where corsets, gloves, shirts, collars and cuffs, and other articles of clothing are made, and in knitting and silk mills, there are employed nearly twice as many women as men.

Increase of Women Workers.—In all general divisions of occupations other than agriculture and domestic service, women have increased in number since 1910. In clerical occupations they were nearly two and one-half times as numerous in 1920 as in 1910, as they were also in the extraction of minerals, though the number in the latter industrial group was small; the number in transportation had doubled; those in trade had increased 42.7 per cent.; and those in professional service 38.5 per cent. In domestic and personal service there was a great decrease in both the number and proportion of women so occupied. Not all Americans know that farm labor is the occupation in which more women are engaged than in any other except domestic service, yet according to the census figures this condition has prevailed in the United States for at least 40 years. However, the number of women in agricultural pursuits in 1920 had dwindled considerably as compared with the number in 1910, a diminution partly, but by no means entirely, explainable by the change in census date.

Comparison with Male Labor.—Women as wage-earners are the object of more attacks and more concern than are men. In civilized ages men have always been the accepted breadwinners, but until recent years the phenomenon of women serving in such capacity was more unusual. Woman's assumption of the breadwinning rôle has naturally stirred up much discussion. Since women have another important rôle to enact,—that of home maker and mother, since they are producers not only of economic goods but of future citizens, much interest attaches to certain personal facts about them as wage earners.

A little over one-fifth of the women, as compared with approximately four-fifths of the men, are gainfully employed. Also, one in every five workers is a woman. The comparison of their occupational distribution with that of men shows that in agricultural pursuits, in manufacturing and mechanical industries, and in transportation, the great majority of the workers are men, that is, four-fifths or more in each case. Domestic service shows a larger proportion of women—two-thirds of the total number of workers—than of men. In clerical service and in professional service the women, constituting not far from one-half of the workers in each group, almost equal the men.

Ages.—Analysis of the woman workers in regard to age reveals that it is not only young women but those of all ages who are employed. One-fifth of the women workers are under 20 years of age, two-fifths are under 25, two-fifths are 25 and under 45, and a little less than one-fifth are 45 years of age or more. Two-thirds of the women in transportation, three-fifths in clerical jobs, nearly one-half in manufacturing industries, and practically two-fifths in agricultural pursuits, in the trades, and in the professions are less than 25 years of age, in contrast to the one-fourth of those in domestic service who were as young as that. In fact, three-fourths of the women in the latter occupational group are 25 years and over, and nearly one-third are 45 or more.

Married Women Laborers.—A contrast of the ages of men and women workers shows that whereas one-fifth of the women are under 20, only one-tenth of the men are as young as that, and only a little over one-fifth of the men as contrasted with two-fifths of the women are under 25 years of age. The theory that girls are only transients in the world of employment, that they leave such occupations when they marry, is being discredited in the face of facts. The truth is that a number of women workers never marry but continue in gainful occupations for 40 or 50 years. Furthermore, many married women continue to work after marriage, in the majority of cases from economic necessity. According to the 1920 census there are two million married women; that is, 9 in every 100 married women in the country are employed in remunerative occupations. It must be pointed out that the census publications class widowed and divorced women with single women, so that it is not possible to ascertain the total number of women workers who are or have been married. It is of interest at this point, therefore, to quote from a 1925 report of the Women's Bureau which contains an analysis of census figures in four selected cities — Jacksonville, Fla.; Wilkesbarre, Pa.; Butte, Mont.; and Passaic, N. J. The data show that of the approximately 40,000 wage-earning women in these cities, 21,000 or about 55 per cent. may be designated as matrons, that is, those who were married, widowed, separated, or divorced. Over three-fifths of these 21,000 were living with wage-earning husbands, and over one-half of the matrons had children, two-fifths of the mothers having children under 5 years af age.

Because of the prejudice existing in some quarters against the married woman worker, it is significant to consider their occupational distribution. One-third of the married women are in domestic service, one-fourth in manufacturing and mechanical industries, one-fifth in agricultural pursuits, 8 per cent. in trade, about 7 per cent. in clerical service, and a little over 6 per cent. in the professions. Since over three-fourths of the married women are found in manufacturing, domestic service, and agriculture—types of work in which women have almost no opportunity for a career—it would appear that economic necessity, and not the desire to escape household drudgery, is responsible for their gainful employment. In fact, investigations have revealed that the married woman worker usually performs her household tasks in addition to her remunerative job.

Special Legal Protections.—It has been the duty of the Women's Bureau, in the interest of health measures for women workers, to study the problems surrounding their employment and to draw up standards designed to make such employment safe for women. These standards may be outlined briefly. The 8-hour day, Saturday half-holiday, one day of rest in seven, adequate time allowance for meals, rest periods at stated intervals, and the prohibition of night work are the hour standards adopted. A living wage without discrimination because of sex is the recommended wage standard. The workroom conditions advocated include: clean workrooms; lighting without glare; adequate ventilation; cool and accessible drinking water, with individual drinking cups or sanitary bubble fountains; washing facilities with hot and cold water, soap, and individual towels; an adequate number of clean, accessible toilets (one seat to every 15 women); cloak rooms; lunch rooms; and rest rooms. For correct posture at work it is recommended that seats have backs and foot rests and that they be adjusted to fit the machine and worker; also that, where possible, seats be so adjusted to machines and worktables that workers can sit or stand at work. Careful protection from machinery risks, from danger of fire, and from exposure to dirt, fumes, and other occupational hazards is also recommended. The prohibition of home work is another standard. In administration it is recommended that there be provided a satisfactory personnel department to have charge of employing and discharging, that there be competent women with responsibility for conditions affecting women workers, and finally that coöperation of these workers be secured in establishing standards.

These policies are urged not only in behalf of health but of efficiency. It pays to have good conditions of work. Nevertheless, although the foregoing standards are not difficult to attain, and although a number of progressive managers have incorporated them in their industrial program, many other employers of women, either from ignorance, indifference, or conservatism, linger behind in the march of progress and subject their employees to conditions menacing to good health and good business.

Need of Improvement.—As long as any women work in plants grimy with accumulated dirt, strain their eyes because of glare or insufficient light, stand all day or sit continuously in a cramped position; as long as their safety is jeopardized because of unguarded machinery or lack of protection against fire; as long as health is menaced by such things as the common drinking cup and the common towel; as long as one toilet must serve for 50 or more women; as long as employees must run the risk of having their wraps ruined or stolen or must eat their lunches amid the debris on their worktables, or must lie on the floor of the toilet room when ill for lack of proper service facilities—conditions which still exist in a surprising number of plants throughout the country—then not only is national pride in working conditions out of the question but definite action for improvement is called for. Wrong conditions of employment for women mean insufficient strength for bearing children and insufficient time to care for them. The sequel of this situation is the inevitable weakening or crippling of the nation. Evils of this sort are insidious rather than obvious. The health of women is in the final analysis the keystone in the tower of strength of the Nation.

Hours of Labor.—More concrete information on the hours, wages, and working conditions of women in a few States in the country are contained in reports published by the Women's Bureau during the year, 1925. For example, in one report are found data for a week in September, 1922, on scheduled hours, obtained by the Women's Bureau in 13 States and 2 additional cities—Alabama, Arkansas, Georgia, Indiana, Iowa, Kentucky, Maryland, Missouri, New Jersey, Ohio, Rhode Island, South Carolina, Virginia, Chicago, and Philadelphia — covering altogether 162,792 women employed in 1,709 stores, factories, and laundries. Over one-third of those for whom scheduled daily hours were reported had a 9-hour day, and almost one-fifth were on a schedule of 8 hours or less. These figures should not be taken to indicate anything like uniformity throughout the States included, the standards of some States being widely different from those of others. At the foot of the list stand South Carolina with over four-fifths (84.3 per cent.) of the women employees reported as working regularly 10 hours a day and Georgia with a third employed on a 10-hour schedule and almost 30 per cent employed for more than 10 hours. As representative of a higher standard are Iowa with 36.8 per cent. of the women reported working on a schedule of 8 hours or less and Maryland with practically one-third of the women included so classified. In Ohio and Missouri, although the short day was not so common as in Iowa and Maryland, it was more frequently practiced than in any of the remaining States surveyed.

A 50-hour week was the standard for the largest group of women when the workers of all the States surveyed were considered together. One-third of all women had a scheduled week of 48 hours or less; Rhode Island, New Jersey, and Maryland took the lead with approximately 68 per cent., 55 per cent., and 52 per cent. of the women reported in each, respectively, showing such a schedule. An over-whelming majority of the South Carolina workers, on the other hand, regularly put in more than 54 hours a week while in both Georgia and Alabama practically two-thirds of the women reported had a scheduled week of more than 54 hours.

Holidays.—The figures obtained in the States included indicate clearly the prevalence of a Saturday afternoon holiday in the factories. Over 95 per cent. of the women reported in the manufacturing industries had a shorter day on Saturday than on the other days of the week. Only about four-fifths of the laundry workers had a short Saturday. While the habit of keeping stores open for Saturday evening shopping has at least practically disappeared in the cities, it still remains in smaller places, and practically three-fifths of the women employed in the general mercantile and 5-and-10 cent stores had longer hours on Saturday than they had on other days. In general, satisfactory allowance was made for the lunch period. Only 1 per cent. of the women surveyed had no regular lunch time or had a period of less than 30 minutes.

Night Work. — Very few night workers were employed in the plants reporting; in fact, less than 2,000 women, who were found in 51 different plants. The largest proportion of the night workers were employed in the textile industries, and their most usual schedule of work was 11 hours a night.

Need of Legislation.—Although in each State included there were progressive employers who stood out for the maintenance in their plants of hour schedules in advance of the legal standards, there were, nevertheless, in the various States a considerable number of employers who adhered in their hour schedules for women to the daily and weekly maximum permitted by law. It is evident, therefore, that more progressive legal standards are necessary in the great majority of the States surveyed to insure all women in industry against an overlong working day.

Variation Among States.—A matter of considerable interest in connection with wage-earning women is the great variation in the labor laws for these workers in the different States. In all, 43 States, the District of Columbia, and Porto Rico have laws regulating the number of hours women may be employed, showing that the tendency to safeguard women in the interest of the home and the family is almost nation-wide. A much greater effort, however, is necessary to make industry safe for women. In many States the number of industries or occupations coming under the law is so limited as to affect only a small proportion of the wage-earning women in the State. Moreover, only 12 States—Arizona, California, Colorado, Kansas, Massachusetts, Montana, Nevada, New Mexico, North Dakota, Oregon, Utah, and Washington—the District of Columbia, and Porto Rico limit the number of hours of women employees in some industries to 8 hours a day or 48 hours a week. Night work for women is prohibited to some extent in 16 States—California, Connecticut, Delaware, Indiana, Kansas, Massachusetts, Nebraska, New Jersey, New York, North Dakota, Ohio, Oregon, Pennsylvania, South Carolina, Washington and Wisconsin—and Porto Rico. About one-fourth of the States have laws either prohibiting or regulating home work. Women are in positions of authority in the State departments of labor in 15 States and in minor positions in 19 States for the purpose of looking after the interests of wage-earning women.

Wages.—Comprehensive wage data for women workers for any one period are not available However, figures which have been collected by the Women's Bureau in 14 State investigations of women's earnings in factories, stores, and laundries—surveys made during the past 5 years—show very definitely that although some women workers are paid a fair return for their labors, thousands fail to receive a living wage and are forced to eke out an existence, often doing without the barest necessities of life. Of all the States in which surveys have been made, Rhode Island showed the highest wages, if median earnings are used as a measure The median of week's earnings of 7,780 Rhode Island women whose earnings were recorded was $16.85; that is, one-half of these women earned more than this sum and one-half earned less. The survey in this State, however, was made in 1920 when wages were uniformly high as the result of the war activities, and are not representative of the present time.

A study of the wages of 4,138 women in Kansas in 1920 showed a median of only $11.95. The median of week's earnings of 6,666 women included in the Georgia survey in 1920 and 1921 were $12.95, this period covering the time when wages were at the peak as well as the beginning of the industrial depression of 1921. The figures for the two studies made entirely in 1921 are probably affected to some degree by this slump; the median for 7,426 women in Kentucky was $10.75, and the median for 8,595 women in South Carolina was $9.50. For the five studies conducted in 1922 the medians varied as follows: $14.95 for 34,655 women in New Jersey, $13.80 for 30,568 women in Ohio, $12.65 for 15,364 women in Missouri, $11.60 for 1,793 women in Arkansas, and $8.80 for 4,868 women in Alabama. No wage studies were made by the bureau in 1923 and only two in 1924—one in Oklahoma which included 3,452 women and showed a median of $13, and one in Delaware covering 2,995 women whose median was $11.05. In 1925 two State studies of wages have been completed. The first was made in Mis-

TABLE.

Occupations in Which 50,000 or More Women 10 Years of Age and Over Were Employed in 1920 and Number of Women Employed in Each, 1920 and 1910.*

Occupation	Number of Women 10 Years of Age and Over Employed in—	
	1920	1910
Farmers, general farms	247,253	257,703
Farm laborers, general farms †	788,611	1,514,107
Dressmakers and seamstresses (not in factory)	235,519	447,760
Milliners and millinery dealers	69,598	122,447
Semi-skilled operatives:		
Cigar and tobacco factories	83,960	71,845
Clothing industries	265,643	237,270
Food industries	72,402	36,600
Iron and steel industries	57,819	23,557
Shoe factories	73,412	59,266
Cotton mills	149,185	140,666
Knitting mills	80,682	65,338
Silk mills	72,768	50,360
Woolen and worsted mills	61,715	52,056
Telephone operators	178,379	88,262
Clerks in stores ‡	170,397	111,594
Retail dealers	78,980	67,103
Saleswomen (stores)	356,321	250,487
Musicians and teachers of music	72,678	84,478
Teachers (school)	635,207	476,864
Trained nurses	143,664	76,508
Boarding and lodging house keepers	114,740	142,400
Housekeepers and stewardesses	204,350	173,333
Laundresses (not in laundry)	385,874	520,004
Laundry operatives	80,747	76,355
Nurses (not trained)	132,658	110,912
Servants §	1,012,133	1,309,549
Waitresses	116,921	85,798
Bookkeepers and cashiers	345,746	183,569
Clerks (except clerks in stores)	472,163	122,665
Stenographers and typists	564,744	263,315

---

* Because of differences in the occupation classification used by the Census Bureau in 1900, it was not feasible to include the 1900 figures in this table.

† Includes farm laborers (home farm) and farm laborers (working out).

‡ Many of the "clerks in stores" probably are "saleswomen."

§ Includes chambermaids, cooks, ladies' maids, nursemaids, bell girls, chore girls, etc., and other servants.

sissippi during January and February and comprised only 2,136 women, the median for this group being $8.60. A similar investigation was made in Tennessee in the spring. Wage records collected for 14,642 women revealed a median of $11.10.

Government Publications.—In addition to the publications already referred to, the Women's Bureau during 1925 has published or sent to press several other reports of considerable interest. One of these deals with the home environment and employment opportunities of women in coal-mine operatives' families; the immediate source of this information was the material collected by the U. S. Coal Commission in 1922-1923. Another report entitled *The Effects of Applied Research Upon the Employment Opportunities of American Women* contains descriptions of conspicuous changes which have occurred in such opportunities in certain industries as a result of the application of scientific research in the industrial field. A third study consists of a discussion of women workers in the fruit-growing and canning industries in the State of Washington, the field investigation of which was made in the summer of 1923. Other studies of significance which have been handled by the bureau during 1925, but the reports of which have not yet been published, are as follows:

Absenteeism of women in textile mills.
The status of women in the Government service in 1925.
Women who toil at night.
Industrial accidents among women.
Trend of employment among women.
Minimum wage laws.
Effects of special legislation upon women.

It is also important to call attention to the survey of foreign-born women in industry, the field work of which has very recently been completed.

This survey was undertaken at the urgent requests of organizations and persons interested in the establishment of greater opportunity and better understanding of American life among the foreign-born population of the United States.

Women's Bureau. — That the Women's Bureau has been unable to collect during any one year extensive material on all subjects which come under its supervision has been due to the fact that it has been limited in appropriation and personnel. That it has been able to accomplish as much as it has in its brief history is due partly to the aid of the organizations of interested women in all parts of the country desirous of bettering conditions for women workers, to the assistance of State authorities, and to the coöperation of employers through whose efforts the collection of data, in so many instances, has bee made possible.

WOMEN'S WORK FOR PEACE

By Ruth Morgan

Chairman, International Coöperation to Prevent War

Significance.—The most outstanding question of foreign policy in 1925 has been the proposed entry of the United States into the World Court. The movement has been transformed from the increasing support of a measure; it has become an adoption of A Cause; and this although the party in power under its leader, President Coolidge, has supported the Cause. The churches, the women's groups, and the universities have emphasized its specific and limited function in the cause of Peace.

Most of the woman saints have been reformers and statesmen. A high ideal and a definite program to realize it have been the two sides of their saintly shields. From Jael and Esther of the Old Testament to Joan of Arc and Catherine of Siena, they have risen from prayer and meditation to affect the conduct of Public Affairs.

Educational Process.—What part have the women of this country played for Peace in 1925? Soon after 1920 two women, both statesmen in a real sense, Mrs. Carrie Chapman Catt and Maud Wood Park, determined that women must do their duty as citizens in behalf of a sane foreign policy for Peace. That an active constructive Foreign Policy was a new necessity for this country, and that women everywhere must learn to be intelligent about foreign affairs. The state of affairs in 1925 is in part the result of a three-year educational process carried on by the League of Women Voters, the Young Women's Christian Associations, the American Association of University Women, the Federation of Women's Clubs and other associations.

Organization.—In January, 1925, the climax was reached and the nine largest national women's organizations met in Washington under Mrs. Catt's leadership and discussed the Causes and Cures of War with informed speakers for a week. This meeting registered the great progress already made in popular understanding; and it went on record for the World Court and the elimination of the causes of war.

In all parts of the country the women of the United States have united with their churches for Peace. They have joined with their universities, they have joined with public schools, they have lunched, tea'd, dined and radio'd for it. They have held talkers' schools and round tables everywhere—and all for Peace and the World Court.

Arousing Influence.—"How far is 1925 really different in this respect from any other year, have not women always loved Peace, and haven't they always talked about it?" The great game of 1925 is to illustrate the big truth that movements which coincide with strong human currents of belief and with normal action do succeed and not because they are opposed and indifferent to the advance of mankind.

Work for babies will always grow because almost all women will learn and make sacrifices for the sake of helpless children. Women do love Peace and they can learn to talk about it effectively.

Adult Education. — In recent months there have been new interests in the direction of concentration in the movement for adult education in international affairs, in organized efforts to get knowledge of affairs and spread it, and in the acceptance of the fact that machinery for Peace must be built by governments. As Elihu Root has said many times, "Peace can only come through the democratic control of International Affairs," and women have learned this lesson.

World Court.—To this end American women have accepted as one first measure the World Court, and have worked for it as citizens should strive for political ends—openly through accepted channels. Early 1926 will doubtless give many American women a deeper confidence in representative government by the passage of the measure permitting the United States to become a member of the Permanent Court of International Justice.

"If the world is to go forward along the line of regional pacts for Disarmament and Security, how about a Locarno Pact for the Pacific as a next step forward?" asks Mrs. Catt in November, 1925.

This year women have instituted new anniversaries—August 26, the fifth anniversary of suffrage, where old suffragists throughout the country spoke and wrote for the World Court and Peace.

LITERARY ACHIEVEMENTS OF AMERICAN WOMEN

By May Lamberton Becker

Editor, Readers Guide, Saturday Review of Literature

Prizes. — If we are to measure achievement by reward, American women writers have a good record for 1925. The Pulitzer Prize for fiction was won by Edna Ferber's *So Big*, the Harper Prize by Anne Parrish's *The Perennial Bachelor;* Martha Ostenso's first novel, *Wild Geese*, won $13,500 offered by a combination of publishing and cinema interests and Fannie Hurst's *Mannequin* carried off *Liberty's* $50,000 for a novel to serve as serial and as scenario. Women won three out of four of the first prizes offered by *Harper's Magazine* in its series of short story competitions: Alice Brown for "The Girl in the Tree," Fleta Campbell Springer for "Legend," Ada Jack Carver for "Redbone." Two of the second prizes in these competitions were won by women, Lisa Ysaye Tarleau and Edwina Stanton Babcock, and two third prizes, by Margaret Culkin Banning and Phoebe H. Gilkyson. In the annual O. Henry Short Story Competition Inez Haynes Irwin's "The Spring Flight" took first prize; and the third was won by Frances Newman (who has this year produced a scholarly work on the development of the short story) for "Rachel and Her Children"; while of the fifteen stories selected, for special merit, to appear in the volume resulting from this competition, six were by women. Poetry awards, or at least a part of them, are separately noted, and in these as well as in the many smaller competitions women's names appear often enough upon the lists of awards.

Novels. — Of the novels so decorated, *So Big* is less important as a work of art than as a sign of the times: its tremendous and prolonged popularity is another evidence of the number of Americans who at the height of a period of prosperity have become dissatisfied with their own standards of success. The distinction of *The Perennial Bachelor*, however, is less in theme than in technique: a family history stretching over sixty years, in which four women immolate themselves to rear one futile man, might easily have been not only gloomy but heavy; but Mrs. Parrish deftly permits the reader to discover that this man is not so much a creation of God as a masterpiece of four women, and that to justify its existence a masterpiece need not satisfy the public or the critics but only the artist; hence there is no overwhelming tragedy of frustration. It is quite likely that this novel will be one of the few of the year that will be here in ten years' time. So will *The Mother's Recompense*, if only because all that Edith Wharton writes must be taken into account by future appraisers of her part in our literature. This novel invests a situation more popular with French writers than with American readers with a pathetic dignity that sets it over her average of production. Two novelists have this year more than maintained their averages: Ellen Glasgow in *Barren Ground,* the story of a woman's lifelong struggle toward reconciliation with life, reaches the highest point in what has been for the most part a steadily mounting development; Willa Cather, in *The Professor's House,* has given us what may well be the outstanding novel of the year in the United States. It is now comfortingly clear that Miss Cather has cut loose from the pressure of the public, even of the unusually intelligent public which has from the first been hers, and is writing altogether from an inner compulsion, concerned only that her form of expression shall be appropriate.

Family chronicles and problems of society affecting family life continue to interest the greater number of women writers of fiction. Inez Haynes Irwin, in *Gertrude Haviland's Divorce,* gives sound, sane and sympathetic treatment to a subject usually clogged with sentimentality. To illustrate the range of novels of this general nature a list might well include: Kathleen Norris, *Little Ships;* Ruth Suckow, *The Odyssey of a Nice Girl;* Dorothy Speare, *The Girl who Dared;* Edith O'Shaughnessy, "Married Life" (a group of novelettes); Nalbro Bartley, *Bread and Jam;* Margaret Wilson, *The Kenworthys* (by the winner of last year's Pulitzer Prize); Helen Hull, *The Surry Family;* Janet Fairbanks, *The Smiths;* Marjorie Barkley McClure, *The Bush That Burned;* Isabella Holt, *The Low Road;* Fannie Kilbourne, *Mrs. William Horton Speaking.* In this field several newcomers have distinguished themselves, especially Rose Franken with *Pattern,* Helen Woodbury with *The Misty Flats* (both of these are studies of a relationship lately much under fire, that of mother and daughter) and Mathilde Eiker, whose extraordinary study of three women in *Mrs. Mason's Daughters* is as representative in its own way of an American social problem as Brieux's *Three Daughters of M. Dupont* or Chehov's *Three Sisters*, dealing with corresponding situations in France and Russia. *Prairie Fires*, by Lorna Doone Beers, outgrows the frame of a family novel, involves the fortunes of farming in the Northwest, and stands out as one of the most promising first novels in years.

Historical Fiction. — This list is headed by Honoré Willsie Morrow's *Romance of the Winning of Oregon*, told with the ingratiating honesty of the new type of historian, with Mary Johnston's *The Slave Ship*, of novels of this class. We have had besides, Bernie Babcock's addition to Lincoln apocrypha, *Booth and the Spirit of Lincoln;* Julia Flisch's *Old Hurricane;* Alice P. Smith's *Kindred*, and other romances concerned with past time. Such for that matter is one of the most distinctive of our novels, Elinor Wylie's *The Venetian Glass Nephew*, but this delicate fantastic escapes altogether from time and categories. Comparatively few women are writing successful detective stories, but the most popular one this year by man or woman was undoubtedly *The Red Lamp*, by Mary Roberts Rinehart, which twines two mysteries, crime and ghosts. Women continue to produce cowboy fiction, of which the entertaining tales of B. M. Bower (*Meadowlark* is the latest) are easily first.

Literary Biography and Autobiography.—The outstanding achievement in literary biography for America this year is Amy Lowell's *John Keats*, and her loss is the greatest loss to American literary criticism. Late in the season came two unusually important works, not only as literary biography but for the student of woman's part in our literary life; *The Diary and Letters of Josephine Preston Peabody*, edited by Christine H. Baker; and *Kate Douglas Wiggin as Her Sister Knew Her*, by Nora Archibald Smith. Earlier appeared *The Life and Letters of Mary Putnam Jacobi*, edited by Ruth Putnam; Ida Tarbell's *Life of Judge Gary*, and Clara Barrus's Boswellian record of *The Life of John Burroughs*. Mary N. Stanard not only edited unpublished letters of Edgar Allan Poe but published a biographical study of him as *The Dreamer*, and Corra Harris set down, in *As a Woman Thinks*, the conclusions reached by an author whose life has called for, and produced, a red-blooded philosophy. Women figure in all sorts of life-studies: Janet Scudder's *Modelling My Life*, is the autobiography of a sculptor; many an American actress appears in Mary C. Crawford's *Romance of the American Theatre*, and Mary A. Best presents Quaker biographies in *Rebel Saints*. There is a new, re-written version of Mary Austin's *The Man Jesus*, now called *A Small Town Man*. Mary Lawton preserves Katy Leary's memories of a happy American home in *A Lifetime with Mark Twain*, which though not the counterblast to Van Wyck Brooks for which it may have been intended, is for all that an invaluable addition to Twainiana. In *Catherine the Great*, Katherine Anthony exercises a technique exhibited in her earlier life of Margaret Fuller, upon a subject that gives it plenty of exercise.

Literary Criticism.—Some of the works of literary criticism are noteworthy, especially the arrangement of material and running commentary with which Frances Newman presents a robust subject in *The Short Story's Mutations*, and the contribution to our source material of social and literary history made by Jeannette R. Tandy in *Crackerbox Philosophers*. This list might well include Elizabeth H. Haight's *Horace and His Art of Enjoyment;* Ruth Phelp's *Earlier and Later Forms of Petrarchs Canzoniere*, and Edith Wharton's *Writing of Fiction*. While Dorothy Scarborough's *On the Trail of Negro Folk Songs*, is an important contribution to a subject just now being widely discussed. *Everyman's Genius*, by Mary Austin, is valuable not only for its ideas but for its careful documentation; this is true also of an uncommonly valuable contribution to phonetics, *Euphon-English*, by Margaret De Witt.

Travel books have quite lately become a favorite form of literary expression for women; women have written plenty of them all along; but a comparison of Blair Niles *Casual Wanderings in Ecuador* and *Colombia, Land of Miracles* with one of the bygone volumes of ladies' letters home will show what the change has been. American women now write from and about all corners of the map, as indicated this year by Grace Thompson Seton, *Yes, Lady Saheb*, for India; Elizabeth Crump Enders, *Temple Bells and Silver Sails*, for China; Elizabeth, *Touring Through France;* and Katherine Fullerton Gerould, *The Aristocratic West.*

L'Heure Joyeuse.—An American woman, Caroline Griffiths (Mrs. John Griffiths) has been this year signally honored not only by the French Government but by learned societies in France and England, for her unique work in connection with the establishment and maintenance of the first children's libraries in Europe conducted on the plan of the model American children's library. The value of *L'Heure Joyeuse*—the appropriate name of these libraries in France and Belgium—can scarcely be overestimated in its relation not only to literature and education, but to the building up of future and lasting international understanding. Accepted at first by the French as a gesture of friendship, it is being retained by them as a necessity, and its founder distinguished with many honors.

Poetry.—America is this year the poorer for two poets. It scarce seems possible, to anyone who came into personal relation with the rich and vibrant life of Amy Lowell, that her new book, *What's O'Clock?* should bear the word posthumous; she lived so intensely that it seems incredible that she should be dead. Edith Thomas, recluse and mystic, to whom life tasted always of immortality, had for years sung out of solitude, and much of her later verse is still in manuscript: Jessie Rittenhouse (Mrs. Clinton Scollard) is at work upon a collection of her poems published and unpublished. Martha G. Dickinson Bianchi, whose *Life and Letters of Emily Dickinson* is one of the most important of the biographies of our poets, has this year published her own volume, *Wandering Eros;* other versifiers are Aline Kilmer, *The Poor King's Daughter;* Grace Hazard Conkling, *Ship's Log;* Margaret Widdemer, *Ballads and Lyrics;* Sister Mary Angelita, *Sunshine and Candlelight.* It should be noted that a searching and spiritual study of the mediæval poem "Pearl" has come from another nun, Sister M. Madeleva, who earlier in the season published a genuine contribution to understanding of the "Canterbury Tales" in her *Chaucer's Nuns.* The *Collected Poems of H. D.* might be claimed for this list, for though the author, Mrs. Richard Aldington, is a British subject, Hilda Dolittle was born in America. Of comparative newcomers Leonora Speyer, whose second volume *Fiddler's Farewell* appeared this year, and Babette Deutsch, with *Honey out of the Rock,* are especially important to be kept in mind.

The sensation of the season in the popular sense has been made by the appearance of *Lava Lane*, by Nathalia Crane, who though twelve years old must be regarded, whether in ideas or their expression, as a woman and not as a child. Constance Lindsay Skinner has done remarkable work in presenting Aztec poetry; Muna Lee made notable translations from the modern Spanish verse of South America (the June number of *Poetry* was given up to these). Marguerite Wilkinson has a book about poets and their methods, *The Way of the Makers*, and Jeannette Marks, poet and dramatist, has made, in *Genius and Disaster*, a startling study of writers, including poets, under the influence of alcohol or drugs. The award of the *Pictorial Review's* $5,000 prize for the "most original and meritorious work done by a woman" to Mrs. Edward Macdowell could be entered as news of poetry-production, for the Peterboro Colony has made it possible for not a few poets to work unmolested.

Poetry Prizes.—Besides the long list of poetry prizes won by women, Martha Ostenso won the before-mentioned Curtis-Brown Prize of $13,500 at almost the same time as the appearance of her volume of verse, and in addition the *Dial's*

$2,000 award for "notable service to American letters" was won for 1924 by Marianne Moore, a poet. Olive Tilford Dargan won the Ward-Belmont prize in Tennessee; Louise Nicholls the *Lyric* prize; Alice Hunt Bartlett, American editor of the *English Review*, has been awarded a gold medal by the English Poetry Society for her services in promoting international relations in verse. Karle Wilson Baker took the prize of the South Carolina Poetry Society, Grace Crowell that of the Poetry Society of Texas, Agnes Kendrick Gray has the Mary Austin prize, Margaret Widdemer the *English Review* prize, Leonora Speyer the Chicago prize offered by *Poetry*. These are all important competitions open to men and women. The oldest and most important magazine of verse in America continues to be edited by its founder, Harriet Monroe, whose new volume, *The Difference*, may be out by the time this is in press. One of the most distinguished of the newer poetry magazines, *Palms*, is published by Idella Purnell at Jalisco, Mexico, and Louise Nicholl is largely responsible for the high quality of *The Measure*.

DIVISION XXIV
SOCIAL PROBLEMS

FAMILY LIFE

By John M. Gillette
Professor at the University of North Dakota

Any discussion of the family for the year 1925 is bound to differ somewhat in its nature from accounts of fields of physical science or mechanics. The family is not under control as is auto manufacture or laboratory experiments. We have to wait for things to happen to the family. There are so many families that on the average we do not know what happens to them for a good while after the event. Our records are fragmentary, incomplete, and far behind a given day, month or even year. We shall speak of the family, therefore, as it seems today, as it emerges out of the recent past.

Changes in Family Type.—Our United States family appears to be of the type that prevails in occidental countries. It is monogamic in form with an apparent tendency toward term marriage and what is coming to be called the companionate. This would indicate it is in transition. We are not obliged to think that it is moving over to some other form than monogamy, such as polygamy or polyandry—but clearly within the monogamic world considerable changes are going forward. Like other institutions the family has always been in transition. We are tempted to think that the changes occurring in it are now greater or more rapid than the average. If so, we must recall that our age is one characterized by the most varied and tremendous changes in scientific, mechanical, industrial and communication fields, and that these changes in turn set in operation other shifts and changes in all areas of human society. Thus we may well allow that the family of today is being jostled by and submitted to more disturbing currents and influences than in time past.

Influences on the Family.—Of the more important of the many influences that beat upon the family institution the following are worthy of enumeration. The results of scientific discovery and technical inventions work themselves out upon the family in many ways. They take things and processes out of the home, put others into the home; they make demands on purse and attention, and may put a strain on family ties; they tend to move people out of their home life and to substitute other satisfactions for those of the old type of home. Rising standards of living apply strains and shocks to the family ties. The opportunities of employment for women outside the home may postpone marriage, or prevent it, or cause seeming neglect of children by mothers who are employed. The Woman's Movement in its many forms is changing woman's thought about family and home matters. Some women plan to subordinate males to females, others to eliminate the males entirely, others to make females equal in all matters to males. Not only is the relation of women to men to be changed, but, in the minds of some woman leaders, the disposal and care of the offspring is to be altered—perhaps nearby institutions are to care for children. The revolution in industrial lines has taken out of the home many of its economic processes. As a consequence women of the middle class who can hire household help have abundance of leisure time, which is likely to be spent outside the home and often in empty activities. The widening knowledge of birth control has affected the size of the family and resulted in a parenthood by choice. Outside agencies are bidding for the children's time and interests—such as the public schools with their many attractions and demands, playgrounds, recreation centers and the movies. Lengthening the period of formal education may not greatly affect the masses, but it postpones marriage for a considerable number. The homes of a great majority of people have been urbanized, which means that they are chiefly eating and lodging places, outside agencies being depended upon to satisfy the larger parts of the interests and attractions.

Effect on Divorce.—These and other social influences are leaving their effects upon the family of the United States, as the following facts indicate. The ratio of divorce to marriage shows a great social change. In 1889 there was only 1 marriage in every 19 that ended in divorce. In 1895 the proportion ran to 1 in about 15; in 1900, to 1 in about 12; in 1916, to 1 in about 9; and in 1922, to 1 in 7. At the average annual rate of increase between 1905 and 1922, in 1925 1 out of every 6.85 marriages would presumably end in divorce. In some counties of the nation there are more divorces granted than marriages performed. Nevertheless, the marriage rate is increasing, according to the census figures; nor is marriage being postponed on the part of the masses.

Effect on Size of Family.—The size of family is exhibiting the effects of social conditions. In 1850 there were 5.6 members per family in the nation; in 1920 there were 4.3. Much of this change is doubtless due to urban influences; yet Ross and Baber show that the average farm family has fallen from 5.9 to 4.2 children per family during a generation.

For urban populations, the physical home appears to be undergoing a change. The home of several rooms is being displaced by one much shrunken—often to one large room equipped with convertible or disappearing furnishings and a kitchenette or its equivalent. It is alleged that the wide use of the automobile is largely responsible for this change. Meanwhile the percentage of homes rented grows apace and of those owned declines.

Hopeful Signs.—Notwithstanding, the home and family is not without redeeming and hopeful features. Thus Ogden, Ellwood and others have shown that among single, widowed and divorced persons the rates of mortality, crime, insanity and pauperism are decidedly higher than among those married. It is amply demonstrated also that juvenile delinquency is largely due to conditions of broken homes. Growing numbers of parents cease to think of their offspring as economic assets and appreciate them as developing personalities. Among rural inhabitants the home is the chief social institution for providing comforts and satisfactions; and for multitudes of urban inhabitants it remains the center and support of life's activities. The automobile is making its contribution in keeping the family united for outings and vacations; and the radiophone likewise unites the family to hear programs. Multitudes of agencies are on foot to rehabilitate broken down families, to provide foster homes for homeless and neglected children, to heal the breaches between husband and wife, to stimulate beautification and sanitation of homesteads. Churches and other organizations are devoting attention to reforming the family by improving conditions at marriage and to reduce the divorce rate. There is much agitation for amending the Federal Constitution so as to provide uniform divorce laws. Since only about 25 per cent. of all divorced persons live outside the state of their marriage, it would seem that the preponderating portion of such interstate immigrants move for business and other reasons and not to secure a divorce. Far greater results could be secured by properly regulating marriage in the individual states and by training youth to understand the responsibilities of wedded life.

ORGANIZED SOCIAL WORK

By HORNELL HART

ASSOCIATE PROFESSOR OF SOCIAL ECONOMY, BRYN MAWR COLLEGE

Reaction.—Critics of our civilization are prone to refer to the present as a "machine age," and to slur the achievements of recent decades as being confined to "material progress." That the spectacularly rapid developments of our epoch are not confined to mechanical inventions is strikingly evidenced by consideration of progress in the field of social work. Age-old humanitarian impulses have in our generation seized upon the two great tools of modern times—science and organization—and are paralleling in the field of social work the achievements which these same tools have made possible in intellectual and industrial fields. An outstanding feature of the year 1925 in social work is the accumulation of instances indicating that the rapidity of this development toward organized and scientific philanthrophy is creating a pronounced reaction in certain quarters—a reaction which, while not appearing likely to destroy the progress of the past half-century, offers a challenge and an indictment which social workers and the socially-minded public must meet if the trends toward fundamental solutions of social problems are to be carried forward in the future as in the past.

Development of National Organizations.—Over fifty years ago the National Conference of Corrections and Charities (since renamed the National Conference of Social Work) was founded by a group of leaders among the boards in charge of state prisons, reformatories, asylums and kindred institutions. They were soon joined by the Charity Organization Society group of men and women who were trying to systematize the chaotic endeavors of amateur relief societies to meet the problems of families in their homes. In the nineties the settlement workers, keen in their sympathy for underprivileged peoples in whose neighborhoods they had made their homes, came into the Conference with the plea—"Not charity, but justice." And then, in the early years of the century, came the rise of preventive social movements, national in scope, and the mounting interest in industrial conditions as causes of misery and unrest; until in 1912 through the Conference a program of minimum labor standards was formulated which was almost bodily lifted into the platform of the Roosevelt Progressives.

Meetings and Programs of 1925.—The development in social work which now holds the center of the stage is the growth of federated relationships among social agencies, a process commonly but inadequately described as the Community Chest Movement. As Paul U. Kellogg writes of the 1925 National Conference of Social Work:

> The Denver conference may thus be said to mark the tidal reach of this new organizing force in local social work—its coming to power as the charity organization and settlement groups forged to the front in their day. And here an interesting thing is to be set down. The conference division through which this group especially functioned—that of organization of social forces—was given up not to a rarification of problems of charitable finance but to the engineering of city-wide services. The shift was unmistakable; history was repeating itself. Sooner or later the basic human claims underlying all social work assert themselves, as against all questions of institutions, procedures, administrations, budgets. Under the chairmanship of Sherman C. Kingsley, whose executive leadership in Cleveland and Philadelphia has been one of the genuine assets of this newer movement, there were taken up in turn in a series of remarkable papers the range and contents of city-wide service in the fields of health, of family welfare, of recreation, of dependent children. Moreover, in the councils of the American Association of Community Organization, which met as a kindred group, the function of this national body was reconsidered and the part it can play forecast in rehabilitating local chests and federations, in bringing leading laymen in the movement in contact with men of their stamp in backward communities; and also in broadening their concern from money-raising to organized service.

Some other phases of this Conference are summarized by Mr. Kellogg as follows:

> The reëmergence of the county as an administrative unit and psychiatry as a new tool in institutional work were taken up by the division on public officials and administration. The division on delinquents and correction confirmed the mounting interest on all sides in behavior problems as did the kindred meeting of the National Probation Association. The mental hygiene division was itself rich in fresh drafts of experience; its contribution to case work in a score of fields has come to stay. There are psychologists so bold as to predict that their group will supplant the sociologists in moulding the social practice of the future, but they could not have said so with such confidence had they attended the spirited section meetings on neighborhood and community life or the related kindred group meeting. . . . The Denver meetings may be said to have staged the "come back" both of child labor and of immigration as active public questions.
>
> In the industrial field, whether the matter under discussion was that of regularizing employment, of labor's part in management, of coöperative banks and production, of labor education or of industrial hazards, there was promise that future conferences will witness the resurgence of interest in economic conditions and relations and the division committed to them.
>
> The section on children—one of the oldest of the conference—was as always one of the best attended and richest in discussion, and the same can be said of that on the family, which trenched on two of the most active issues in public concern before the conference—the migratory families and auto camps which have thrust new and baffling problems on every community in the West; and those questions of marital relations which the section discussed under the heading of the family and the law. In a sense the election of Miss Vaile was a spirited rejoinder by fellow social workers the country over to her dislodgement by the Klan governor of Colorado; but in a deeper sense it was a recognition of the fundamental contribution of the family case worker to the totality of social work. . . .
>
> In the Health Section twenty-seven papers were presented either by physicians or upon topics requiring a knowledge of health supervision on the part of the authors, a good evidence of the inseparable relation between socially-minded doctors of medicine and the other brotherhoods and sisterhoods of social work. . . .
>
> The newest comer of the conference sections was that on professional standards and education. The discussions at the five section meetings underscored the rise of morale. Analogies with other professions were resorted to much less frequently than in the past; social work, for better or worse, is standing on its own legs.

Relative to this last item the following quotation from a paper by Frances H. McLean at the 1925 meeting of the American Association for Organizing Family Social Work is pertinent:

> The year 1924-1925 in the field work of the Association shows increasing emphasis placed upon systematic, careful, philosophical training, on the need for skilled case-work service

and more of it, and increasing attention to projects which involve not only these intensive activities, but fundamental extensions of our thinking as well.

A new Training School for Jewish Social Workers has been inaugurated this year in New York City and a training school for institutional workers has opened at Dobbs Ferry.

Community Chest.—The war stimulated the development of social work not only through its Red Cross Home Service, its War Comp Community Service, and its mental testing, but also through its highly organized Liberty Loan drives. But the "drive" method of financing, as applied to federations of the social agencies in a town or city, is perhaps the most outstanding heritage of war expansion in social work.

Joint financing began in Denver in the late 80's, but very few cities adopted it until the World War. This year at least 227 cities in the United States and Canada have united their charities in federations or chests for purposes of mutual support, but chiefly to carry on the raising of money jointly from the public. The American Association for Community Organization reports that the total amounts raised by listed community chests during the past three years, ending May 31 of each year, have been as follows:

1923	$40,000,000
1924	49,000,000
1925	56,000,000

Of the urban population—in cities of over 30,000—66 per cent. is now living in community-chest cities. Of the total population, 22 per cent. may be so classified.

While Phidalelphia is the largest city yet federated in its financing of social agencies, Cleveland and Detroit have established financial federation on a firm basis of successful experience and Boston has this year been "on the brink" of adopting the plan.

Pittsburgh has this year inaugurated the chest method. New York City during the past year has advanced toward closer coöperation among its 2,000 social agencies by the organization of a new Welfare Council. A striking new development in centralized financing has been the organization of its own chest by the fur industry in New York City. This means federated giving, as contrasted with federated money-raising. The Fur Industry Chest in 1925 raised $480,000 from 1,876 individuals and firms in the trade. It is asserted that the contributions represent an increase of 30 per cent. over former contributions from the same givers.

New National Organizations.—Further evidences of the development of the movement toward more highly organized machinery for carrying on social work are the announcement by the American Association for Community Organization (which has been the national clearing-house for local community chests since 1919) that on January 1, 1926, it will progress from volunteer officers to the employment of its own full-time executive staff. Similarly, the National Council of Social Work, representing some fourteen national social agencies, has developed to the point of employing a full-time secretary. The year has shown, then, a continuation of the tendency toward more and more organization in social work—toward confidential exchanges through which social agencies share each other's knowledge of the individual family problems with which they deal, toward councils where community policies are formulated, toward joint financial campaigns and joint budgeting of needs, and toward the creation, on city-wide and then on national, bases of organizations to promote the aims involved in social work.

Methods. — Increasingly scientific methods as well as increased organization have characterized the trend. Social workers build their programs upon the study of cases—the method of dealing directly with facts and conditions as well as with theories. The case method has gained both in the technique through which individual problems are understood and treated, and in the variety of fields in which it is applied. To the methods of careful investigation and patient endeavor to understand the true needs and resources of the clients dealt with, the new psychology has added the technique of the psychiatric social worker, who is learning to readjust not merely the environment but also the mental processes of the maladjusted person. An increasing literature of case studies is growing up, based upon rigidly scientific and yet deeply sympathetic study of social misfits. The Commonwealth Fund has been financing experiments in the development and promotion of such methods in social work.

Case Work.—This covers a great variety of specialties. Visiting nursing, which began in a settlement in New York thirty-two years ago, has spread until school nurses, insurance nurses, public health and industrial nurses add their efforts to a movement which has been a powerful factor in the revolutionary reductions in death rates achieved during the past quarter century. Case work done in connection with courts and correctional institutions by probation and parole officers has grown to an exceeding bulk, including not only juvenile courts, in which it originated, but also domestic relations courts where family quarrels are unraveled and strained ties knit up again, and even extending into courts for adult offenders against the law. Relief of poverty is being developed through the swiftly growing case work of mother's allowance departments. In industry, personnel administration has adopted case-work methods in many establishments in dealing with absences, sicknesses and other problems affecting the welfare and efficiency of the employees. The public schools have been discovering the need for case workers, called visiting teachers, to go into the homes of children whose school work is being damaged by problems outside the school. Even college deans are beginning to recognize that their problems require the technique used by social workers.

Relief vs. Organization.—This growth of scientific and organized methods of dealing with social problems has been so swift that it invites a sharp reaction. Past years had already shown evidences of misunderstanding, but in 1925 the dissatisfaction of certain groups with the methods of social workers has taken new and more sensational forms. An instance has been the action of Leopold Schepp, the "cocoanut king," in asking through the press for advice on how to use his millions, stipulating that he was not interested in existing institutions or in organized charity. A kindred instance is the following, taken from an article in the *Literary Digest* for August 29, 1925:

> William J. Conners of Buffalo and West Palm Beach, Florida, recently announced the creation of a fund of $1,000,000 which is to relieve distress immediately, without red tape, without respect to creeds. . . . Mr. Conners, who climbed from stevedore to wealth and power in the business and political life of his State, . . . expects to increase the fund to $5,000,000. The foundation will be exclusively for the people of Buffalo. . . . It will be independent of any other charitable activity; it will relieve first and investigate afterwards. . . . "It was undoubtedly the observation—if not the actual experience—of Mr. Conners that is often hedged about with so much administrative machinery that it loses much of its sweetness by the time it reaches its beneficiary," remarks the Schenectady *Union Star*, adding: "Elaborate office staffs and card indexes are all very well in their way, but the quality of mercy is not strained through a card index."

Restoration Policy.—This urgency toward immediate and untrammeled relief as the chief object of "charity" presents a fundamental conflict with the ideals of modern social work. The Charity Organization Society movement was based originally upon the idea of service rather than relief—"Not alms, but a friend." The permanent restoration of the dependent family to self-support and self-respect rather than a mere temporary relief of emergency needs has been the goal set. This ideal has been reiterated during 1925. Instance the following excerpts from the *Survey*, for October 15, 1925:

> Maurice J. Karpf, for six years superintendent of the Jewish Social Service Bureau of Chicago, has created a new kind of report which he calls a Social Audit. . . . Probably the most courageous feature of this fearless "audit" is its attitude toward relief. We have grown complaisant these last few years on this subject. Everything has conspired to make us so: the socialization of medicine, mother's pensions, industrial compensation, the rising standard of living, the short-sighted nature of much social work publicity have all driven us to the granting of larger and still larger amounts of relief. Against this tendency, Mr. Karpf's "audit" is a ringing protest. He sees more clearly, probably, than a

> worker among non-Jewish clients could discover, the demoralizing effect of much of our relief giving; a great deal of his work during the six years he was with the Chicago society was to discover and use methods for correcting this evil. . . .
>
> His primary defense, however, against relief giving is case work; case work done by trained, competent and experienced case workers, carrying not too great a load.

That greater experience in social work means decreasing relief is indicated by an investigation in Minneapolis:

> In the Minneapolis Family Welfare Association, it was possible to make a study covering two years' experience, during which time all district secretaries were replaced. This study showed that in the six months following the change of a district secretary the district spent on the average eight thousand dollars more in relief than normally, or than it did either before the change or after the district secretary got hold of her job.

To this attitude of social workers toward relief, growing though it does out of prolonged, expert and sympaethetic dealing with problems of poverty, the trained social worker not only has not converted the general public, but has in many cases failed to convince even the boards of directors supposedly closely in touch with the work. This divergence of opinion is certain to provoke continual friction and misunderstanding until fuller comprehension is achieved.

Access Methods.—This need for fuller comprehension social workers have by no means ignored. Outstanding features of the 1925 National Conference of Social Work were a competition to select the playlet most effective as a means of getting across to the public social problems and social ideals, and the presentation of a play on the subject of unemployment. The All-Philadelphia Conference of Social Work organized this year a highly effective conference and exhibit on "Every Child in Philadelphia." Skillful publicity has been a prominent subject under discussion by social workers in 1925.

Charitable Finance.—Not only the question of relief but also the new methods of financing social work seem to be provoking a growing restlessness in certain sections of the public. Joint financial drives were intended to eliminate the annoyance of repeated solicitation but the success of the method—raising as it has unprecedented sums of money for charitable purposes—has stimulated the initiation of drives by great varieties of organizations not included in the federations or "chests." Many social agencies note an increasing difficulty in raising funds, or complain that financial resources are not expanding rapidly enough to meet the growing demands which have been stimulated, at least in part, by the new methods of financial campaigning. A number of campaigns have failed to raise the amount called for in the budgets of the member agencies, placing them in serious dilemmas. In Philadelphia, the deficiency in the amount raised in the fall of 1924 resulted in the adoption of the policy of refusing to accept more cases than the incomplete budget justified. The 1925 campaign, however, was the most successful in the history of joint financing in Philadelphia. In the five years of welfare drives in Philadelphia the amount raised has increased from less than two million to over three million dollars.

In Columbus, Ohio, the Family Agency wished in 1925 to undertake only as many cases as it could deal with adequately with its limited funds, while the officers of the Community Fund wished to have some attempt made at service in behalf of each applicant. As a result of this conflict (together with other complicating factors) the Family Agency has been excluded from the fund for 1926.

National vs. Local Agencies.—Certain national agencies who have to raise funds in cities where there are chests find that the refusal of the chests to include them acts almost as a blacklisting of these agencies with many givers. Other social workers note that the chest method increases the domination of social work by business men. On the other hand many social workers feel that the business man has raised the level of efficiency in the federated agencies and that joint financing has undoubtedly resulted in more adequate budgets and staffs.

Another type of reaction against the social work movement is illustrated by the statement made by Bishop Charles Fiske in the American *Mercury* for August, 1925, to the effect that one of the worst pests in America to-day is the welfare movement, and that "no one could possibly estimate the harm that has been done to all movements for social betterment by the paid uplifter."

Federal Action.—A reverse felt keenly by workers for better labor legislation has been the Supreme Court decision in October, invalidating the Arizona Minimum Wage Law and with it all such laws in the United States except that of Massachusetts.

The at least temporary failure of the child labor amendment (dealt with more fully in another section of the *Year Book*) reflects among other things distrust of organized regulation of and interference in family life.

Attitude toward Criminals.—Perhaps more emphatic than any other symptom of reaction against the methods in vogue in organized social work has been the recent agitation relative to crime. The Loeb-Leopold trial in Chicago served to focus attention in a spectacular way upon the psychiatric approach to criminal problems. The popular impulse toward severe punishment of a cold-blooded and horrible crime was thwarted, according to the views of the ordinary man, by the interference of certain paid experts. The fear that social work will interfere with the severity of punishment is reflected in such newspaper statements as that of the Detroit *Free Press*, suggesting that legislation against armed bandits "should be backed up in a manner making it impossible for a sentimentally inclined parole official to pardon one of this class and turn him loose again to prey on society, as is now too often the case." Social work concentrates its efforts upon the salvage of the individual, believing that through that method society also will be best protected; public sentiment has shown signs of demanding the protection of life and property regardless of the welfare of the offender. The Chicago and Cook County Bankers' Association offered last summer a reward of $2,500 to any police or bank officer who killed a thug while engaged in bank robbery; the reward offered for information leading to mere arrest and conviction was only $1,000.

Emphasis of Social Work.—Social work is changing its fundamental emphasis. It is coming to recognize as its goal the release of human purposes, so that those who are thwarted through conflict within themselves and with the purposes of their fellows may be given the opportunity to function joyfully in ways that can be built into a rising structure of social purpose. Thus conceived, social work has a far wider task added to the mere granting of food to the hungry and clothing and coal to the shivering. It has the problem of the development of human relationships toward fuller life for all. The acceptance of this ideal does not involve a decrease in the determination to relieve the world's suffering; rather it means an intense resolve that sympathy shall become increasingly effective, and that the social aspirations of humanity shall not defeat themselves through short sightedness, but shall issue in genuine and increasing achievements of welfare for mankind. It was in the truest spirit of modern social work that William J. Norton, in his presidential address to the 1925 conference, upheld love as the mainspring of social work, as the "thin film of protection between the wheels of life which lubricates them and keeps the whole machine from being burned out in the merciless friction of living," as the force which "lifts man from the plane of the beasts and stretches his stature upward until he can see and hear God."

RECREATION

By L. E. Bowman
Secretary, National Community Center Association

Interest.—Recreation is taking on more extensive forms, public and private. Evidences have multiplied in recent months that a good time is an accepted part of life, not only to be taken as it comes along and enjoyed, but to be planned for by the individual, his community, the state and even the nation. More consciously than ever before municipalities are providing recreation areas before increasing population fills up the vacant spaces. New York State has created a council on parks that is seeking the acquisition of available land to be held if necessary a generation before a growing population needs it and to be utilized only for the relaxation and recreation of its present and future citizens. The National Recreation Congress heard demands more specific and insistent than ever before that government—national, state, municipal—provide for and on behalf of the whole people, and at public expense, "that which so vitally affects the quality of its citizenship." Perhaps the developments of automobiles and other modern devices are taking people out of their homes more and sociability is taking on a more extensive character; probably too leisure time is increasing and giving many of all classes more opportunity to be sociable.

Facilities.—The recreation facilities are made available for the year round more than in previous years, according to the figures published by the Playground and Recreation Association of America. The recognition of the place of outdoor play has been very strikingly shown in the plans of many of the real estate projects that have come into being in answer to the housing shortage. Playgrounds, playfields, even community houses have been made integral parts of large developments undertaken each by one man or firm. The national organization has printed ten fundamentals for real estate, emphasizing the opportunities in the hands of home planners, the economy in the long run, and the credit for provision of play spaces that will be given to those who plot communities, fundamentals that have been agreed to and signed by many real estate dealers.

State and city recognition of recreation responsibility has lately taken a definite form in the "Home Rule" bills enabling cities to secure year round recreation systems under existing municipal bodies or under a Recreation Commission or Board which might be created and to appropriate funds for the work. Twenty-one states now have these Home Rule laws, twelve of them with referendum features. Some of the laws include a provision allowing any two cities, towns, counties, school districts jointly to establish and conduct such a system. A tax levy may be made by the commission or other authority.

Practicality.—Together with the more universal acceptance of play as a normal function to be provided for, there seems to be more of a business-like attitude toward it, and a common-sense rather than propagandist flavor to the statements of its organizers. The Woman's Division of the National Amateur Athletic Federation of America has been very active in the coördination and stimulation of athletics for girls and women. Its platform contains significant planks dealing with: the need of physical activities for all members of groups rather than for a chosen few, protection of athletics from exploitation for the enjoyment of the spectator, stressing of enjoyment of the sport rather than winning, discouragement of sensational publicity; women directors of athletics, medical examinations and the conservation of health through physical activities, appropriate and sensible costumes, discouragement of gate receipts and travel. The Women's Division is helping greatly to set standards for girls' activities, especially through its handbook with rules, and separate pamphlets on some activities. It is becoming more comprehensive in scope and groups affected.

Ages and Sexes.—The tendency of the last few years has developed to make the playground and all recreation activities serviceable to as many as possible, eventually all classes, all age groups, both sexes. Diversification is seen in the establishment of more and different winter sports, swimming, wading, recreation centers, community drama, music forums, motion pictures, etc. Kenneth Clark of the National Bureau for the Advancement of Music made a study of municipal music, finding in 762 cities an expenditure of $1,254,481.17. In addition public school music totaled in costs $3,621,008.82. The Playground and Recreation Association is helping to stimulate the movement through a committee on Municipal Music. Music memory contests and national music weeks have grown in number, as have singing groups, community bands, harmonica bands, ukelele classes, children's symphonies and barber shop quartettes. Interest in community drama has taken shape in numbers of drama groups and drama tournaments, institutes for the training of volunteer workers and in dramatic activities on the playground, in the centers, etc.

This tendency to an all-round program is seen in the increase in golf provided under municipal auspices, showers for children put up in city streets, training in home play, provision of facilities especially adapted to foreign speaking groups and of special games in public parks, cricket, bowling on the green and racing of exquisite boat models under rigid and complex rules. There are several studies in progress.

Moral Effect.—Long ago it was said and it seems to be said more often, in more quarters, and more fervently every year, that recreation prevents delinquency. Instances are cited although conclusive studies are not available, probably because of the many factors involved and the difficulty of tracing effect of recreation on a mass of growing and usually migrating children. However, every new book of the many new ones on psychology, education or child training brings added general confidence in the educational values in play and the great potentialities as yet undeveloped in this direction.

The workers in play activities have taken the matter seriously and are tackling the psychologist and sociologist on their own grounds. They are demanding scientific analysis of the character-developing virtues of play and games. The terms are vague and the technique of study as yet embryonic but the process of analysis is wholesome and the contact of practical worker and academic mind is beneficial to both. The aims professed are the finest, such as "to insure the full all-round development of the individual, and the complete manifestation of his capacity, to develop attitudes—which will enrich personality and which will be most worthwhile in carrying over values as the girl becomes the woman." A representative committee is at work formulating a study of the effect of play activities in the development of character traits aided by advice from certain university men.

A Civic Service.—The advocacy of playgrounds may have begun largely as an effort at betterment and reform by the few of and for the many, but the recreation movement today including playgrounds is becoming a general tendency, a mass effort, civic in its characteristics rather than charitable. "Get acquainted with the politicians and handle small details with them" is repeated this year to the Recreation Congress. Get all recreation under public control and support it with taxes, is the slogan of the protagonists of this work. True commissions are urged by private citizens to stimulate and watch public officials, but the aim is clearly public administration. Combined public and private administration shows up in the yearly statistics. Playgrounds are urged and are being put more and more under school supervision. Committees of recreation workers more generally than in other social enterprises include both public and private officials.

Labor has officially endorsed recreation efforts. President Green has vigorously advocated playgrounds and other general forms of play, and the American Federation has urged the matter to locals. Thirty state federations have passed resolutions in favor of more recreation facilities, especially those municipally furnished.

A further development somewhat in this general direction is the National Contest for Playground Beautification which is being conducted by the Playground and Recreation Association, awards given by the Harmon Foundation to encourage the beautification of America's playgrounds. A total of $4,650 in prizes is offered for competing playgrounds making greatest progress from October 6, 1925, to November 1, 1926. The avowed purpose is to make the playground a civic asset, desired by the taxpayer and citizen. Plantings of trees and shrubbery to form a buffer for sight and to some extent hearing are suggested.

RESULTS OF QUESTIONNAIRE ANSWERED BY 1,113 CITIES
(Playground, Vol. 19, No. 1, April, 1925.)

Total number of play areas under paid leadership (711 cities)	8,115
Areas open the year round (530 cities)	1,701
“ “ summer months (633 cities)	3,626
Total number of play areas open in 1924 for the first time (231 cities)	635
Total number outdoor playgrounds (652 cities)	5,006
Open the year round (145 cities)	862
Total average daily attendance of participants (471 cities)	881,500
Total acreage of outdoor playgrounds (364 cities)	9,580
Total valuation of outdoor playgrounds (179 cities)	$43,099,459.97
Total number of outdoor playgrounds open in 1924 for first time (168 cities)	444
Total number of playgrounds for colored children (58 cities)	133
Indoor Recreation Centers	
Total number indoor recreation centers (193 cities)	1,763
Open the year round (76 cities)	489
Total average daily attendance (81 cities)	66,110
Total valuation indoor recreation centers (26 cities)	$13,458,389.00
Total number indoor recreation centers open for first time in 1924 (34 cities)	155
Total number indoor recreation centers for colored citizens (37 cities)	46
Community Houses	
Total number community houses (123 cities)	288
Open the year round (100 cities)	240
Total valuation community houses (25 cities)	$ 2,659,544.00
Total average daily attendance (44 cities)	23,850
Total number of community houses open for the first time in 1924 (7 cities)	7
Total number of bathing beaches (154 cities)	293
Bathing beaches open for first time in 1924 (5 cities)	7
Total average daily attendance (54 cities)	57,551
Total number of golf courses (95 cities)	131
Total average daily attendance (22 cities)	8,713
Total acreage golf courses (31 cities)	4,752
Total valuation of property (17 cities)	$ 3,128,576.00
Courses open in 1924 for the first time (5 cities)	6
Total number summer camps maintained in connection with recreation program (83 cities)	123
Total average daily attendance (28 cities)	5,034
Total acreage camp property (22 cities)	1,121.5
Total property valuation summer camps (11 cities)	$ 87,800.00
Athletic fields (439 cities)	1,330

Quoit Courts (247 cities)	2,327
Swimming Pools (272 cities)	626
Places for Water Sports (215 cities)	458
Skating Places (266 cities)	1,076
Ball Fields (460 cities)	2,522
Total number of employed workers (711 cities)	15,871
Men workers	6,577
Women workers	9,294
Total number of workers employed the year round (300 cities)	2,783
Cities reporting work supported by municipal funds	302
Cities reporting work supported by private funds	195
“ “ “ “ “ municipal and private funds	199
Total expenditure for recreation purposes (662 cities)	$20,052,558.02
Total amount issued in bonds for recreation purposes (28 cities)	$11,801,817.54

CHILD WELFARE

By C. C. Carstens

Executive Director, Child Welfare League of America

Child Labor Amendment.—During the past year the most outstanding event was the submission by Congress of the Child Labor Amendment to the States that were holding legislative sessions. It came before forty-three legislatures and was ratified by both houses in only four States. It may be ratified by other States at later sessions of the same legislatures, for the amendment is still legally pending.

Although no progress in combatting child labor was made through federal legislation during the year there has been marked legislative improvement in various States, the outstanding achievements coming in Michigan where the school superintendent was given power to institute a system of child accounting and can require that the child's records be sent after children who have left a particular school district, in Wisconsin where the Industrial Commission has been granted power to pass regulations regarding agricultural child labor in certain industries, and in Pennsylvania where new regulations on industrial home work have been passed, and school attendance has become compulsory for children from eight to sixteen during the entire school year.

Child Type Census.—The Bureau of the Census has announced some advance statistics. During the first six months of 1923 a census of various types of children was taken. During that period in the census of delinquents it was found that 945 juveniles under eighteen were admitted to prisons and reformatories and 2,445 to jails and workhouses. The previous census to gain similar facts in 1910 showed that about 10,000 were correspondingly in the last group. In 1910 2,345 children under sixteen were admitted to penal institutions, while in the first six months of 1923 only 283 were admitted to them.

In the census of dependent children, on February 1, 1923, 192,156 children were reported in various institutions for children, and 68,779 under care of the child-placing agencies. In addition 130,000 children were reported as being aided through Mothers' Assistance Funds in their own homes.

Legislation.—Out of the mass of legislation passed by the many legislatures in session the following are the most essential forward steps:

In a number of States non-support, desertion and abandonment statutes have been strengthened. In Massachusetts no order for support has previously been binding for more than two years. This year the period has been lengthened to six years and no civil proceeding is now a bar to prosecution under penal law. In New Mexico, North Carolina and South Carolina there has also been improvement in some statutes. In Indiana, Iowa, Ohio and Oklahoma laws for probation have been improved.

In Pennsylvania an adoption law which seems a very good piece of legislation has been passed, as well as a measure for licensing and regulating infant boarding homes caring for children under the age of three.

In Michigan a five-day period has been established between the application for and the issuance of a marriage license.

Louisiana, Rhode Island, Vermont, and Hawaii have been added to the States working in coöperation with the United States Children's Bureau under the provisions of the Maternity and Infancy Act, making a total of forty-three States and Hawaii.

In New York a series of laws was passed very much improving the legal status of children born out of wedlock.

Minnesota passed a law providing for placement by the State board of children hard to adjust in free homes; a Children's Bureau was authorized by the Legislature of Iowa, a Department of Public Welfare was organized out of the union of two state agencies in California. The Bureau of Child and Animal Protection of Montana was modified so as to eliminate the work for animals, and the President signed a law passed by the Federal Congress providing for the use of probation in the various Federal Courts.

Child Welfare Organizations.—The Chief of the United States Children's Bureau attended the session of the Child Welfare Committee of the League of Nations, in Geneva, May 20-27, 1925. This Committee was organized as one of two committees by the League's Advisory Commission for the Protection and Welfare of Children.

Additional interest has been aroused in both the physical care and social development of crippled children. Fraternal orders and civic and luncheon clubs have been particularly active in their behalf, and an International Society for Crippled Children, with headquarters at Elyria, Ohio, has been organized.

Early in the year the 25th Anniversary of the first juvenile court and the 15th Anniversary of the first psychiatric clinic were celebrated in Chicago. The psychiatric clinic movement has continued to hold the interest of many communities. Child guidance or psychiatric clinics have been opened in Philadelphia and the University of Virginia through coöperation with The Commonwealth Fund of New York, and other clinics have gotten under way in Evanston, Illinois, in the State Industrial Schools of Massachusetts, and in a number of other places.

The Commonwealth Fund's project of extension of visiting teaching has also led to ten of the cities where the demonstration period was completed to continue the visiting teacher as a regular feature of the public school system.

A Conference was called in New York during the year for the purpose of strengthening the Mothers' Assistance Laws in the various States, under the auspices of the Child Welfare Committee of America, attended by delegates from at least forty-four States.

A National Training School for Institution Executives and Workers opened October 1st, under the auspices of the Children's Village at Dobbs Ferry, New York.

Birth Registration.—The Birth Registration Area was increased by the addition of West Virginia, which now includes thirty-three States, and the Death Registration Area includes forty-one States.

Trends in Child Welfare.—Several trends in child welfare, whose beginnings date further back, have during the past year become more pronounced. Among these the following are noted:

A broader application of social case work principles to the care of individual children, whether in family homes or in institutions; the wider use of individual family boarding homes for child-care and the correspondingly smaller use of free home placement of children; the reëxamination of the functions of institutional care and family home care for both dependents and delinquents; the use of both methods by certain agencies after having made careful diagnosis of the needs of each child; the emphasis on saving the child's own home, through reconstructive action or preventive measures rather than rushing into court or social action for the removal of the child.

CHILD LABOR

By Owen R. Lovejoy

General Secretary, National Child Labor Committee

Proposed Constitutional Amendment.—In 1924 Congress adopted what is known as the Federal Child Labor Amendment, which reads as follows:

> "Section 1.—The Congress shall have power to limit, regulate, and prohibit the labor of persons under eighteen years of age.
>
> "Section 2.—The power of the several States is unimpaired by this article except that the operation of State laws shall be

suspended to the extent necessary to give effect to legislation enacted by the Congress."

In 1925 this amendment was before the legislatures of forty-three states for such action as they chose to take. It was ratified by three (previously also by Arkansas) and rejected by twenty-two, which was more than a fourth of the states, and therefore ensured rejection. In the other states the matter did not come finally to either ratification or rejection by the action of both houses.

The General Counsel of the National Association of Manufacturers appeared to lead the opposition but the Editor of the *Southern Textile Bulletin* developed the most effective propaganda against it, successfully organizing the farmers in opposition through the so-called Farmers' States Rights League.

State Legislation.—Child labor was discussed more in 1925 than in any previous year. From schools to churches, from afternoon semi-social parties to meetings of political organizations, speakers pro and con appeared everywhere. School debates on the amendment are still going on. The people have had an opportunity to learn about the subject as never before.

The widespread discussion undoubtedly had an effect in arousing the people to a sense of their responsibility on the one hand and in giving them a more or less clear understanding of what is held to be reasonable protection on the other. For the year 1925 was marked by legislative improvement in a number of states.

California placed the burden of proof upon the employer and improved her law as to children working in theatrical and vaudeville entertainments.

Connecticut abolished certain exemptions to her night work prohibition in bowling alleys, and established a 58-hour week for women and minors under sixteen.

District of Columbia made school attendance compulsory between seven and sixteen during the entire session except those over fourteen who had completed the eighth grade.

Georgia established a fourteen-year age minimum for enumerated employments; a sixteen-year age minimum for certain enumerated dangerous occupations; prohibited night work from 7 P. M. to 6 A. M. for children under sixteen; provided for a work permit based upon proof of age, ability of the child to read and write; required a physician's certificate of physical fitness for that particular employment.

In Michigan the State Superintendent of Public Instruction was given power to institute a system of child accounting, and as a result of this records of children are transmitted from one school district to another.

New Mexico established a fourteen-year age minimum during school hours by abolishing a necessity exemption; established a sixteen-year age minimum in certain specific occupations dangerous or hazardous; established an eighteen-year age minimum in mines and quarries; established an eight-hour day, and a forty-four-hour week for all children under sixteen.

New York established a forty-four-hour week for children under sixteen employed in certain occupations.

In Pennsylvania, by ruling of the Industrial Commission, the requirements for license for the employment of children were extended and certain forms of work prohibited except in the immediate families, and appointment of some person by the employer as his representative in the home.

Tennessee made a physician's certificate of physical fitness for the particular employment a prerequisite for a work permit.

Texas established an eight-hour day and prohibited night work for children under fifteen.

In Wisconsin the Industrial Commission was given power to pass regulations with respect to the employment of children under sixteen at certain agricultural work, as cherry orchards, beet cultivation, etc.

Wyoming strengthened materially her law in regard to certain prohibited employments for persons under sixteen.

SOCIAL HYGIENE

By Ray H. Everett

Editor, "Journal of Social Hygiene"

Signification.—Social hygiene, as it has become accepted generally in the United States, has both a broader and narrower significance than is given it in England and on the Continent. In those countries it is thought of as dealing with a broad group of maladies to combat which many research and propaganda agencies have been formed. In recent practice, however, the trend is toward a broader interpretation of the subject and in England, especially, social hygiene is being employed to denote the special sex problems of health and morals connected with life in civilized communities. The recent change in name of the British National Council for Combating Venereal Diseases to the British Social Hygiene Council is indicative of an expanded program. In the United States its connotations are limited to problems dealing with and growing out of sex relations, which, medically at least, confine its activities to the discovery and development of measures to control and prevent the venereal diseases.

Though thus limited in a medical sense, however, the field of social hygiene in this country has come to embrace the study of a far broader series of acts and conditions which bear directly on the welfare of the family and the home. Such problems, for instance, as marraige, divorce, illegitimacy, prostitution, and other forms of sex delinquency—these and their like which tend to sustain or destroy our basic social relationships —now are considered definite and proper questions to be investigated and, where possible, adjusted by the agencies working in this field. Many of these problems would exist if there were no so-called venereal diseases, although oftentimes they are aggravated and made more difficult of settlement through the presence of these diseases. Further than this, social hygiene in its positive aspects aims to reach, not only those who might otherwise become immoral, but every individual. Sex education should be a natural, logical part of the life-training program of all.

Early Agitation.—The earlier stages of the movement in this country were marked by the forming of several organizations, all having the general purpose of bettering social conditions, but each seeing its own program as of greatest importance. Perhaps the best grouping of the three major bodies of opinion would be: first, those whose primary object was to treat and cure the venereal diseases by medical measures; second, those who were affronted by the commercial prostitution which prevailed so widely and waged their fight by means of legal measures; and third, that group who were bent mainly on securing wholesome, accurate, character-training education for all—particularly for youth. In the early years of this century various members of these groups commenced to think more and more in terms of a broader program which would include the best features of all of their individualistic plans and would unite the forces working toward a common end. This realization of the desirability of and necessity for a farseeing, comprehensive program to meet the many and various problems which are inherent in this field resulted in the merger of the several most important voluntary agencies in 1914 and the formation of the American Social Hygiene Association.

Venereal.—At this time the most urgent phase of the movement was the combating of the venereal diseases. Clinics were few and far between; many physicians refused to treat persons infected with these diseases; quacks flourished and the public was inclined to be either apathetic or antagonistic. Most of these handicaps were due to a failure to distinguish between the public health aspect of syphilis and gonorrhea and the moral issues involved. To many people the sufferer from a venereal disease was merely a victim of his own folly, whereas public support and appropriations could be enlisted more readily for fighting other plagues. This being so, it was natural for national, state, and local health officials to hew to the line of least resistance and make their major efforts in fields where they were certain of sympathy from their taxpaying constituents. Less than ten years ago it was the exception rather than the rule to find a hospital where venereal-disease patients might find refuge.

Administration.—To note all the progress in the social hygiene field would require volumes, but an enumeration of some of the outstanding facts is most encouraging and promising for the future. In the Field of Public Health, Medical and Nursing Measures, bureaus or divisions of venereal diseases have by now been established in practically every state and large city in the United States. In no other public health field has there been a more general and rapid official recognition of the needs for special work. Laboratory facilities have been provided by most of the states and cities to meet the need of free diagnosis and as aids to clinical supervision of cases. Treatment and drugs have, likewise, been made available without cost to those in very limited circumstances. The increase of from fewer than 200 clinics in 1916 to more than 800 at present is a notable one. Research has been promoted to determine new and better ways of diagnosing, treating, and following up cases, and nursing and social service activities are being extended to the venereal diseases and increasingly recognized as essential parts of the program for their control.

There still are a number of persons in this country who believe that segregation and medical regulation of prostitution is the best method for dealing with it, but so strong a preponderance of public opinion now demands the suppression of prostitution that the latter may be considered the settled policy in the United States.

Legal Measures.—Vice surveys and studies of laws and law enforcement have been made in the typical population centers of the United States, some of which are being continuously followed up to check the dependability of the findings. Repression of commercialized prostitution has become the course pursued in the United States, and the "red-light" districts together with municipal toleration of open vice have virtually disappeared. Laws and ordinances have been greatly strengthened both as to dealing with prostitution and in the control of the venereal diseases. An important beginning has been made in devising better administrative machinery for law enforcement. A glimpse can be gained of some of the legislation which has occurred during the last year and which is related directly or indirectly to social hygiene when one reads that Regulation 19 of the Ohio Sanitary Code has been amended so as to insure the reporting of cases of venereal disease; that the passage of the Copeland-Graham Probation Bill in the United States permits the Federal Courts to place young offenders on probation; that the Injunction and Abatement Bill was passed in West Virginia and Rhode Island; and that Louisiana has joined the ranks of states requiring a physical examination as a prerequisite to the issuance of a marriage license. Public recognition of the necessity for legal measures in this field is general but, for all this, volunteer agencies cannot yet reduce their efforts in the United States to the extent possible in the medical field because our public authorities are not equipped with the funds or personnel to carry out a program comparable to the official medical measures now in operation.

Educational and Character Training Measures.—The opposition to sex education often comes from those who do not understand either its content or its technic, but the sex taboo is going and those most responsible for the education and training of the young—educators, teachers, parents, social and religious workers—are promoting studies of sex social problems and facing the responsibility of aiding the youth of the country toward a sounder sex adjustment in life.

Present activities in this aspect of social hygiene include the integration of proper sex education into the routine courses of higher institutions of learning. The some caution, sureness of ground, and demonstration of practicability before advancing any proposals, which have characterized the development of the whole social hygiene program, mark the efforts in education. Those educational leaders primarily responsible for it agree absolutely that the home is the best starting place for sex instruction and that parents, if equipped, are the ideal persons to give it. They agree further, however, that sex education, as a normal phase of character education as a whole, is a progressive process which should cover the period from earliest childhood through maturity and beyond. In this process all agencies which have to do with the education and training of the individual must play their parts. Schools, colleges, and churches must build upon and supplement the work of parents. As for instruction in matters of sex as a grade-school activity —here, as in the higher institutions, sex instruction must come as a normal feature of broader subjects. Until parents and educators have been brought to the point of action along sound lines in this field, volunteer agencies must bear the burden of progress as they have in the preceding phases of the movement.

Protective and Recreational Measures.—With the study of commercialized prostitution and the successful fight against it there has come a realization that the protection of young people in danger of becoming sex delinquents is a vital link in the armament against both prostitution and the venereal diseases. The safeguarding of play and amusement facilities whether they be commercial or free; the work which policewomen and visiting teachers carry on: in fact, the protective supervision of the community's youth in general for the prevention of sex delinquency should be woven into the social hygiene pattern.

The protection of youth should receive even greater attention than the rehabilitation of sex offenders because a stronger effort directed toward protection would ensure fewer offenders. Most young people are readily influenced by their environment, either toward clean, wholesome living or the reverse according as that environment is good or bad. Past emphases in this field have been on detention and rescue homes, reformatories, and other rehabilitative facilities rather than on measures which would tend to make such facilities less essential. The trend of protective measures today, however, is toward cleaning up, and keeping clean, the environment rather than neglecting it; toward the appropriation of more public funds for the prevention of delinquency rather than the use of these funds for salvaging projects. Toward this end the states are promoting legislation for physical education; policewoman courses have been established; prizes are being offered for the greatest progress in playground beautification; salacious literature is being attacked from every quarter; "keeping-fit" essay contests are being held in the schools; social organizations are providing better and safer homes for working girls in crowded cities; and every effort is being expended to protect youth.

Social Hygiene an International Problem. — Taken geographically, throughout the Western Hemisphere there is a considerable measure of agreement on many features of the social hygiene movement. With a few minor exceptions the program of Canada is similar to that of the United States, and many features of this broad scheme have been adopted in Central and South America. The All-America Conference on Venereal Diseases and Social Hygiene held in Washington, D. C., December, 1920, under the auspices of the American Red Cross, the United States Public Health Service, and the American Social Hygiene Association brought together leaders from all the Americas and resulted in the locating and development of many common ground basic principles for work. During the past year, as in other years, exchange visits have been made between countries for the purpose of studying social conditions, and the international aspects of the problem of venereal disease control and the so-called "traffic" in women and children are being given more attention than ever before.

SELECTED BOOKS ON SOCIAL HYGIENE

ADDAMS, Jane.—*A New Conscience and an Ancient Evil.* N. Y., Macmillan, 1912. From long experience and from authoritative data Miss Addams discusses, sanely and frankly, questions which eternally confront civilized society. Her suggestions for solutions are eminently just, pertinent, and sympathetic.

BIGELOW, Maurice Alpheus.—*Sex Education.* N. Y., Macmillan, 1919. An admirably sound and rational book, dealing with the meaning, scope, problems, and methods of sex-education; value and dangers of sex books; special instruction for preadolescents; bibliography.

CADY, Bertha Chapman, and CADY, Vernon Mosher.—*The Way Life Begins.* N. Y., American Social Hygiene Association, 1917. A simple, scientifically accurate book for parents and teachers on the beginnings of plant, animal, and human life. Illustrated with colored plates.

CHAPMAN, Mrs. Woodallen.—*How Shall I Tell My Child?* N. Y., Revell, 1912. Shows the mother how to answer in the simplest manner the early questions of her children concerning the origin of life.

FLEXNER, Abraham,—*Prostitution in Europe.* N. Y., The Century Company, 1914. A refutation of segregation and reglementation.

GALLICHAN, Walter M.—*A Textbook of Sex Education for Parents and Teachers.* Boston, Small, 1921. Especially valuable because it includes chapters on instruction for adolescent boys and for adolescent girls.

GALLOWAY, Thomas Walton.—*The Biology of Sex. For Parents and Teachers.* Boston, Heath, 1913.

Deals especially with the methods and spirit of sex instruction and its biological, social, and moral foundations.

Galloway, Thomas Walton.—*The Father and His Boy.* N. Y., Association Press, 1921. Sex training made wholesome and effective through democratic comradeship between father and son.

Galloway, Thomas Walton.—*Love and Marriage. Normal Sex Relations.* N. Y., Funk & Wagnalls, 1924. The various elements, biological, social and sexual, which make up a successful and happy married life.

Galloway, Thomas Walton.—*Sex and Social Health.* N. Y., American Social Hygiene Association, 1924. Analyzes modern sex-problems and presents the best contributions of thought and scientific study devoted to them. Thorough and well-balanced, rich in practical methods of procedure—especially valuable to teachers and leaders of young people.

Gray, Arthur Herbert.—*Men, Women, and God. A Discussion of Sex from the Christian Point of View.* N. Y., Doran, 1923. Association Press, 1923. An inspirational discussion of the problems of sex from the churchman's point of view, but based, in general, on sound scientific principles.

Gruenberg, Benjamin Charles.—*Parents and Sex Education. Children Under School Age.* N. Y., Am. Soc. Hygiene Assn., 1923. An explanation of the nature and psychology of the child for parents of children under school age, with a statement of the principles and methods of educating the child in the matters of sex.

Gruenberg, Benjamin Charles.—*High Schools and Sex Education.* Prepared under the direction of the Surgeon-General, U. S. Public Health Service, in collaboration with the U. S. Bureau of Education. Wash., U. S. A., 1922. Manual of suggestions on education, related to sex, based on work done by high school teachers. Contains practical suggestions from many sources. Bibliography.

Gulick, Luther Halsey.—*The Dynamic of Manhood.* N. Y., Association Press, 1917. Supplements Exner's *Rational Sex Life for Men* on the philosophical side.

Gulick, Luther Halsey.—*A Philosophy of Play.* N. Y., Association Press, 1920. The ripened conclusions of the greatest American exponent and innovator of recreation, written from twenty years' first hand experience.

Hood, Mary G.—*For Girls and the Mothers of Girls.* Indianapolis, Bobbs-Merrill, 1914. Presents the facts of life for girls and their mothers in a simple, dignified way. Recommended for public and school libraries.

March, Norah Helena.—*Sex Knowledge.* N. Y., Dutton, 1922. Information for the general reader on questions of sex.

March, Norah Helena.—*Towards Racial Health. A Handbook on the Training of Boys and Girls. For Parents, Teachers, and Social Workers.* N. Y., Dutton, 1918. Covers the field of practical sex education, laying equal emphasis on the biological approach and on ethical considerations.

Miller, Hugh Crichton.—*The New Psychology and the Teacher.* N. Y., Seltzer, 1922. Valuable for its presentation of the child's emotional development during the early years, and suggestions for wise guidance.

Moore, Harry H.—*Keeping in Condition. A Handbook on Training for Older Boys.* N. Y., Macmillan, 1919. Sex hygiene is made an integral part of a general program of physical training for boys in their teens. Recommended for public and school libraries.

Royden, A. Maude.—*Sex and Common Sense.* N. Y., Putnam, 1922. Discusses, with an inoffensive frankness, the part sex must play in the life of the well-balanced individual. Essentially spiritual, yet not apologetic for the physical.

Snow, William Freeman.—*Venereal Diseases. Their Medical, Nursing, and Community Aspects.* N. Y., Funk & Wagnalls, 1924. A non-technical discussion of cause, spread, treatment, cure and prevention of each of these diseases, and social hygiene questions which relate to them.

STOKES, John H.—*The Third Great Plague. A Discussion of Syphilis for Everyday People.* Phila., W. B. Saunders Co., 1917. Not a work on diagnosis and treatment, but an accurate presentation of the social, medical, and ethical aspects of syphilis, seeking prevention through education.

MENTAL HYGIENE

BY GEORGE K. PRATT

ASSISTANT MEDICAL DIRECTOR, NATIONAL COMMITTEE FOR MENTAL HYGIENE

PROGRAM

Rest and Control.—Following the close of the war, leaders of the official mental hygiene movement took steps to capitalize the psychiatric gains of that period and incorporate them into an expanded program. This program on a nation-wide scale was designed closely to parallel accepted public health practices in other fields of preventive medicine. To achieve this it first became necessary to crystallize into definite policies certain activities heretofore regarded merely as significant trends. Also it became necessary to shift the emphasis of certain tendencies to other aspects of the mental hygiene problem. These matters more or less satisfactorily disposed of, mental hygiene entered upon a renaissance that already has placed it well to the fore of the country's great public health movements. Outstanding among its policies and assuming definite shape is the larger dedication of a major part of its activities to the prevention of mental diseases and to the preservation of mental health.

Present Concepts of Mental Disease.—Gradually since 1919 has come a clarification of former medical concepts of mental diseases. The present tendency is to recognize the mentally sick person as a *whole* human being and not just an impersonal sort of "case," constructed of two distinct units;—a separable mind and a separable body. Modern medicine tends to disregard anatomical boundary lines and to insist that the sufferer from mental illness have study given as much to his personality, his frustrations, his prejudices and his desires as to his liver, his heart or his digestion.

Dr. C. Macfie Campbell, Professor of Psychiatry at Harvard Medical School and Director of the Boston Psychopathic Hospital, portrays the current psychiatric concept of mental disease as follows: "Mental hygiene is not concerned merely with those serious forms of mental disorder which require treatment in State hospitals; it is concerned with those other forms of mental disorders which do not necessarily mean the removal of the individual from his ordinary social environment. A disorder is a mental disorder if its roots are mental. A headache indicates a mental disorder if it comes because one is dodging something disagreeable. A pain in the back is a mental disorder if its persistence is due to discouragement and a feeling of uncertainty and a desire to have a sick benefit, rather than to put one's back into one's work."

FEEBLEMINDEDNESS

New Concepts.—Until a few years ago the consensus of medical and lay opinions held that the feebleminded were few in numbers; that they were all potential menaces to the community; that they invariably owed their mental defect to heredity; and that the only satisfactory solution to the problem they created lay in their lifelong institutional segregation. Among nearly all psychiatrists today feeblemindedness (a defect or arrest of intelligence as contrasted to the emotional impairment in "insanity") is recognized as a widely distributed condition. No state has as yet made an accurate enumeration of all the feebleminded within its borders. It is known, however, by repeated surveys that at least 2 per cent. of the public school population of any given community is below the average intellectual intelligence. Fernald estimated after careful comparisons, that in Massachusetts—a state of approximately three and a half million persons—there were at least 50,000 feebleminded. Similar percentages have been estimated for New York State.

ACQUIRED MENTAL WEAKNESS

Newer and recent discoveries in other branches of medicine have disclosed the percentage of accidental or acquired cases of feeblemindedness to be much larger than was once thought. Thus birth injury, due to unavoidable accident or to careless obstetrics, plays a not insignificant role in the causation of later intellectual arrest. So also does the onset of infectious disease during the early months of infancy. Scarlet fever, whooping cough, infantile paralysis, and perhaps most of all, now that it is being more readily recognized, "sleeping sickness" (encephalitis lethargica) may, and often do, result in feeblemindedness in children with no demonstrable ancestral taint. Fernald and others credit these "accidental" causes with producing 50 per cent. of all cases of mental deficiency.

Character.—It has also been amply demonstrated that not all, by any means, of the feebleminded are "bad" or community menaces. Fernald states that less than 10 per cent. of all mental defectives are inherently vicious and that the other 90 per cent. are not unduly troublesome. Experiments in special institutions demonstrated that with proper training, a majority of the feebleminded can be educated to the limit of their stunted intelligence and then taught a simple trade or occupation prior to being returned to their communities. There, under moderate supervision, they become loyal, hard-working and law-abiding citizens, capable of partial, if not complete self support. The inherently vicious 10 per cent., known as defective delinquents, will always require strict institutional care.

Sterilization. — Present psychiatric tendencies also reject surgical sterilization as a solution to any but a relatively few types of cases. This attitude is based on the knowledge that approximately only half of all cases are due to a defective germ plasm, and that existing information is not sufficient to enable anyone to detect in most instances which are inherited and which are acquired defects. Moreover it is believed that while sterilization may solve a fractional part of the problem (for those cases obviously due to defective heredity) it is likely to create serious new problems in rendering more easy the spread of venereal disease through increased prostitution.

JUVENILE DELINQUENCY

Concepts.—In this field, too, many new concepts are being accepted by a growing number of socially-minded courts and judges. These concepts revolve around a fundamental realization that children who commit anti-social acts are not necessarily led to do so by such abstract and conventional urges as original sin or sheer cussedness, but rather by some motive that to them appears necessary if the integrity of their personalities and their need for individual expression is to be preserved. As a result of this belief many juvenile courts since 1919 have availed themselves of the services of psychiatrists in endeavoring to uncover the basic reasons for the anti-social acts that commonly bring young culprits before them.

Examination of Prisoners.—From time to time in the past studies have been made of the mental condition of inmates of jails and prisons. The most thorough study of this kind made up to the present time was undertaken in 1922 by the National Committee for Mental Hygiene. The survey included individual psychiatric, physical and social examinations of 1,228 prisoners confined in thirty-four county jails and penitentiaries in New York State. The survey staff consisted of three units each in charge of a Director who was an experienced psychiatrist, assisted by a score of other psychiatrists, psychiatric social workers and psychologists.

A summarized report of their findings follows:

Sixty-six per cent. of the persons examined were recidivists, i.e., had been arrested previously, the arrests numbering from two to fifty.

Seventy-seven per cent. were psychopathological individuals of well recognized types.

Twenty-two and nine-tenths per cent. were found to be normal (i.e., free from recognized mental abnormalities.)

7.6 per cent. were definitely feebleminded.
5.4 per cent. were borderline feebleminded types.
7.2 per cent. were "dullards."
42.2 per cent. had psychopathic personalities.
1.5 per cent. were psychoneurotics.
0.9 per cent. were epileptics.
7.3 per cent. were "insane."
4.5 per cent had definite personality defects.

ESTABLISHMENT OF CLINICS

The Habit Clinic was created in Boston, in 1922, by Dr. Douglass A. Thom for children of pre-school age (i.e., from two to six years). At these clinics Dr. Thom assisted by a trained staff of psychiatrists, psychiatric social workers and psychologists examine certain children who are "problems" because of the manifestation of one or more habits that may be classified into three groups: (1) Those undesirable habits connected with the organic life of the child (but for which no physical pathology can be found) such as faulty, finnicky eating, faulty sleep broken by night terrors, bedwetting, elimination, sex habits, and others. (2) Habits associated with personality deviations such as excessive daydreaming, temper tantrums, fearfulness, belligerency, shyness, or with anti-social habits of lying, stealing, truancy, and the like. (3) A group of motor habits including peculiar mannerisms, tics, muscular jerkings, etc. It is among such displays, when habitual and excessive, that the genesis of much adult maladjustment, nervous disorder, or even frank mental disease has been found to come.

Child Guidance Clinics.—Another psychiatric agency assuming an important place in modern social work is the Child Guidance Clinic. Two of these are in operation at this writing: one in Cleveland and the other in Philadelphia. Each is engaged in a two-year demonstration of what a properly organized psychiatric clinic may be expected to contribute to the social work, the court practice and the educational facilities of a community. These clinics were made possible by a grant from the Commonwealth Fund administered through the technical staff and resources of the National Committee for Mental Hygiene. The first demonstration clinic was established in St. Louis in 1922. Since then demonstrations (usually for one year) have been conducted in Memphis, Minneapolis, St. Paul, Los Angeles, as well as in Cleveland and Philadelphia, where current demonstrations are being carried on on a two-year basis.

Child Guidance Clinics accept for diagnosis or treatment certain children up to sixteen years of age who are in need of psychiatric attention because of some personality deviation or some emotional maladjustment. The clinics coöperate intimately with courts, schools and social agencies from which many children are referred. It is also significant that in each city where a Child Guidance Clinic has been established a large number of parents bring their children for examination without first passing through one of the agencies mentioned above.

NEW TREATMENT FOR MENTAL DISEASE

Malarial Treatment for Paresis.—Two outstanding discoveries in the field of treating certain types of mental disease have been announced in recent years. Both of these affect one disease in particular, namely, general paresis. The so-called malarial treatment of paresis as elaborated by White of St. Elizabeth's Hospital in Washington, by Bunker and Kirby of Manhattan State Hospital, New York, by Solomon of Boston and other research workers, appears to consist essentially in the intravenous inoculation of the patient with a tertian-strain of malaria inducing the characteristic symptoms of this disease. These symptoms are critically observed and after reaching a certain degree of intensity (as denoted by clinical and blood study) are checked by the administration of quinine and sulphate in carefully calculated doses.

The beneficial results obtained by the malarial treatment of paresis are assumed to depend on the formation of non-specific immune bodies, the presence of which renders the host less habitable for the spirochætes. Various hypotheses are offered concerning the nature of the destructive effect this treatment exerts on the trypanosomes of syphilis. Sufficient time, however, has not yet elapsed to study the subsequent course of treated patients, and until this can be done the value of the malarial treatment of paresis cannot permanently be established.

Tryparsamide.—The second of the two therapeutic discoveries referred to is a chemical one. Late in 1919 a group of research workers consisting of Doctors Lorenz, Loevenhart and Hodges entered on a study of the treatment of syphilis of the central nervous system with a view to the development and use of drugs. As a result they worked out a form of therapy for early general paresis and other types of neurosyphilis that utilizes tryparsamide and mercuric salicylate. For purposes under discussion Lorenz uses tryparsamide in doses of three gm. dissolved in c.c. of sterile freshly distilled water, and injected intravenously at one week intervals for eight weeks. Three days before the tryparsamide, mercuric salicylate in one grain doses is administered intramuscularly. A total of nine such injections alternated with eight injections of tryparsamide comprise a course of treatment. From six to eight courses usually are given to secure clinical improvement.

Development of Psychiatric Social Work.—Psychiatric social work is the branch of social case work that deals with cases of social maladjustment in which a mental factor or a behavior problem is of primary importance. The wide range between the social problems arising in connection with acute mental disorders (so-called insanity, etc.) and those involved in milder personality maladjustments and faulty childhood habits have resulted since 1920 in considerable divergence in emphasis in various psychiatric social work positions.

Although five years ago the number of trained psychiatric social workers was almost negligible, at the present time there are about 350 psychiatric social workers, more than half of whom are thoroughly trained. The most important developments in the last five years have been the establishment on a permanent basis of the courses in psychiatric social work given at the New York School of Social Work, and the Smith College School for Social Work. Other schools have in the past few years inaugurated courses in mental hygiene, but have not undertaken to train students specifically for immediate work in the psychiatric social work field.

SOCIAL WORK IN THE CHURCHES

BY HERBERT N. SHENTON
PROFESSOR AT COLUMBIA UNIVERSITY

National Organizations. — Within recent years social work in the churches has been marked by a widening of the scope of the activities by national organizations, some outstanding coöperation between Catholic, Jewish and Protestant groups, the development of interdenominational work among Protestant bodies, the adoption of several new statements of social faith by Jewish and Protestant bodies, and by an increasing emphasis upon research as a basis for social action.

Within the Catholic church, the department of social action of the National Catholic Welfare Conference has made significant contributions by the holding of an annual Catholic Conference on Industrial Problems and by issuing statements to the press on public questions. In these statements there has been an opportunity at times to apply the comprehensive body of social teaching of the Catholic Church to present day issues. This department has headquarters at 1312 Massachusetts Avenue, N. W., Washington, D. C. The chairman is the Right Reverend P. J. Muldoon, Bishop of Rockford. The directors are Dr. John A. Ryan and Dr. John A. Lapp. The director of the Bureau of Rural Life is Dr. E. V. O'Hara, whose office is in Eugene, Oregon.

Catholic Conference on Industrial Problems.—The third annual meeting of the Catholic Conference on Industrial Problems was held in Chicago, June 24-25, 1925. The program consisted of presentations and discussions of the following topics: "The Labor Injunction," "The Present Position of Working Women," "Conciliation and Arbitration," "Insurance of Employees." The Catholic Conference on Industrial Problems was established in Chicago late in 1922. Since then, two meetings have been held, one in June, 1923, at Milwaukee, and the other in May, 1924, at Pittsburgh. These meetings have the purpose of discussing industrial questions in the light of Catholic social teaching. Though still in its infancy, the Industrial Conference gained the friendship and confidence of both employers and labor leaders. The fairness of the program, the way in which all sides of every question under discussion are given a hearing, and the lively and intelligent handling of the questions from the floor of the Conference have convinced everyone in attendance at the meetings held thus far that the Catholic Conference on Industrial Problems has carved a place for itself.

The Conference lays emphasis upon Pope Leo's Encyclical on the Condition of Labor. The members and the formal speakers so far have all been Catholics. Bound together by this tie, and a common acceptance of the teachings of Pope Leo's Encyclical, they have been able to go ahead to determine for themselves by open discussion what its instructions mean in American industry. There is no thought in the Conference of forcing any specific view upon any of the members or committing the Conference itself to any definite platform. The Conference is forbidden by a clause in its own Constitution from voting upon any question of industrial policy.

Department of Social Action.—During recent months typical releases of the Department of Social Action were summarized as follows in the *National Catholic Welfare Conference Bulletin:*

"The comparative productivity and costs in the building trades were investigated by the United States Bureau of Labor Statistics and a résumé of this investigation was published by the Social Action Department. The investigation revealed the fact that the widespread credence given to the statement that building labor is inefficient, as compared with former years, is entirely unfounded in fact.

"'Perverting the Sentiment of Patriotism' is the title of a Social Action Department news sheet. The news sheet warns against two societies, active at the present time, whose real aim, hidden under pseudo-patriotic and popular phraseology, is opposition to industrial reform. Their ostensibly patriotic purposes are revealed for what they are in their actual performances and in the personnel of their officers. According to the news sheet, 'every movement in which they take an active part, aims at the stabilization of economic abuses. The majority of their officers are, directly or indirectly, the beneficiaries of economic injustice.'

"The people of the United States are responsible for the less than living wages received by the maintenance of way employees on our railroads. The Social Action Department calls attention to a little pamphlet called 'Is It Just and Reasonable?' which contends that the annual wage of $880 paid maintenance of way employees is not a living wage, and that the Railroad Labor Board, the instrument of the people, in this field, is responsible and should remedy the condition."

Rural Life Bureau.—The Rural Life Bureau is of service to rural parishes and organizations which deal with rural problems. Its program as developed reveals a wide range of interests and the application of Catholic social teaching to a variety of rural problems. The Bureau is interested, for example, in promoting a Christian view of land tenure; the promotion of a wide diffusion of land ownership and of easy access to land by bona fide operators, the coöperative movement, with safeguards against becoming merely capitalistic; development of the electrification of the farm home, avoidance of unsuitable work for rural women and children, reinforcing the religious bond with the social bond, the integration of education and religion, employment of dramatics and chorals.

Central Conference of American Rabbis.—The Social Justice Commission of the Central Conference of American Rabbis presented in 1925 a "program of social justice" at the convention of the Union of Hebrew congregations and its affiliated organizations—the National Federation of Temple Brotherhoods. In presenting the program, the leader of the group, Rabbi Louis Woolsey, said that "the entire development of Judaism, from its earliest beginnings down to our very day, has been a clarion call to an entire humanity to follow justice through to every concrete application." The program as adopted was as follows:

1. More equitable distribution of the profits of industry.
2. Minimum wage which will insure for all workers a fair standard of living.
3. The legal enactment of an eight-hour day as a maximum for all industrial workers.
4. A compulsory one day of rest in seven for all workers.
5. Regulation of industrial conditions to give all workers a safe and sanitary working environment, with particular reference to the special needs of women.
6. Abolition of child labor and raising the standard of age wherever the legal age limit is lower than is consistent with moral and physical health.
7. Adequate workmen's compensation for industrial accidents and occupational diseases.
8. Legislative provision for universal workmen's health insurance and careful study of social insurance methods for meeting the contingencies of unemployment and old age.
9. An adequate permanent national system of public employment bureaus to make possible the proper distribution of the labor forces of America.
10. Recognition of the right of labor to organize and to bargain collectively.
11. The application of the principles of mediation, conciliation and arbitration to industrial disputes.
12. Proper housing for working people, secured through government regulation when necessary.
13. The preservation and integrity of the home by a system of mothers' pensions.
14. Constructive care of dependents, defectives and criminals, with the aim of restoring them to normal life wherever possible.
15. Freedom of speech.
16. Federal legislation against lynching.
17. Liberal immigration laws and Americanization provision.

Rabbi Horace J. Wolf of 117 Gibbs Street, Rochester, New York, is secretary of this commission.

National Council of Congregational Churches.—The National Council of Congregational churches, at its sessions in Washington in October, 1925, adopted a statement of social faith prepared by its Social Service Commission. This is a long document, and states what the teachings and ideals of Jesus mean if translated into certain human relations: for example, into industry and economic relationships, education, agriculture, racial and international relations. Some of the more significant declarations of this statement are as follows:

"That the church of Christ as an institution should not be used as an instrument or an agency in the support of war.

"A permanent association of the nations for world peace and goodwill, the outlawry of war, and the settling of all differences between nations by conference, arbitration, or by an international court.

"That the cost of market distribution from farmer to consumer shall be cut to the lowest possible terms, both farmers and consumers sharing in these economies.

"The elimination of racial discrimination, and substitution of brotherly treatment for all races in America."

The office of the Social Service Commission of the Congregational churches is 14 Beacon Street, Boston.

Statement on Twelve-Hour Day.—An outstanding instance of coöperation between social work departments of different faiths was furnished by the joint statement on the twelve-hour day in the steel industry, issued by the Social Action Department of the National Catholic Welfare Conference, the Social Justice Commission of the Central Conference of American Rabbis, and the Commission on the Church and Social Service of the Federal Council of Churches. The issuance of this statement, calling for the abolition of the twelve-hour day in the steel industry, was influential in securing the favorable action of the American Iron and Steel Institute.

Federal Council of Churches.—The Commission on the Church and Social Service of the Federal Council of Churches (105 East 22nd Street, New York City) serves to coördinate the work of the departments and commissions of most Protestant bodies in the field of social service. It conducts a service bureau to give assistance to local churches in studying their problems, in making surveys, etc.; it conducts community and industrial conferences which aim at the promotion of a better understanding between employer and employed; it has a committee on child welfare which coöperates with the Child Welfare League which has employed a secretary who gives his time to serving the churches; it has stimulated interest in work for delinquents and prisoners and has made a study of various aspects of church service to delinquents; it worked to secure the ratification of the Child Labor Amendment; and prepares annually a Labor Sunday Message for use in the churches.

National Denominational Organizations.—Among National Denominational organizations engaged in social service are the following:

Board of Temperance and Moral Welfare of the Disciples of Christ, Occidental Building, Indianapolis.

Commission on Social Service of the Congregational Churches, 14 Beacon Street, Boston.

Church League for Industrial Democracy (Episcopal), 6140 Cottage Grove Avenue, Chicago.

The Commission on Christian Social Service of the Protestant Episcopal Church, 281 Fourth Avenue, New York.

Methodist Federation of Social Service, 156 Fifth Avenue, New York City.

Department of City Work, Methodist Board of Home Missions, 15th and Arch Streets, Philadelphia.

Commission on Social Service and Rural Work of the Reformed Church in the United States, 14th and Race Streets, Philadelphia.

Social Service Commission of the Universalist Churches, 176 Newbury Street, Boston, Mass.

Department of Social Education, Baptist Publication Society, 1701 Chestnut Street, Philadelphia.

Various boards of home missions as well as various departments of the national Y. M. C. A. and Y. W. C. A. regard social service as a function of their work.

Institute of Social and Religious Research.—In social research the outstanding developments are the formation of an adequately financed Institute of Social and Religious Research and the expansion of the program of the Department of Research and Education of the Federal Council of Churches. The Institute of Social and Religious Research (370 7th Avenue, New York) was formed in January, 1921, for the purpose of conducting and disseminating results of scientific research and surveys in the socio-religious field. Many surveys have been made by the Institute but increasing stress is being laid upon research studies calculated to yield more exact and penetrating methods of analyzing social data and to show underlying factors and general trends. It is not a service agency though it counsels with organizations desirous of undertaking social studies and surveys.

While it is organically independent it frequently coöperates with educational, religious and governmental agencies. Several of its studies have extended into foreign countries. Monetary grants have been made to a few significant national and international agencies promotive of coöperation among religious and educational bodies, particularly in the mission field. Among the projects thus far undertaken are: the rural church in typical counties; church surveys of St.

Louis and Springfield, Mass.; the World Missionary Atlas; oriental race relations on the Pacific Coast; a basic inquiry into character education; theological education (whites and negroes); moral and religious factors in twenty-four colleges and universities; changes in habits and institutions in a small city since 1890; Christian literature in Moslem lands; a preliminary inquiry regarding social research in China; studies in Negro Contacts, and American agricultural villages.

Information Service.—The Department of Research and Education of the Federal Council of Churches (105 East 22nd Street, New York City), issues a weekly Information Service which consists of reviews of current material on race and international relations, urban industry and agriculture, and on the work of religious organizations doing social work. It is regarded by students in various fields as one of the most reliable sources of case material in social ethics. It is published on a subscription basis at $2.00 a year and is being used by over 5,000 ministers, teachers, and social workers. It is sent to the religious press and to editors of a selected list of daily newspapers and journals.

Courses and Publications.—The Department has issued other studies including study courses and a series of research bulletins. The last two publications are entitled: "Social Aspects of Coöperative Marketing" and "The Prohibition Situation." The last named was published serially in several hundred newspapers and five hundred editorials in city papers were published about it. This report was not intended as a survey of the entire field but took "soundings" of data commonly appealed to by "wets" and "drys" and made an impartial appraisal of available data. An appraisal was also made of national prohibition enforcement. It is regarded by many competent students as the outstanding piece of social research during the past two years and has had a wide acceptance. Its influence has exceeded any other study in this field since the publication of the steel strike report of the Interchurch World Movement.

INDIVIDUAL HOUSING

By James Ford

Executive Director, Better Homes in America

Purposes.—Better Homes in America is a national organization which through local committees aims to help American families to a knowledge of the ways in which housing conditions can be improved, and wholesome home life may be made available to all. Its aims may be summed up briefly as follows:

1. To put knowledge of high standards in house building, home furnishing and equipment, and home life within the reach of all citizens.

2. To arouse interest in the building of sound, attractive, economical single-family houses in which private home life may be possible; to encourage the reconditioning and remodeling of old houses and to encourage thrift for home ownership.

3. To promote general study of the housing problem and of problems of family life; to demonstrate each year the best types of house construction, home furnishings, and labor-saving devices for homes which are within the reach of families in moderate circumstances.

4. To encourage instruction in home economics and home life in the public schools and wherever advisable the construction of school practice cottages through which the girls and women of the community may receive continuous instruction in the ways of improving home life, and making household activities easier.

5. To promote the improvement of house lots, yards, and neighborhoods.

6. To extend knowledge of the ways and means of making home life more attractive and happier through the development of home music, home play, home art, and the home li-

brary, and to encourage special study and discussion of the problem of character building in the home.

Organization.—The Better Homes organization was founded by Mrs. William Brown Meloney in 1922 following a suggestion made by the late President Harding. It was reorganized on a national basis as an educational corporation for the public service in 1923.

Volunteer local committees act under the direction of national headquarters and annually demonstrate to their communities higher standards in housing and home-making, keeping always in mind that it is the family of modest means which the organization is seeking primarily to assist. During 1925, the movement reached to every part of the country and to Hawaii and Alaska. Two thousand American cities, towns, and rural communities, through local committees, brought this educational work to a higher degree of usefulness than during any preceding campaign. Each spring a week is set aside for simultaneous demonstrations all over the country of "better homes."

Model Houses.—Atlanta, Georgia, and Santa Barbara, California, shared in the award of 1925. In Atlanta special care was taken to arrange for educational work among the native white population, among the large negro element, and among those immigrants whose knowledge of American standards of housing and home life was slight. One home of four rooms, costing $2,150 and furnished for $750, was designed for occupancy by a negro family, the demonstration being in charge of a negro sub-committee. The apartment for an immigrant family was in a remodeled two-family house. Two school practice apartments were shown, one in an institution for negro girls, the other in a high school for white pupils. A fifth home was demonstrated, by a six-room frame house in good Colonial style, based on plans published in the *Plan Book of Small Houses*, a pamphlet prepared by the Better Homes Architects. The house cost $6,750; the attractive well-planted plot on which it stood was valued at $2,000. It was thus well within the reach of a family with an income of $3,000 to $4,000 a year.

Thousands of people visited these houses during Better Homes Week. Visitors were led through each house by hostesses who explained its advantages and distributed booklets containing lists of the furnishings of each room, with their costs and suggested annual budgets. An important feature of the Atlanta demonstration was a Home Builders' Clinic —a committee of bankers, builders, architects, and others—who could be consulted by prospective home-owners without charge.

In Santa Barbara also widespread coöperation was sought and secured from local organizations. The principal demonstration home contained six rooms on its one floor, well arranged. The lot was carefully planned and planted, and was valued at $2,212. The house itself cost $6,109. This house was furnished at a cost of $1,592. Each article of furniture was listed, with its price, in a booklet distributed to visitors.

Another home was of three rooms, built at a total cost of $1,544.90, and attractively furnished for $394.67, a total of under $2,000 for a family of very limited income.

A unit of three homes in one was built on a steep hillside, one dwelling on the street level, another above and back, and farther up the hill was a third, detached from the other two. The lower building containing two dwellings cost $6,360. The upper residence cost $2,100.

Another demonstration house was a five-room brick-veneer house valued at between $6,000 and $7,000, exclusive of the lot. Another was a four-room house built of adobe, the brick being made on the lot. It was valued at about $6,500.

School Practice House.—The Port Huron, Michigan, Better Homes Committee demonstrated a school practice house, built on city land as part of the regular school equipment, to be used as a permanent center for training girls in home-making methods. The Junior High School students carried out the whole project themselves, under the guidance of their teacher of civics. The Board of

Education appropriated $5,000 to build the house, and the students followed every detail of construction, after their plans were modified and approved by architects and a contract for the construction awarded. Committees of pupils chose the decorations and furnishings for the house. Very comprehensive educational programs were conducted during Better Homes Week in Port Huron, in addition to the demonstration of the house itself.

In fully 2,000 communities the local committees arranged for lecture and discussion programs on small-house architecture, furnishing the home, household equipment, home gardens, selection of books for the home library, or arranged contests for improvement of kitchens, living rooms, or for the beautification of home grounds and gardens. In addition to the promotion of local demonstrations, the National Headquarters of Better Homes in America through its contact with government departments and national organizations is able to provide local committees with information on any phase of the housing problem and the titles of publications which would be useful to them in coping with their local housing problems.

During the year 1925, the National office has prepared and distributed an illustrated *Guidebook* for the use of its chairmen, a *Plan Book of Small Homes*, a pamphlet on *Home Music and Home Play*, and has revised and reprinted an illustrated pamphlet of the U. S. Department of Commerce entitled, *How to Own Your Home.* To promote the instruction of school children in the art of home-making, the Research Department has issued a pamphlet entitled, *School Cottages for Training in Home-Making.*

SOCIALISM

By Algernon Lee

Educational Director, Rand School of Social Science

CHARACTERISTICS

Origin.—Modern Socialism dates from about 1848. Small in its beginnings and slow in its early growth, it endured severe persecution in many countries and steadily spread over the civilized world. By the beginning of this century it has become in Europe a power that had to be reckoned with. Although the Great War seemed for a time to have shattered its organization and was thought by many to have discredited its theories, it has since assumed even greater importance than it had in 1914.

Basis.—Socialism is to be regarded, not primarily as a theoretical system or scheme of social reorganization, but as a class movement growing out of the facts of capitalist society, which has developed a body of theory and a program to meet its needs. It comes into existence wherever there arises the system of large-scale machine production, with its tendency to concentration of wealth and to division of society into classes of capitalists and wage-workers. It is essentially a movement of the wage-working class, though supported by many individuals not of that class. It aims at the establishment of economic liberty, international peace, and social harmony through abolition of private ownership and control of socially necessary means of production and distribution, and the substitution therefor of public ownership and democratic administration, with production for use instead of profit.

Political Aspect.—Socialism is a political movement. Its conception of political action is a broad one, however, education and organization of the masses for self-reliant and intelligently directed use of the power of their numbers being held essential, while the winning of office is only a means to an end. Socialists do not regard political action, in the ordinary sense of the term, as sufficient; along with it must go the activity of labor unions, of coöperative societies, and of educational and cultural organizations.

Socialism is international because the capitalist system is international. It is, however, organized in national bodies, each autonomous in its field, all linked together through periodic international congresses and through the International Socialist Bureau, with its headquarters at Zurich, which do not exercise a binding authority over the affiliated parties, but have a strong directing and coördinating influence.

Socialism and Communism.—In earlier times these two words were often used interchangeably. Thus, the *Communist Manifesto*, written by Karl Marx and Frederick Engels in 1848, has always been regarded as an authoritative statement of the Socialist position. The words now designate two distinct and even hostile movements. Communism, as represented by the Communist parties of Russia and other countries and by the Communist International, with its headquarters at Moscow, originated as a "left wing" tendency within the Socialist movement during and immediately after the war, and resulted largely from the peculiar nature of the Russian revolution. Socialism is fundamentally democratic and seeks to achieve its aims by lawful and peaceable means wherever possible. Communists reject democracy in theory and practice, advocate the so-called "Dictatorship of the Proletariat," and hold that socialization of industry can be effected only by violent revolution. Wherever a Communist party exists there is constant and bitter conflict between it and the Socialist party.

ORGANIZATION

Party Names.—Socialist parties do not bear the same name in all countries. In Germany and several other countries the party is known as Social Democratic, in Belgium, Great Britain, Ireland, Australia and elsewhere as the Labor party. Readers of the American press must be warned that the French party commonly referred to in the dispatches as the "Radical Socialists" is not a Socialist party at all, "Socialistic Radicals" being the correct translation; also that the "Christian Socialist" party of Austria is definitely anti-Socialist as well as anti-Semetic.

Marseilles Congress.—The latest International Socialist congress was held at Marseilles in August, 1925. It concerned itself chiefly with the effort to assure world peace. While holding that only the socialization of industry in all the principal countries can, by eliminating the rivalry among national capitalistic interests, definitely put an end to the danger of war, yet Socialists consider that this danger can be minimized by reducing armaments, by making diplomacy open and subjecting it to the control of public opinion, by taking all occasions to promote mutual understanding among different peoples, and striving for amicable adjustment of each dispute as it arises. They rely above all on the organized working people to push this policy. The Marseilles Congress sharply criticized the League of Nations as it now exists, but hailed the Locarno Pact as a step in the right direction, and saw in the League a germ from which a real league of free peoples may be evolved.

BY COUNTRIES

Argentina.—The Socialists now have 18 seats out of 158 in the lower house and two in the upper. At the city election in Buenos Aires this year they got 57,000 votes out of 170,000, a gain of 8,000. The party has 10,000 dues-paying members.

Australia.—The Labor party increased its strength at the state election in New South Wales, held in May, and in Tasmania the following month. It has now a majority and controls the government in every state except Victoria. In the parliamentary election for the whole Commonwealth, which took place in November, the Labor vote was largely increased; but the new compulsory voting law brought out so many conservative stay-at-homes that the Labor party lost two of its former 29 seats.

Belgium.—The parliamentary election in April gave the Labor party 820,000 votes (39 per cent. of the total), as compared with 672,000 at the preceding election. The party now has 79 of the 187 seats in the lower house and 59 out of 153 in the upper, as compared with 68 and 52 in the old parliament. No party or combination of parties has been able to conduct the government without Socialist coöperation; the ministry formed in the early summer, and still in office at the close of the year includes Emile Vandervelde and four other Socialists.

Canada.—At the election held in October the Labor party gained nothing, but kept the two seats it already had in the Dominion parliament.

Chile.—A presidential election was held in 1925, at which the Labor candidate polled 71,000 votes out of 171,000. It is likely, however, that he received many votes which do not properly belong to the Labor or Socialist movement.

Czecho-Slovakia. — Socialism suffered a setback at the parliamentary election in November. In 1920 the total Social Democratic vote was 2,497,000. Since that time the Communist schism greatly weakened the movement. This year the Social Democrats polled 1,042,000 votes and the Communists 931,000. There are 48 Socialists and 42 Communists in the new parliament.

Denmark.—The Socialists are the largest party in the Danish parliament, though they have not a majority. In coalition with some other democratic and progressive elements they control the government, with the Socialist Theodor Stauning as premier.

France.—The parliamentary election of May, 1924, gave the Socialists 1,700,000 votes and 101 seats in the chamber. No party has a majority, and no coalition has been able to hold power without the consent of the Socialists. They drove Millerand from the presidency and overthrew the ministry of Poincaré. They gave their support to Herriot as premier, but preserved the independence of the party by not permitting any of its members to enter the Cabinet. Since the fall of Herriot the political balance has been unstable, and many expect a dissolution and new elections. The municipal elections in May, 1925, and the departmental elections in July brought very large Socialist gains, and the organized membership has been greatly increased within the last year.

Germany.—The first president of the German republic, the Socialist Friedrich Ebert, died early in the year. At the election which was held in March to choose his successor the Social Democratic candidate, Otto Braun, polled 7,798,000 votes out of a total of 26,856,000. There are 130 Socialists among the 485 members of the Reichstag. The German Socialists vigorously combat the Communists on the one hand and the Nationalists on the other. In domestic affairs they have been concerned largely with the defence of existing labor legislation against the attempts of the reactionaries to take advantage of the economic depression and force down labor standards. In the matter of international relations, they insist that Germany must fulfill its obligations under the peace treaties, while coöperating with the Socialists in other countries to obtain a revision of these treaties.

Great Britain.—The last general election, held late in 1924, increased the voting strength of the Labor party from 4,348,000 to 5,551,000, but reduced its representation in parliament from 191 to 151, out of 615 in all. This was due partly to the unusually large total vote, the habitual stay-at-homes mostly voting Tory, and partly to the fact that many former Liberals supported the Conservative candidates. It is again the leading opposition party, with the Liberals holding third place. The municipal elections in the summer of 1925 gave the Labor party large gains, both in the popular vote and in the number of members of municipal bodies. An outstanding fact in recent Labor party history is the adoption by an overwhelming vote, by the party conference at Liverpool in October, of a resolution definitely excluding Communists from membership.

Holland.—Parliamentary elections were held in July. The Social Democratic Labor party polled 706,000 votes and won 24 seats out of 100 in the lower house, as against 668,000 votes and 20 seats at the preceding election. The party is waging a lively disarmament campaign.

Japan.—Since the extension of the suffrage by the new electoral law a Labor party has been organized in Japan, but it has as yet had no opportunity to test its strength.

Latvia.—At municipal elections held in February and March the Social Democrats increased the number of their city councillors from 18 to 31. At the parliamentary election in October the Socialist vote rose from 242,000 to 260,000 and the representation in parliament from 31 to 33, out of a total of 100.

New Zealand.—The parliamentary election in November was unfavorable to the Socialist cause, the Labor party electing only 13 of its candidates, instead of 17 as before.

Sweden. — The Socialist premier, Hjalmar Branting, died in February, but was succeeded by another Socialist, Rickard Sandler. An outstanding achievement of his administration has been the reduction of the army by about one-third. The Socialists aim at complete disarmament, but not having a clear majority have not yet been able to carry their point so far.

Switzerland.—Both the municipal elections in the spring of 1925 and the parliamentary election in October gave considerable gains to the Socialists. Their representation in the national assembly rose from 43 to 49, out of a total of 198 seats.

Eastern and Southern Europe.—Under the Communist dictatorship in Russia, the Fascist dictatorship in Italy, that of Horthy in Hungary, and equally arbitrary régimes in Bulgaria and Rumania, there is little opportunity for the normal functioning of the Socialist movement on either the political or the industrial field. Many of the leading Socialists of these countries are in prison and many more have been driven into exile. The party nevertheless maintains its existence and strives as it can for the reëstablishment of political liberty.

United States.—This is one of the few countries in which Socialism as an organized movement is now weaker than it was at the close of the war. This is explained partly by the discouraging effect of the Communist schism, but largely also by peculiar economic conditions prevailing here. Concentration of wealth was for some years checked by "war prosperity," giving a new lease of life to small business men and temporarily restoring the opportunity for the working man to rise out of his class instead of having to rise or fall with it. Only when the tendency to concentration again becomes obviously strong can a rapid growth of Socialism again be expected. In the election of 1924 the Socialists joined with numerous labor unions and other elements in supporting the candidacy of the late Senator La Follette, hoping thereby to bring about the formation of a labor party somewhat on the British model. This hope was not realized. As the votes cast by Socialists cannot be distinguished from those cast for the same ticket by others, and as there was no general election in 1925, the Socialist voting strength can be only roughly estimated. The vote for Eugene V. Debs in 1920 was about 920,000. There is one Socialist in the present House of Representatives—Victor L. Berger of Milwaukee. The party headquarters is at 2653 Washington Boulevard, Chicago, and its national organ is the weekly *American Appeal*, published at that address. Other important Socialist papers are the *Daily Leader* in Milwaukee and the weekly *New Leader* in New York.

Necrology.—Death has been busy among the older generation of Socialists. Among the most prominent of those who passed away in 1925 were Hjalmar Branting of Sweden, Herman Greulich of Switzerland, Pablo Iglesias of Spain, and Henri Van Kol of Holland, each of whom has devoted a half century or more of intense activity to the Socialist and Labor movement of his own country and to the International; also Job Harriman, who was Socialist candidate for vice-president in 1900 and had in his later years been absorbed in the coöperative movement; and George D. Herron, who played an active part in the American Socialist movement for several years about the beginning of this century.

DIVISION XXV
IMMIGRATION AND RACES

RACE CONDITIONS IN THE UNITED STATES

By Robert S. Foerster
Professor at Princeton University

General.—The end of the first quarter of the new century supplies a most convenient observation point from which to note the composition of the population of the United States. It is true that we have not for the year 1925 any exact measure of the elements of this population. Such a measure does exist, however, for the year 1920, and it is possible to indicate in what principal ways a 1925 cross section, could we have it, would differ from that of 1920.

No other great country can measure the decennial changes of its population as far back as the United States. No other great nation, through its expanding and formative years, has recorded so fully the stages of its growth. All the great nations of the world are composed of diverse elements, but in no other great people of mixed stocks is it possible to picture at equal intervals the stages of growth. The United States Census Bureau is in fact a laboratory in which the people are periodically measured and appraised.

The total count of persons in the population in 1920 was 105,710,620. Of these 94,820,915 were white. Slowly, decade after decade, the proportion of white has been rising; it was 88.9 per cent. in 1910 and became 89.7 per cent. in 1920, the highest in our history. The principal nonwhite elements were the negroes, who were 9.9 per cent. of the population; the American Indians who were 0.2 per cent.; the Chinese and Japanese who together were about three-quarters as numerous as the Indians.

Europeans in the United States.—We are for the most part a nation composed of European white races. In the ten years ending in 1920 our native population grew by 13,333,548 or 17 per cent., and our foreign born population grew by 404,806 or 3 per cent. (foreign born whites grew by 367,209). But these figures for growth fail wholly to show the extent to which our population is still of recent foreign stock. The ten years before 1920 embraced the years of the World War. Beginning in 1914, immigration fell off because of the need for men in the fighting countries and because of the prohibitions attached to emigration from those countries; many aliens departed from the United States on being called to the colors in Europe; the drift toward the resumption of emigration from Europe on a great—perhaps an unprecedented—scale, after the War, was thwarted by new restrictions imposed upon immigration by the United States. In consequence the foreign-born stock in the United States increased but little in this decade, and in 1920 this stock constituted an unusually small proportion of our total population.

Parentage.—For a better measure of the sustained importance of the foreign element in our race stock we must look to the figures for parentage. In 1910-20 the white population born in the United States increased by 12,721,749 (18.6 per cent.). Of these 8,933,382 had American-born parents, but 2,778,228 had foreign-born parents and 1,010,139 had one foreign and one American parent. In other words, at the end of a decade in which foreign immigration seemed almost negligible, the increase of that part of our population having at least one parent foreign born was actually 44 per cent. as great as the increase of that part having both parents native.

These figures dealing with our recent growth have been given prominence because they show that, even in a decade of small immigration, the foreign race factor may contribute heavily, through births, to our next generation.

Northern and Southern Europe.—Most of the foreigners in the United States in 1920 represented an immigration that had come before 1910, and largely originated in Europe. The total number of foreign born was 13,920,692 and of these 11,882,053 originated in Europe. Northwestern and Central Europe supplied more than two-thirds of all who had come from the continent of Europe, while Southern and Eastern Europe together supplied less than one-third. In other words, our foreign population of 1920 was for the most part of the same origins as that of the early days of our settlement.

The British Isles led, with Germany a fairly close second; and these two together included about a third of all our European immigrants. Italy, however, had in 1920 nearly as many representatives as Germany, while Russia and Poland followed closely after. These three were the outstanding countries of the "newer" immigration. Austria, Hungary, Czechoslovakia, Jugoslavia, Finland, Greece were heavily represented, and loomed much larger beside the Scandinavian countries than they did in earlier years; yet Sweden, Norway and Denmark were still represented in 1920 by considerably more than a million immigrants.

Furthermore, practically all these Europeans of both the "newer" and the "older" immigration are of closely related stocks. Among Nordic, Celtic and Mediterranean races, the three great races of Europe, differences can certainly be pointed out, but they are all differences of a less emphatic sort than those that mark off the three European races and their mixtures from the other primary races of the earth.

Nearly nine-tenths of our population is of European white stock. In other terms, the ancestors of nine-tenths of our population lived in Europe as late as the time of the discovery of America, and for the most part lived there much later than that epoch. Biologically we are European, and our civilization is conditioned largely by our biology and by the culture developed by the white races in Europe.

Third Generation Stock.—It is easy to exaggerate the racial importance of the immigrants from Southern and Eastern Europe in the United States. Their numbers, it is true, look substantial when placed alongside those of our immigrants from the rest of Europe. They are, however, to-day only a first-or-second-generation stock while our immigrants from the rest of Europe are not to be thought of as merely a first-generation stock, but as essentially the same in kind with the great mass of our "native white" stock. In other words, it was not Greeks, Italians and Russians but largely British, Irish, Germans and Scandinavians (or their descendants) who were the parents of our present native stock.

Distribution in U. S.—Our foreign-born population is to be found chiefly in those parts of the country where the white population as such is most numerous. Extremely few foreign born are in the South Atlantic and East South Central States; and it is chiefly immigrants from Mexico who are to be found in the larger number of foreign born living in the West South Central States. At the head of all divisions are the Middle Atlantic States, where in 1920 lived a full third of all our foreigners. Next in order come the East North Central States, the New England States, the West North Central, and the Pacific.

Each nationality of foreign born, however scattered its representatives, has settled by predilection in some state or states. The Oriental races have been on the Pacific Coast, the

Mexican immigrants in the South West. Immigrants from England, Scotland and Ireland are largely in New York, Massachusetts and Pennsylvania; immigrants from Germany, in New York, Illinois, Wisconsin, Pennsylvania and Ohio; those from Norway and Sweden in Minnesota, Wisconsin, Illinois; those from Italy in New York, New Jersey, Pennsylvania and Massachusetts; those from Poland, Russia and Lithuania in New York, Pennsylvania and Illinois; those from Canada in Massachusetts, Michigan and New York; those from Czechoslovakia in Pennsylvania, Illinois and Ohio; those from Finland in Michigan, Minnesota and Massachusetts; those from Greece in New York, Massachusetts and Illinois; those from Switzerland in California, New York and Ohio.

Immigrants from Canada living in the United States in 1920 numbered considerably more than a million. By far the greater part of them were of European origin; some were of stocks that had been established in Canada for several generations. By their coming the white factor of the population of the United States was measurably increased.

Intermarriage. — European white stocks have always intermarried in the United States, less in the first generation (the immigrating) than in subsequent generations. Statistical data are but partial and occasional but, such as they are, attest the fact beyond doubt. When the foreign accent and foreign customs disappear, when the upbringing is purely of this country, no barrier continues between different European white stocks. In this sense we are becoming more and more homogeneous as a people.

Negroes.—The tenth of our population remaining after the white stocks are removed from the picture is principally negro. When the century began, negroes numbered 8,833,994; in 1920, they numbered 10,463,131. While the great majority live in the Southern States, their increase in those states has been proportionately much less than in the North and West. Actually there has been a large migration from the South into the rest of the country, and this has been on a scale unprecedented in our history. The number of negroes who were living in the North in 1920 fell but little short of a million and a half.

Partly because of migration to the North and partly from other causes (such as a falling birth rate while the death rate has not much changed) the negroes present in the Southern States have not increased so fast as the whites in the same states. In the East South Central division of states, an increase among the whites in 1910-20 was accompanied by an actual decrease among the negroes. And, except for West Virginia, every Southern state had in these years a greater increase of whites than of negroes, if it did not actually have a decrease of negroes.

Our census authorities, following a common usage, regard persons born of crosses between whites and blacks as belonging to our negro stock. These persons (mulattoes) amounted to 15.9 per cent of the total negro stock in 1920. In counting mulattoes, so much depends on the personal judgment and care of the enumerators, that close accuracy of the final figure is not in question. Since a still higher percentage was reached by the census authorities in 1910, the figure of 1920 is probably conservative. A higher percentage of mixed stocks were found in the Northern and Western States than in the Southern.

Indians, Chinese and Japanese.—There were three other non-white stocks separately listed by the Census. American Indians were recorded as 244,437, Chinese as 61,639 and Japanese as 111,010. The Indians were slightly fewer than in 1910. The Chinese were considerably fewer—their decline had been continuous since 1890, when they numbered 107,488. The Japanese were much more numerous than at any previous Census—their increase had been continuous since 1890, when they numbered only 2,039.

Latin Americans.—More numerous than our American Indians and the Chinese and Japanese taken together, are our immigrants from Mexico, Central and South America. They numbered more than half a million. While nearly all of them were listed by the Census as white, they generally belong to the same great race stock as the American Indians, often, however, with a white infusion. A very large majority come from Mexico. Consistency would require either that we regard our half-breed and mulatto population, as enumerated in the Census, as white, or that we classify our Mexican and other South American immigrants with American Indian stock rather than with our stock of European racial origins.

In general it can be laid down that European whites and African negroes, with an admixture of other primary stocks, constitute the population of the United States as revealed in the Census of 1920.

What now are the principal changes in our population that have come since 1920? While the changes cannot be measured accurately today, their drift is fairly clear.

Movement of Population.—The population as a whole has grown. The estimate of the Bureau of the Census puts it at 113,493,720 in 1925 (a figure which merely assumes a continuance since 1920 of the rate of growth found in the ten previous years).

Many immigrants of European origin have returned to Europe, as a rule only for visits. Their going is a reminder that between 1900 and 1920 (or certainly 1915) our immigration was very large. Many found it inconvenient to go away during the War. Many, after the War's ravages, are returning to look after relatives and property. Some, enriched, are returning to Europe to live.

From Europe immigration has continued, but at a reduced rate of flow. The new quota legislation has materially limited our immigration and now favors especially those races that had come before 1890. Its effect will be to strengthen that sector of our white population which is of Northwestern and Central European origin. In the fiscal year ending June 30, 1925, the net gain of our population through immigration—excess of arrivals over departures—was 232,945.

To this immigration must, however, be added a material increase in illegal immigration, somewhat by sea but mainly across the Canadian and Mexican borders. This illegal immigration has unquestionably been large during recent years. Those who compose it derive principally from European countries.

Partly as a consequence of the restrictions placed by our laws on immigration from Asia and Europe, there has been an increasing shift of peoples within our own hemisphere, and principally on our own continent. On the one hand, negroes have continued to move from the Southern states of our country into the North. On the other hand, immigrants have come in increasing numbers from Latin America and the West Indies, but in particular from Mexico. Should this immigration continue without abatement it would undoubtedly add materially to the strength of a race element in the United States that is not closely related to our predominant stocks of European or African origin.

SELECTION AND EXAMINATION OF IMMIGRANTS

By Arthur E. Cook

Assistant to the Secretary of Labor

The day has passed in the United States when an alien can enter the country and remain for any great length of time without measuring up to certain standards which we, the people of the United States, have determined are necessary for the good of the country. It is possible, because of statutes of limitations applying to a few of the offenses specified in the immigration laws, for an alien occasionally to evade inspection and detection long enough to make deportation impossible, but to avoid such detection for a sufficient period such an alien would have to be physically, mentally, morally and economically of such condition as not to attract the attention of State or Federal officers, or of citizens who felt their own rights, privileges or opportunities abridged by his presence. Aliens who can thus successfully avoid detection are not usually of a type who would deliberately plan entry into the United States in any other manner than that provided by law.

Exclusions.—The laws, and the machinery of the federal government, are constantly being improved so as to more successfully accomplish the purposes of immigration restriction; restriction not only by numerical limitation, but with regard to the classes who may be admitted. The exclusion list constantly grows. In an analysis of the Immigration Laws published by the Department of Labor twenty-four classes of aliens generally excluded are listed. The purposes of excluding these several classes might be said to be summarized for the welfare of the country under five heads: (1) to protect the national health; (2) to reduce crime; (3) to protect political institutions; (4) to promote economic prosperity; and (5) maintain the racial characteristics of the nation.

Examinations.—The medical examination of aliens coming to our shores either for temporary stay or permanent residence is made by the United States Public Health Service. Results are reported to the Immigration Service which acts upon the information in accordance with law.

There has been a constant demand expressed in successive laws for more care in the admission of those who are to become our compatriots and neighbors. Following a definite policy the physical and mental examination has been made more and more rigid in order to insure that those who enter the United States bring sound minds in healthy bodies and as such they are being universally welcomed.

The new law which went into effect July 1, 1924, has now had a trial of more than one year. It has allowed more thorough examinations to be made, even better than under the previous quota law, because it has insured a steady flow that replaced the wild rush at the beginning of each of the first five months of the fiscal year, and infinitely better than were possible when the rush was limited only by the capacity of the steamers. These human avalanches engulfed the resources of immigration stations and beat down the physical powers of medical officers in a way that made regular and careful work exceedingly difficult. All this is changed much for the better and examinations are now made with comfort for the immigrant and a standard of details that is possible only with ample facilities and a highly trained, efficient medical staff, with sufficient time to do thorough work.

At present a great majority of those passing our immigration stations receive a medical examination that is intensive or one comparable to a periodic overhauling by a family physician or a life-insurance examination. In addition, there is an examination in order to weed out those mentally defective or having even the beginning of insanity or nervous diseases. It is a huge task when the numbers, even under the present limited immigration, are considered. For the fiscal year ended June 30, 1925, the Public Health Service reports that 545,472 aliens were examined, of whom 25,226 were certified as having mental or physical defects. Of these 1,975 were serious or "A" certificates which note mentally affected or loathsome and contagious diseases; 14,759 were Class "B" certificates, reporting conditions that may affect the ability of the individual to earn a living and so be a possible cause of his becoming a public charge; and 8,492 were Class "C," denoting minor ailments.

Seamen.—In addition to passengers coming here for temporary or permanent stay, all alien members of crews of vessels are examined mentally and physically by the Public Health Service and these during the twelve months mentioned amounted to the huge total of 854,915. Although the stay of these sailors is limited, the Public Health Service states that they were examined with the almost the same minute care, with the result that 1,247 were certified under Class "A," 574 under Class "B" and 268 under Class "C."

Significance of Certification.—The rendering of Class "B" and "C" certificates by Public Health physicians does not indicate that the persons so certified are mandatorily excluded from the United States. The work of the Public Health doctors assigned to immigration inspection is carefully performed, with the result that in a large majority of cases of immigrants past the age of 55 a certificate of senility is rendered—meaning that the age of the persons is a condition which may affect the ability of the individual to earn a living. When all the surrounding circumstances are taken into consideration, there is frequently no justification either for the officers at the port or for the Department of Labor, when such cases come before it on appeal, to exclude such aliens merely because of the medical certificates. Usually it is found that such aliens are coming to sons or daughters, American citizens, who are financially able and willing to assume the care of the old people. There are numerous other causes, such as deformity, hernia, pregnancy, less than normal function, loss of member, etc., for which medical certificates are rendered. When, however, considered in connection with the other facts in the case, it is often quite apparent that such "deformities," "loss of member," etc., would in no wise affect the ability of the alien to earn a living. For instance, if a jeweler, bookkeeper, or any other person engaged in occupations of a sedentary nature were to be certified for loss of a leg, it could hardly be considered that such defect would impair his earning capacity. In fact, one of the officers in the principal districts has stated that over 90 per cent. of the medical certificates rendered might be considered in the nature of marks of identification.

Criminals.—As in the case of alien feeble-minded and insane, many of the individual States complain of the burden of expense by reason of alien criminals confined in public institutions. If our immigration laws means what they say, that no aliens of this class shall be admitted, and the inspection machinery actually functions 100 per cent., then there would be no criminals among our foreign-born population, except as we made them after arrival. Yet we find many persons of foreign birth behind bars in America. In his book *Selective Immigration* (published October 15, 1925) Honorable James J. Davis, Secretary of Labor, in the chapter, "The cost of poor immigrant stock" discusses the problem at some length. He says, "In 445 of our federal custodial institutions, including those for the insane, feeble-minded, epileptic, blind, deaf, tuberculous and paupers, there is a population of some 210,835. The percentage of foreign-born in the total population is 14.7. Using this percentage, there should have been some 25,366 foreign-born inmates in these institutions. Actually, there were found 35,612." Or compared with the population as a whole "the native-born contributed 93, and the foreign-born 140." Theoretically, if all defectives were excluded by the department's tests, the foreign-born contribution should have been zero and the entire population of custodial institutions native born! Dr. H. H. Laughlin in testimony before the Committee on Immigration and Naturalization suggests a remedy: "If the Federal Government had to maintain all of these inadequates at its own expense, there would be more poetic justice in the whole situation. As the matter now stands, the Federal Government has the authority in relation to immigration, whereas the several State governments have the responsibility and expense of caring for dependent immigrants and their children, who have slipped into the United States through the federal sieve."

The information just recited is not a reflection on those at present charged with the administration of our immigration laws. In often repeating the necessity of more careful selection and examination, Secretary Davis brings to light some important results of laxity in the past. When immigrants were coming in at the rate of a million or more each year sufficiently close examination was not given. With restricted immigration more detailed inspection is possible. During the fiscal year 1925 the immigration service refused admission to 159 aliens because of insanity, epilepsy, mental defects, etc.; 345 for physical defects; 562 afflicted with loathsome or dangerous contagious disease; 3029 as likely to become public charges; 523 (over 16 years of age) because illiterate; 98 as belonging to immoral classes; 251 criminals; 188 under Chinese exclusion law; 452 contract laborers.

Enforcement Problems. — Greater difficulty is experienced in enforcing the immigration laws on the land borders than at seaports. By proclamation of the President (January 12, 1925) the following aliens are permitted to cross the borders into the United States without passports or documents of any kind: "Citizens of St. Pierre and Miquelon and French citizens domiciled therein; citizens of Canada, Newfoundland, Bermuda, the Bahamas, and British possessions in the Greater Antilles, and British subjects domiciled therein; citizens of Mexico, Cuba, Haiti, San Domingo. Such persons may enter the United States temporarily from any of the countries named in this paragraph, or pass in transit through the United States from any such country—to any other such country." The above refers, it will be noted, to so-called "non-immigrants." The quota law excepts from numerical limitation also, immigrants, natives of Canada, Newfoundland, Mexico, Cuba, Haiti, Dominican Republic, and the independent countries of Central and South America. The latter class of immigrants, however, are required to possess immigration visas. The purpose of the arrangement is commendable, but without some method of alien registration, it adds to the difficulty of selection and examination. So much so that Congress appropriated $1,000,000 especially for a land border patrol. During the fiscal year 14,669 aliens were turned back by the patrol; 13,550 were referred to local immigrant inspectors for further examination; 104,073 freight and passenger trains bearing 1,553,000 passengers were examined; 416,976 automobiles and motor busses carrying 1,535,650 passengers, were stopped and examined.

Alien seamen are subject to the same physical examination upon arrival as are visitors to the United States. During the year immigration officers at ports boarded 32,194 vessels on which were examined 1,004,226 alien seamen. Of this number 1,720 were certified by the Public Health Service for loathsome or dangerous contagious diseases, and 1,595 were removed to hospitals for treatment.

Selection. — Very few of the immigrants today are "selected," because the policy of the Government as expressed in legislation is to discourage prearranged immigration. During the last year of and the three years following the Civil War, the Government did encourage immigration, and sanction arrangements for prearranged employment. But the Alien Contract Labor Law makes it a crime for any person or corporation in the United States to induce immigration by offers of employment. There is one exception to this general rule by which skilled labor may be induced to immigrate when labor of like kind cannot be found unemployed in the United States. To import such labor the prospective employer in the United States first obtains a permit from the Secretary of Labor. This permit is granted upon official verification of the inability of the person or firm desiring to import the labor to secure it in the United States. Most of the selection accomplished, therefore, is among already intending immigrants, by way of examination, for immigrants must obtain passports from their respective Governments before visas will be given.

The nearest to selection the present laws afford, aside from the exception in the Contract Labor Law regarding skilled labor, is found in the privilege of an American citizen to secure a non-quota status for his wife and unmarried children under 18 years of age and the similar right of a citizen to petition for preference status within fifty per cent. of quota limits for father, mother, husband and unmarried children under 21 years of age.

Admissions.—The total number of

aliens admitted during the fiscal year was 458,435, of which 60,203 were classified as "non-immigrant," persons not coming for permanent residence. The number of immigrants charged to the quota were 145,971; non-quota immigrants 250,912, of which 175,865 were natives of Canada, Newfoundland, Mexico, Cuba, Haiti, Dominican Republic, Canal Zone or independent countries of Central and South America; 1,475 were ministers of religion and their families; 261 professors of colleges, academies, seminaries, universities, and their families; 1,462 were students over 15 years of age coming to schools approved by the Secretary of Labor.

As already stated 3,029 aliens were refused admission on the grounds that they were likely to become public charges, but money aggregating $22,357,977.00 was shown to inspectors by aliens admitted. Thirty-five per cent. of the immigrants had less than $50 each; only 153,020 claimed to have paid their own passage; 135,769 admitted passage paid by relatives and 5525 that their way was paid by others than relatives; 224,324 came to join relatives; 28,256 to join friends. Those coming neither to friends nor relatives numbered 41,724.

The permanent alien population of the United States was increased by 232,945 — 225,490 having departed during the same period. Of this net immigration 71,561 came from the Eastern hemisphere (principally Europe) and 129,935 from the Western (mainly Canada and Mexico). "The total real immigration" according to the 1925 report of the Secretary of Labor "was 294,314, against 706,896 for the previous year, or a decrease of 58.4 per cent. Old World total immigration decreased 77.7 per cent. and New World declined 37.9 per cent. Because of the heavy return to Europe during the fiscal year the net gain from the New World nearly doubled that of the Old."

Expense.—An incident of the selection and examination of immigrants is the financial cost to the government. The expenditures of the immigration service totaled $5,231,689, while revenue from the same source amounted to $4,189,247.50. This revenue does not include the application and visa fees paid to American Consuls, amounting to $10 each for every visa granted. Principal items in the revenue schedule were head tax, $3,098,411.15; fines, $613,046.56; permits to reënter, $199,157.38; bonds forfeited, $109,350.00; care in immigration stations and treatment of aliens in hospital, $161,811.25.

THE QUOTA SYSTEM

By Arthur E. Cook

Assistant to the Secretary of Labor

Purpose.—In developing the so-called "quota" system of limiting immigration, the United States undertook to solve a problem which has never before in the history of the world been solved. Four years in the period of the world's history is a very short time to judge what effect the system will eventually have upon the life of the nation, but for the present it is accomplishing exactly what its proponents desired.

The problem is to maintain the racial characteristics of the population [see Race Conditions in the United States], and at the same time not suspend immigration entirely, it being generally considered that so drastic a measure would result in untold hardship, and also prevent the admission of certain man-power still needed from outside sources for our industries. The influx of an overwhelming number of aliens of different racial characteristics is represented by history to have been responsible for the downfall of the Roman and other empires; yet no movement of people any place, nor at any time can compare in number or rapidity with the migrations from Europe to the United States.

Place of Birth.—The theory of the quota plan is that by limiting immigration from all countries in direct proportion to the numbers of the nationals of each already here a cross section of the sum total of immigrants admitted during a year will exactly represent the racial characteristics of the present population. For the purpose of allotting the quotas, therefore, the place of birth was selected to determine the quota to which a particular immigrant would be charged, rather than the nation to which he might owe allegiance. In most cases the result is the same, but in some instances, by reason of changing political boundaries, and the very migratory nature of man, there is a difference. Therefore, a subject of Greece may be charged to the quota for Turkey, because born in the area over which Turkey had jurisdiction. However, while this may seem illogical in special instances, it is the only basis upon which the determination could be made because nationality is far less indicative of race than the geography of birth.

Basis.—The year 1925 was the first quota year under the Act of 1924 which limited admissions (of defined quota immigrants) to two per cent. of the persons accredited to their country in the census of 1890. The prior laws of this character (the first passed in 1921) used the basis of 1910, but for reasons which are stated below Congress deemed it advisable, pending a more scientific determination, to base admissions upon nationality of residents of the United States a generation ago. The quota act of 1921, as amended by resolution of 1922, permitted the entrance in the fiscal year 1924 of 706,896 immigrants. The quota law limited so-called quota immigrants to 356,995, the excess over quota limit being accounted for by the admission of "non-quota" immigrants, and immigrants from non-quota countries. By reducing the percentage to two, and the census basis to 1890, the quota limit was brought down to 164,667.

The further reason for going back to 1890 was assigned on the theory that relatively heavy incomings from southern and eastern Europe during the past twenty or thirty years radically changed the racial characteristics of our foreign-born population as compared with native white stock. Therefore any basis subsequent to 1890 was represented to be discriminatory against the races which originally founded the nation and developed it to that time; some consideration ought to be given to the national origin of all the American people as well as to the origin only of persons of foreign birth.

The 1890 census was therefore selected to be used pending a mathematical calculation of the "national origin" of all the residents of the United States in 1920. Beginning with the fiscal year 1927, a national origin basis will be established on a norm of 150,000 total admissions; each country to have an allotment reckoned on the proportion to 150,000 which the number of persons of that national origin bears to the total population of the United States.

Admissions Outside the Quota.—As already intimated, the limit fixed by quotas is not a limit placed upon all admissions to the United States, nor, in fact, upon all immigrants. During the fiscal year 1925 458,435 aliens were admitted, of which number 294,314 were of the immigrant class; 145,971 were admitted under the quota. The quota itself, 164,667, was not filled by 18,696; 148,243 were admitted as immigrants not restricted by the numerical limitation; 18,607 aliens who applied for admission without having the proper visa were debarred, and 2,723, deported. Practically all these cases represent rejections because of quota limitation. Of course, realizing the futility of trying to enter probably hundreds of thousands of "would-be" immigrants never left their homes.

The exceptions to the quota provision, responsible for the admission of so many more aliens than accounted for in the quota, are those not required to have immigration visas and those classified as "non quota" immigrants. The former group comprises: (1) government officials, their family, attendants, servants, and employees; (2) aliens visiting the United States temporarily as tourists or for business or pleasure; (3) aliens in continuous transit through the United

States; (4) aliens lawfully admitted to the United States who later go in transit from one part of the United States to another through foreign contiguous territory; (5) bona fide alien seamen serving as such on a vessel arriving at a port of the United States and seeking to enter temporarily the United States, solely in the pursuit of their calling as seamen; (6) aliens entitled to enter the United States solely to carry on trade under and in pursuance of the provisions of a present existing treaty of commerce and navigation.

"Non-quota" Immigrants. — Such are:—(1) An immigrant who is the unmarried child under 18 years of age, or the wife, of a citizen of the United States who resides therein at the time of the filing of a petition under section 9. (2) An immigrant previously lawfully admitted to the United States, who is returning from a temporary visit abroad. (3) An immigrant who was born in the Dominion of Canada, Newfoundland, the Republic of Mexico, the Republic of Cuba, the Republic of Haiti, the Dominican Republic, the Canal Zone, or an independent country of Central or South America, and his wife, and his unmarried children under 18 years of age, if accompanying or following to join him. (4) An immigrant who continuously for at least two years immediately preceding the time of his application for admission to the United States has been a minister of any religious denomination, or professor of a college, academy, seminary, or university, and who seeks to enter the United States solely for the purpose of carrying on that vocation, together with his wife, and his unmarried children under 18 years of age, if accompanying or following to join him. (5) An immigrant who is a bona fide student at least 15 years of age and who seeks to enter the United States solely for the purpose of study at an accredited school, college, academy, seminary, or university, particularly designated by him and approved by the Secretary of Labor, which shall have agreed to report to the Secretary of Labor the termination of attendance of each immigrant student; and if any such institution of learning fails to make such reports promptly the approval shall be withdrawn.

Proposed Extensions.—In his Annual Report for 1925 the Secretary of Labor recommends that the quota provisions be extended also to persons born in the countries of this hemisphere now specially excepted. This because, he points out, "by failing to impose a quota upon these countries, we are in the position of barring the front door to America while we leave the back door wide open." Also, he says, "In practice we have found that these exceptions make for evasion and violation of the law, and assist the operations of alien smugglers, bootleggers of humanity."

Relation to General Laws.—While the terms of the quota act are so broad as to make available quotas for aliens born in and of the races inhabiting the "barred zone," its provisions are in addition to and not in substitution for those of the general immigration laws. Therefore aliens inadmissible for any reason under other laws cannot be admitted even though having appropriate quota allotment. Hence, while Japan has the nominal minimum quota of 100, immigrants under that quota must be of races eligible to citizenship, e.g., the son of German parents born while visiting Japan would, if an immigrant to the United States, have to be charged to the quota for Japan. An Oriental coolie could not be admitted as a quota immigrant even though no other demand were made upon the quota available to his country.

Preferences.—Within the quotas allotted, preferences up to fifty per cent. are given in favor of a quota immigrant who is the unmarried child under 21 years of age, or the father, mother, husband, or wife of a citizen of the United States who is 21 years of age or over, and also to a quota immigrant who is skilled in agriculture, and his wife and dependent children under the age of 16 years if accompanying or following to join him. Agricultural preferences, however, do not apply to immigrants of any nationality the annual quota for which is less than 300. No one of the preferences provided has any right of priority over another.

SELECTION AND EXAMINATION OF IMMIGRANTS ABROAD

By Arthur E. Cook

Assistant to the Secretary of Labor

Precedents.—The suggestion that aliens intending to emigrate to the United States be required to submit to thorough examination before receiving permission to embark is not a matter of recent years. Published hearings of the Committee on Immigration and Naturalization of the House of Representatives show that the subject has been several times considered in connection with reforms in immigration policy. Several of the countries of South America now require of immigrants documents approved by their consular officers including: (1) medical certificate of a designated physician; (2) certified police record; (3) certificate of "ability to work"; and (4) evidence that alien has not been a public charge.

Humanitarian Argument.—The Secretary of Labor, who has during the whole of his term of office stressed the need for transferring the inspection machinery of the Public Health and Immigration Services to foreign ports endeavored to have his views expressed in legislation during the sixty-eighth Congress. On the grounds of humanity alone, he has pointed out: "One great result of moving our inspection machinery abroad to make selections among the applicants for admission would be to end the heart-rending scenes which are every day being enacted at Ellis Island and the other ports of entry. So long as under the law we admit foreigners to this country we could end all of these horrors if selection were made on the other side and immigrant stations would be transformed into gateways of welcome, devoid of the harshness of official delays and sorrows of disappointment. So long as the United States is to admit foreigners we should have a system that would function to bring us the best that we can get from abroad, but to limit the number of undesirables who seek entry and prevent 'dumping' of such classes by foreign governments."

Economic Argument.—Another argument in favor of selection abroad is based entirely upon economic grounds, that "we cannot afford to burden the American economic structure with man power we do not need, which might easily be used in time of industrial depression to undermine the American wage scale and the American standard of living." By keeping some kind of check upon the occupations of applicants for visas, their destination in the United States, and the relative employment situation, an overabundance of labor destined to a particular locality and occupation could be discouraged with resulting advantage not only to American workmen, who shall have our first consideration, but to prospective immigrants as well.

Anarchists.—Upon the authority given to American Consuls by the Immigration Act of 1924 to refuse visas, a number of anarchists, members of communist parties, etc., were prevented from coming to the United States. The law prohibiting the admission of aliens who believe in the overthrow by force and violence of organized government is constantly being enforced through the refusal of permission to come to the United States to persons of little or no influence; but when a person of some prominence, either by position or by reputation, is affected, then a storm of protest breaks. An outstanding example of this type of oversea "selection" is the case of Shapurji Saklatvala, Parsee member of Parliament of Great Britain, who expected to come to the United States as a delegate to the Interparliamentary Union. A visa was granted by the American Consulate General at London as a matter of course, but when utterances of this member of parliament indicating that he was a member of one of the excluded classes were brought to the attention of the Secretary of State the visa was cancelled, and Shapurji Saklatvala was unable to proceed. It would be difficult to enforce a law of any kind in the United States on any other basis than equally against all who come within its provisions.

Families.—This episode is a strong argument in favor of Secretary Davis' contention that certain of the provisions of the immigration laws can only be enforced through selection and examination abroad. American officers permanently stationed in the district from which an intending immigrant starts must necessarily have facilities for determining history, reputation, and condition, not only of individuals, but of the families of individuals, not available at a port of entry. "Frequently," says the Secretary of Labor, "alien families deliberately come one or two at a time and establish themselves here in order to establish a basis for a plea of mercy and consideration for the final member who, when he or she arrives, is found to be mandatorily excluded because of mental or physical condition. Often the head of the family has become an American citizen before he has permitted an insane or feeble minded child to apply for admission." With full examination abroad this situation would be impossible.

Beginnings.—The plea of the Secretary of Labor that "these examinations should be made by American officers on the authority given to American Consuls to refuse visas to those who do not measure up has not yet received legislative response. The reason is attributed to the belief on the part of Congress that foreign nations would resent legislation making such examinations compulsory. Failing in the securing of legislation requiring all applicants for visas to be examined abroad the Secretary of Labor proposed to the Secretary of State and the Secretary of the Treasury (for the Public Health Service) that endeavor be made to secure through diplomatic channels the consent of one or two foreign governments to try the plan experimentally for at least three months. The Government of Great Britain and the Irish Free State readily agreed and on July 8, 1925, seven immigrant inspectors and as many public health physicians left the United States to supervise the immigration business at the consular offices located in London, Southampton, Liverpool, Glasgow, Belfast, Dublin and Queenstown.

Actual inspection began on August 1, 1925. The total number of quota visas which may be granted in one month to natives of Great Britain and northern Ireland is 3,400, and of the Irish Free State 2,856. While the number who may come to this country is increased by the non-quota classes, quota departures from the British Isles are slightly less than the quota limit because of allotment of a small portion of the quota to consulates at places other than in the Islands, so that the actual figures may vary slightly. It is significant of the practicability of the plan, however, that during the trial period no immigrant passed by Immigrant and Public Health Service has been found inadmissible when finally passed upon by officers on this side who verified their status upon arrival here.

There is no indication at present of the official action which will be taken upon the result of this administrative experiment either toward the countries where it has been conducted, or elsewhere. It is intimated that the results are as gratifying to representatives of the foreign governments concerned as to officials of the United States and the Secretary of Labor will continue his effort to have the plan written into permanent law. Of necessity a larger foreign service of the United States would be required, but the cost of administration of the immigrant laws at home would be decreased. Only experienced inspectors, it is officially stated, would be considered for this foreign service should the overseas examination system be extended or become permanent.

PROBLEMS OF IMMIGRATION

By Theodore G. Risley
Solicitor, Department of Labor

Deportation of Aliens.—The statistics for the past two years show a marked increase in the number of aliens deported. For example, in 1892, 637 aliens were deported for being unlawfully in the United States. In 1900, the number was 356; in 1905, 845; in 1910, 2,695; in 1915, 2,564; in 1920, 2,762; while in 1924, the figures had mounted to 6,409 and for the year ended June 30, 1925, there were 9,495 aliens deported. Of this latter number 1,914 were deported to Canada and 1,828 to Mexico, the remainder, with the exception of a small number of South Americans, Asiatics and Africans, being deported to European countries. The aliens deported should be distinguished from those rejected for various causes at United States ports of entry for the year 1925. Of the latter class there were 25,390 rejected during the year 1925, as against 30,284 rejected during the year 1924, and 20,619 in 1923.

Prevention of Entrance.—Large numbers of aliens were prevented from entering the United States unlawfully during the year 1925 or detained temporarily and in some cases arrested on warrant through the efforts of the newly created Border Patrol Service of the Department of Labor. This patrol service was created by Congress on May 8, 1924 (43 Stat. 240), and the power of patrol officers to make arrests was defined by the subsequent act of February 27, 1925 (43 Stat. 1049). This service was made necessary by the marked increase in recent years of aliens surreptitiously entering the United States, particularly along the Canadian and Mexican borders, due to the limitation on the number of aliens permitted to enter the United States by the Quota Act of May 19, 1921, as amended May 11, 1922, as well as by the further reduction of the number of admissible aliens by the Immigration Act of 1924. The extensive land border of the United States on the Mexican and Canadian sides, as well as our proximity to the islands of the West Indies and Cuba, make the work of preventing the illegal entry of aliens into this country one of enormous difficulty. The figures submitted by the Border Patrol Service indicate that this manner of unlawful entry into the United States is being brought under control and has the hearty coöperation of Canadian and Mexican officials.

Proposed Deportation Bill.—As a further means of preventing the illegal entry of aliens into this country a drastic deportation act was introduced and considered by the 68th Congress. This bill passed the House but failed to pass the Senate. One of the important features of this deportation bill was the removal of the limitation of time in which an alien might be deported from the United States for causes divided into fourteen classes. In this bill an effort was also made to control the entry of seamen into the United States, large numbers of whom enter and remain in the United States in violation of law. The deportation bill provided for the manner of deportation of such seamen as had remained in this country unlawfully, though the bill carefully protected the rights of legitimate seamen engaged in commerce.

Registry.—As a concomitant measure of protection to the United States from the entry of undesirable aliens it has been proposed that all aliens in this country be enrolled or registered. By this procedure it is thought that the naturalization of desirable aliens as citizens of the United States will be encouraged and the presence here of groups of undesirables more easily noted and controlled. It is possible that this subject may receive serious consideration by the present Congress in view of the fact that by a recent court decision of the Circuit Court of Appeals of the Eighth Circuit the penal provisions of the passport act of May 22, 1918, have been declared to be unenforcible (in re Stefan Flora).

Chinese Immigration.—Chinese of the laboring class are not entitled to enter the United States under the terms of the Chinese Treaty of 1880 and later acts of Congress. The records of the Immigration Service indicate that 1,721 alien Chinese were admitted to the United States during the fiscal year 1925, and 688 were denied admission, as against 4,670 admitted and 1,051 excluded in 1924. This decrease, in a measure, is due to the Immigration Act of 1924 which tends to reduce the number of Chinese entitled to enter this country. It should be understood that the bulk of alien Chinese entering this country are of the merchant and student classes. In the recent case of Chang Chan et al. v. Nagle, 268 U. S. 346, decided May 25, 1925, the Supreme Court of the United States decided that native Chinese women, being themselves ineligible to citizenship, do not become citizens of the United States by reason of marriage to American citizens and are not entitled to admission to the United States under the 1924 immigration act. Under our laws, however, the children of such union are American citizens. On the other hand, by the decision of the same court, on the same day, in the case of Cheung Sum Shee et al. v. Nagle, 268 U. S. 336, it was held that alien Chinese wives and minor children of Chinese merchants lawfully domiciled in the United States are not excluded by the 1924 immigration act, being guaranteed the right of entry into this country by the treaty with China of 1880.

The incentive for alien Chinese to gain admission to the United States is very great and the Immigration Service is constantly confronted with attempts to fraudulently circumvent the law. On the whole the entrance of Chinese into this country is well under control. The immigration records show that 19,710 seamen of all nationalities deserted their vessels in United States ports during the year 1925 and about 77,917 for the past three years. However, only a small percentage of deserting seamen were Chinese, in 1925 the number being 387. For the past five years the number of alien Chinese departing from the United States exceeded in number those entering, in 1925 there being 3,263 emigrant alien Chinese as against 1,721 immigrants.

Japanese Immigration.—Ever since 1903 the immigration of Japanese into the United States had been controlled by the plan called the "Gentlemen's Agreement" which provided in effect that Japanese of the laboring class would not receive the necessary passports for coming to the United States. This allowed, as in the case of Chinese immigration, Japanese lawfully to enter the United States for a considerable period as merchants, students and government officials. In 1925, 682 immigrant Japanese were admitted to this country and 1,170 emigrated, as against 8,481 admitted and 2,120 emigrated in 1924. The territory of Hawaii has a considerable alien Japanese population, but the entry of such aliens into the mainland of the United States is prevented by the Immigration Act of 1917 and Presidential proclamations thereunder.

Japanese immigration has been seriously affected as a result of recent decisions by the Supreme Court of the United States to the effect that under our laws Japanese are of a race ineligible to citizenship (Takoa Ozawa v. United States, 260 U. S. 178, and Hidemitsu Toyota v. United States, 268 U. S. 402), also by the announced intention of Congress in passing the 1924 Immigration Act to officially end the operation of the so-called "Gentlemen's Agreement" with Japan. The treaty of April 5, 1911, with Japan provides for the entrance of Japanese into the United States to carry on trade, and in the recent case of Asakura v. City of Seattle, 265 U. S. 332, the Supreme Court of the United States decided that a law of the State of Washington which licensed and recognized pawnbroking as a business regulates "trade" within the meaning of the Japanese treaty; and that a city ordinance in that state which undertook to confine the business to citizens of the United States was void as applied to a Japanese subject who was lawfully domiciled in the United States. Of the 19,710 seamen who deserted their vessels at ports of the United States in 1925 but 64 were Japanese.

Mexican Immigration.—Because of the fact that there is no quota limitation applying against aliens born in British North America and Mexico, as well as Cuba, Haiti, the Dominican Republic, and independent Central and South American countries, the immigration to the United States from the two border countries of Canada and Mexico has been extremely high, in comparison with that from European countries, for example. In 1914 immigrant aliens from British North America numbered 86,139, as against 14,614 from Mexico. In 1923 the number admitted from British North America was 117,011 and 63,768 from Mexico. In 1924, 200,690 were admitted from British North America and 89,336 from Mexico, while for the year 1925 there were admitted 102,753 from British North America and 32,964 from Mexico. It is possible that the decrease in 1925 from the number admitted in 1924 may be due to the fact that, besides the head tax of $8 required by the 1917 Act, the 1924 Immigration Act exacts a consular tax of $10 for an immigration visa. In any event it is believed that this factor has tended to increase attempts to smuggle aliens into the United States across the border. The more settled political conditions in Mexico in recent years have been a factor in reducing emigration from Mexico, as well as the fact that the Mexican Government now discourages the emigration of its citizens. Senate Bill 2365 was introduced in the 68th Congress to extend the quota limitation to the immigration from independent countries of the Western Hemisphere and to regulate the admission of seasonal and special labor from contiguous territory. This bill failed to pass Congress.

Alien Registration.—Following the adoption of our restrictive immigration policy there has been a great increase in the number of surreptitious entries of aliens across our borders and by sea. The practice of smuggling aliens in particular has increased, and there are well-organized groups or bands along our land borders who have been engaged in this practice, for which they have often received very large sums of money as rewards for conducting their illegal operations. For the purpose of reducing such illegal entries to the lowest practical minimum and, subsequently, to frustrate the fraudulent efforts to become citizens on the part of those who have entered the country in violation of our immigration laws, Secretary Davis has formulated, and is urging the enactment of, legislation that will provide for a system of annual registration and enrollment of all aliens.

The purpose of such registration would be to promptly ascertain the presence of aliens arriving in the country unlawfully and to expedite their deportation, and also for the protection of aliens who may be in the country lawfully. President Coolidge in his first annual message to Congress recommended the adoption of the registration system. The plan is not conceived in a spirit of resentfulness or prejudice against aliens, nor has it any of those features of espionage which characterize the administrative system of continental Europe which are so dreaded by the people who have come to us from the countries where such a system prevails. France requires foreigners to register who remain in the country more than fifteen days. European people generally have been accustomed to registering every time they change their abode. The registration system proposed is free from the annoying features of the continental system and would devolve upon the alien no greater inconvenience than does the law which requires citizens to register every year or two in order to qualify themselves as legal voters. It would also greatly simplify and facilitate the legal procedure of their naturalization.

Aid to Registration Advantageous to Aliens.—The persistent, subtle efforts, both by sea and land, of vast numbers of aliens who are constantly seeking to enter the United States by evading the immigration laws must be met with unremitting vigilance and unyielding firmness in order to thwart their unlawful attempts and to maintain the integrity and the effectiveness of our immigration policy. Among the essential features of this proposed plan is the protection afforded by the certificate of registration to those aliens who comply with our immigration laws, which in their enforcement can only be obnoxious to those who seek to subvert them. It is in no sense prejudicial to any race or inimical to the rights or liberties of any class of people. If effectively administered, it would be very efficient in enabling us to discover the presence of aliens unlawfully in the country, particularly those of a vicious and menacing type who enter for the purpose of disseminating communistic and anarchistic doctrines, but would also deter others from attempting illegal entry because of the reasonable certainty of prompt discovery and deportation upon arrival.

The adoption of the proposed system of registration and enrollment would be no reflection upon the aliens, and compliance with its provisions would involve no humiliation, and at the same time it would greatly safeguard from persistent and insidious assaults one of the most vital and protective pieces of legislation enacted by our country in the last half century.

RELATION OF IMMIGRATION TO CITIZENSHIP

By Raymond F. Crist
Commissioner of Naturalization, Department of Labor

The Constitution of the United States empowered the Congress "to establish a uniform rule of naturalization." The Act of June 29, 1906 (34 Stat. L. Part I, page 596), constitutes the most important expression of the Congress under this authority. The Bureau of Naturalization of the United States Department of Labor is the executive unit charged with the administration of this law, to insure the uniformity of rule throughout the United States required by the Constitution.

Dwelling in the U. S.—By this law an alien may declare his intention to become a citizen of the United States in the court in whose jurisdiction such alien resides. The Supreme Court of the United States, on March 2, 1925, held that until an alien is legally landed he "could not have dwelt within the United States" and "never has been dwelling in the United States within the meaning of the Act." This was the case of a minor child claiming naturalization through her father, although she had not been formally admitted to reside within the United States in conformity with the immigration laws. The Supreme Court further said "still more clearly she never has begun to reside permanently in the United States within the later Act of March 2, 1907." The Supreme Court cited the case of The United States ex rel. Patton v. Tod (259 Fed. 385). In that opinion, the United States Circuit Court of Appeals said, "When the Act of 1802 became law, there was no immigration statute. Since then legislation in respect of immigration has become necessary, and we must look to the immigration statutes to ascertain when an alien can be regarded as beginning his residence in this country."

Petition for Naturalization.—The Naturalization Act of 1906 as amended constitutes the present-day naturalization law, with other statutes which relate to the acquisition of citizenship of children born abroad and living either abroad or in the United States at the time of the naturalization of their parents. An alien is not allowed to declare his intention excepting in the Court in whose jurisdiction he resides. The first step is the petition to the Court, which cannot be filed until five years of residence have been completed and the declaration of intention is at least two years old and after a year of residence in the state. If an alien waits until his declaration is seven years old it becomes invalid. Two citizens of the United States must prove all of the residence within the state in which he resides at the time of petitioning that is necessary to make five years, but any portion of that time that has been in some other state may be proven by other citizens.

Eligibles.—The petition must be signed by the alien in his own handwriting, but he cannot be admitted to citizenship unless he can speak the English language, and not then if he is a believer in the practice of polygamy or anarchistic doctrines, or is one who practices either. At the time the petition is filed he must surrender his declaration of intention to the Clerk of the Court along with a certificate showing the time, place and manner of his arrival in the United States. This certificate is furnished by the Department of Labor and is required in all cases of arrival after June 29, 1906, unless the alien is in the military or naval service of the United States, or the American merchant marine after an honorable discharge from a prior service.

Forms.—The petition is not allowed to be heard until notice of its filing has been publicly posted for at least ninety days. The law requires regular days to be fixed by rule of Court for hearing petitions for naturalization.

No declaration of intention may be made and no petition for naturalization may be heard within thirty days preceding any election.

Races.—Only aliens who are white persons or of African nativity or descent are entitled to naturalization. This excludes, under decisions of the Supreme Court of the United States, Japanese and Hindus, while the Chinese are excluded by statute enacted during the existence of the treaty with China relating to the admission of Chinese into the United States.

Fees and Penalties.—A fee of $1 is prescribed for a declaration of intention, and $4 for the filing of the petition, which includes the right to the certificate of naturalization if it is granted. One-half of these fees are required to be accounted for and paid over to the Bureau of Naturalization by the Clerks of Courts to whom they are paid. They are then deposited in the Treasury of the United States.

Penalties are provided for violating the naturalization law or for holding oneself to be a citizen before one is naturalized.

Privileges.—The citizenship conferred is limited to the continuance of permanent residence in the United States, and all privileges are extended to a naturalized citizen that are the right of a native citizen excepting the privilege of holding the office of President or Vice-President, or unlimited residence outside of the United States. While a native-born citizen may reside outside of the United States for any length of time he may desire without loss of citizenship, continued residence on the part of a naturalized citizen sets up the presumption that he has ceased to be a citizen of the United States, which presumption he must overcome before being recognized as a citizen.

Unnaturalized Aliens.—The naturalization problem of this country and its relationship to the alien population can only be reviewed with clarity upon the presentation of the mass problem. The most available statistical record is found in the census report of 1920. That report presents the entire alien born population as 13,920,692. This includes men, women and children of foreign birth in this country at that time.

There were 5,398,605 unnaturalized foreigners, and 1,223,490 foreigners who had taken out their first papers only, the declaration of intention to become citizens of the United States. These two groups comprise a total of 6,622,095. In addition to these there were 805,509 of foreign birth as to whom it was impossible to ascertain whether or not they had changed their allegiance. With these added to the number known not to have changed their allegiance, the total foreign born not identified as citizens, is brought up to 7,427,604. In the entire mass of alien born there were

6,493,088, or less than one-half, who had acquired American citizenship by naturalization.

Since 1920 there were accessions to the foreign group through all immigration ports of entry, while at the same time there was an outgoing number, but a clearly defined and computable net result of this ebb and flow of human tide shows an increase of 2,007,575 to the foreign population. This included the 232,945 which were added during the last year.

Transaction.—The importance of the question of naturalization of aliens in the United States outranks the naturalization of aliens in any other country of the world, if not more important and having greater possibilities for reaction upon the future of this country than the consequences that flow from the naturalization of aliens upon all other countries combined.

Since 1906, when supervision through the Federal Bureau was established, 2,040,500 certificates of naturalization have been granted. This included the 152,457 naturalized during the year 1925. This represents probably one-half of those actually naturalized for the reason that an average of more than one person has uniformly derived citizenship through the naturalization of the petitioner, as shown by various studies made of naturalization petitions.

From the alien population coming into the United States since 1920 only those who arrived in the year 1920 could by any possible provision of the law have acquired citizenship until during the last year, excepting the small and negligible number who acquired citizenship through military service or service in the American merchant marine for three years, and those who derived citizenship through the naturalization of another.

The number of aliens taking the various steps toward citizenship represented 591,933 in the year, and these, together with the persons interested in questions relating to the naturalization law and the rights and privileges accruing upon the acquisition of citizenship, entailed the receipt of 1,056,875 pieces of mail and the sending out of 1,243,801 pieces of mail. Much of this mail is centered on the administrative headquarters in Washington, whose incoming correspondence averages 590 pieces of mail daily.

Men and Women.—There were 277,218 declarations of intention received from aliens during this year. Heretofore and prior to the enactment by Congress of the Act of September 22, 1922, there were as a rule a negligible number of declarations of intention filed by women. This Act gave the right of independent naturalization to women and freed the question of allegiance and citizenship from the influence of the marital status. Under the influence of this Act the number of declarations from women of foreign birth has increased steadily each year, and amounted to 51,527 during the present year. There were 225,291 declarations of intention received from men out of the total. The number of women petitioning for citizenship was 22,526, and those filed by men 139,732, comprising a total of 162,258. Citizenship was conferred upon 18,576 women and 133,881 men, making a total of 152,457 adults who were made citizens during the past year, with 15,613 aliens refused citizenship. In the large number of petitions filed there has been always a small percentage of disclosures of attempts to secure naturalization illegally. There were 151 cases of individuals prosecuted criminally during the year and 62 convictions, 13 failures to convict and 76 cases still pending. From those convicted there were $10,860.80 fines, penalties and forfeitures to the United States.

Judicial Decisions.—The most important of the suits to terminate citizenship was the one decided by the Supreme Court of the United States in May. By this decision the Supreme Court held that only part of the soldiers, sailors and marines who had served in the military forces of the United States during the World War had been provided by Congress with the means of acquiring citizenship when the subject was considered in the law passed May 9, 1918.

Preliminary Examinations. — The stupendous character of the administrative responsibilities is shown by the fact that 1,185,896 individual examinations of aliens and their witnesses were made necessary in the administration of the naturalization law during the year. These examinations comprise 486,774 administrative examinations of petitioners and their witnesses prior to the court hearings, and 699,122 judicial examinations by the naturalization examiners in open court. This work was performed by a personnel of 300 men and women performing duty in offices located in twenty-eight centers, from which places they travel over the adjoining territory performing the duties necessary to the proper enforcement of this law.

Cost of the Service.—The administration of the naturalization law is no expense upon the citizen tax payers of this country. The total cost of the administration of the naturalization law has been $8,840,154.39. The government requires the deposit in the Treasury of the United States of the greater portion of the naturalization fees which the law prescribes shall be paid by aliens. The total naturalization and other fees deposited through the naturalization law up to and including 1925 amounted to $9,189,277.73. The total cost of the administration of the law was $8,840,154.39, leaving a surplus of $349,128.34 over all costs. The total income during the past year was $743,836.54, while the expense was $786,852.11. As the surplus now stands, the expenses are paid by revenues nearly six months in advance of the total expenditures.

Advantages to Immigrants.—The certificates of naturalization are made use of by naturalized citizens who desire to obtain preference and exemptions from the immigration visa requirements for the various members of their families remaining outside of the United States who are entitled thereto. These naturalized citizens file petitions for immigration visas, all of which are visaed and approved by the Bureau of Naturalization before the petition is granted. There were 22,617 such petitions received in the Bureau of Naturalization during the past year. Of these there were 1,500 petitioners who had so recently been naturalized that their certificates of naturalization had not been received in the bureau for filing from the Clerks of Courts.

Use of Immigration Visas.—The Bureau of Naturalization is the custodian of all immigration visas surrendered by immigrants under the 1924 Immigration Act at the various ports of entry throughout the United States. There were 276,815 immigration visas received and filed in the bureau during the past year.

These visas were examined to prove the claims of lawful entry of 25,818 aliens who applied within the first year after their arrival in the United States for the privilege of becoming citizens. Among these, refusals resulted in 1,420 cases where the admissions were not as immigrants but for visits of temporary character, and 3,629 whose entry was indicated to have been lawlessly accomplished. A disclosure of significance is seen in the cases of 5,963 aliens who gave occupations entirely different from those which were shown upon their immigration visas, when it is known that preferences are given to certain aliens because of the vocations claimed before the Consuls. This activity also discloses aliens illegally here who are scattered throughout the United States away from the large alien colonies of the industrial cities. Fraudulent naturalization will, therefore, be attempted at places where, heretofore, only law-abiding aliens have been found. There were 111,209 quota-period aliens who applied during the year to establish residence and take out the first papers.

Certificates of Arrival.—During the year there were 125,000 applications for certificates of arrival for petitioning purposes received at the Ellis Island branch of the Bureau of Naturalization. These certificates, with those issued from the Immigration Service elsewhere, comprise the total of approximately 162,000 petitions for naturalization filed during the year.

Districts.—Heretofore the Naturalization Service has been administered through eleven districts and fourteen subdistricts, comprising the whole

United States. During the year the administrative machinery was made more compact by increasing the number to twenty-three districts in four of which sub-headquarters were located. This made all but four of the branch offices immediately under the direction of the bureau in Washington.

The Citizenship Training Work of the Bureau of Naturalization.—This was specifically authorized by the Act of May 9, 1918, and has been promotive of the opening of the public schools throughout the United States for the instruction of adult immigrants. During the year there were 79,964 textbooks furnished to the students attending these classes who were candidates for citizenship.

Recommendations for amending the naturalization law.—Recommendations for amendment of the law were made during the year, based upon the nineteen years of administrative experience, and also upon the latest legislative expressions in the immigration laws. Among the more important of these recommendations is the enrollment or registration of all aliens annually, with the payment of a fee for the certificate of registration and the more effective organization therefrom of the public school system in the teaching of adult immigrants. The natural consequence would be the requirement to read, speak and write our language.

Proposed Administrative Naturalization.—It has been recommended that the naturalization of aliens cease as a primarily judicial function and be vested with the administrative branch of the Government, with the right of appeal to the appropriate United States Courts on questions of law and after questions of fact have been reviewed by the Bureau of Naturalization in Washington in any case. This would change the traditions of the country from the first enactment of Congress which made naturalization a judicial function. Since that time the naturalization of aliens has grown to such proportions as to make it necessary for the Courts to depend almost entirely upon the Naturalization Examiners representing the administrative branch of the Government at the judicial proceedings. The public naturalization is hence a purely perfunctory proceeding generally, lacking in dignity and occasioning a great deal of criticism on the part of the public. Inasmuch as the responsibility is largely administrative and a considerable portion of the judicial responsibility is by reason of circumstances further imposed upon the administrative branch, those experienced in the naturalization law, in the large centers particularly, including Federal and State Judges, are advocates of the change.

Photographs.—Photographs are recommended for attachment upon all naturalization papers at the time of their issuance for identification, prevention of their fraudulent use, and protection of the naturalized citizens.

The requirement of proof of lawful arrival.—This and the refusal of the privileges of naturalization to aliens unlawfully in the United States, with a discretionary authority vested in the Bureau for the relief of those who entered prior to the quota restrictions, are recommended.

Other Recommendations.—Among the other recommendations are a fee for certificate of arrival as evidence of lawful entry, increase above the present fees of $1 for the declaration of intention and $4 for the petition for naturalization which includes the issuance of the certificate of naturalization; the vesting of power in the Naturalization Service to make findings of which the Courts could take judicial notice at the hearing, and dispensing with the appearance of the two witnesses in Court at the hearing; permission to file a petition for naturalization in any authorized Court without awaiting the completion of one year of residence in the State, Territory or District of Columbia, all other residence to be established by depositions; the personal appearance of each applicant before a Naturalization Examiner prior to the filing of his petition for naturalization; that the children of those naturalized should appear in open Court upon arriving at adult age and before exercising the rights of citizenship as adults take the oath of allegiance and secure their own certificates.

STATISTICS OF IMMIGRATION

By Arthur E. Cook

Assistant to the Secretary of Labor

ALIENS ADMITTED TO THE UNITED STATES UNDER THE IMMIGRATION ACT OF 1924, DURING THE FISCAL YEAR 1925

By Country or Area of Birth, as Specified.

(Quota immigrant aliens are charged to the quota; nonimmigrant and nonquota immigrant aliens are not charged to the quota. Hence the total immigrants may exceed the total statutory quota.)

Country or Area of Birth	Admitted			Total Admitted Fiscal Year 1925
	Quota Immigrants	Annual Quota	Non-immigrant and Nonquota Immigrants	
All countries	145,971	164,667	301,115	457,086 *

LEISERSON, William N.—*Adjusting Immigrant and Industry*. Harper & Bros., 1924. A study of the experiences of immigrants and industries and the methods of adjustment that have proved most successful and beneficial.

ROBERTS, Kenneth L.—*Why Europe Leaves Home*. Bobbs-Merrill Co., 1922. An account of the reasons which cause Central Europeans to overrun America, which lead Russians to rush to Constantinople, which coax Greek royalty and commoners into strange by-ways and hedges and which induce Englishmen and Scotchmen to go out at night.

SADLER, William S.—*Race Decadence*. A. C. McClurg Co., 1922. An examination into the causes of racial degeneracy here in the United States.

TREVOR, John Bond.—*An Analysis of the American Immigration Act of 1924.* Carnegie Endowment for International Peace, 1924.

TROTTER, William.—*Instincts of the Herd in Peace and War.* Macmillan, 1920.

JOSEY, Charles Conant.—*Race and National Solidarity.* Scribners, 1923. An inquiry into the validity of much of our current social idealism, "calling attention" to the value of a strong group consciousness.

DIVISION XXVI
LABOR AND LABOR LEGISLATION

CONDITIONS OF LABOR

By George Soule
Editorial Department, New Republic

Tendencies. — Detailed information on various aspects of conditions of labor during the year will be found in the other sections of this Division. In general, it may be said that it was a year of comparatively little conflict, that wages and the purchasing power of wages showed small change during the year and remained, for factory workers, transportation workers, and the building trades, somewhat above the pre-war level. Standard hours of work showed little change. The volume of employment in the building trades was high, in the manufacturing industries was fair, though below the peaks of both 1920 and 1923. In transportation it showed a diminution from immediately preceding years, and in bituminous coal mining was very low until the anthracite strike diverted more demand to the soft coal fields.

Difficulties.—The chief trouble spots were in textiles and coal mining. A wage reduction movement, particularly in woolens, evidenced principally in New England, was noted during the first few months of the year. Slack output and employment in bituminous coal led to reductions of wages to the 1919 and even in many cases to the 1917 scale in the non-union districts and even in some of the union mines.

The housing shortage, which had been particularly severe for labor ever since the war, was but little alleviated by the building boom except for the highest paid groups. Toward the end of the year a formidable agitation for the use of public credit in building adequate low-cost housing was begun in New York.

Labor Enterprises.—The chief advances made by labor during the year were in new kinds of endeavors begun after the war. Thirty-one labor banks had been established, showing resources of over $100,000,000, deposits of over $86,000,000, surplus and profits of over $2,750,000, and capital of over $8,000,000. A few labor investment companies were active. Workers' education made progress, both through the activities of the Workers' Education Bureau, affiliated with the A. F. of L., and resident labor colleges such as Brookwood. The movement for union-management coöperation for better service on the basis of a fair sharing of benefits achieved was strengthened on the Baltimore and Ohio Railroad, where it began, and was extended to other systems such as the Canadian National. The adoption by the A. F. of L. of a new wage principle based on productivity is recorded under Labor Organizations. President Green of the A. F. of L. addressed the Taylor Society and the Management Division of the American Society of Mechanical Engineers offering coöperation by trade unions and was received with cordiality.

XXVI. LABOR AND LABOR LEGISLATION

LABOR ORGANIZATIONS

By George Soule
Editorial Department, New Republic

The American Federation of Labor, meeting for its forty-fifth annual convention in Atlantic City, N. J., Oct. 5, reported a paid-up membership of 2,887,297 in affiliated unions. This is an increase of 12,318 over the previous year, and the first gain since 1920, when the membership began to decline from the peak of 4,078,740. It constitutes a rise of 887,000 or 44 per cent. from the pre-war level of about 2,000,000 existing in 1913-14. Such an increase is about in line with the normal trend of growth from 1900 to 1914. Forty-nine state federations, 107 national and international unions, 850 city central bodies, and 31,261 local unions were reported. Unions reporting increased membership included the building trades, barbers, railway clerks, fire fighters, stationary firemen, fur workers, longshoremen, musicians, post office clerks, street railway employees, teamsters and printing trades.

William Green, formerly Secretary of the United Mine Workers of America, and elected President of the Federation by the Executive Council after Samuel Gompers' death in 1924, was elected to succeed himself by the Convention without opposition. James P. Noonan, President of the International Brotherhood of Electrical Workers, was elected by the Convention to succeed himself as Eighth Vice-President of the Federation, to which position he had been appointed by the Executive Council to fill the vacancy caused by the succession of Mr. Green to the Presidency. All other officers were the same as the previous year.

Proposals of the Federation.—The Convention adopted numerous resolutions in favor of an organizing campaign and assistance in organizing special trades and localities. Special attention was given to the organization of women, of the city of Detroit, of North Carolina, of clerical employees and of machinists in garages and automobile repair shops. It also adopted a resolution on wages, opposing wage reductions, urging "elimination of wastes in production in order that selling prices may be lower and wages higher," and enunciating the principle that real wages should be increased and hours of work reduced "in proportion to man's increasing power of production." Other important resolutions upheld the Child Labor Amendment to the Constitution, opposed the formation of a labor party and reaffirmed the nonpartisan political policy, supported the Workers' Education Bureau, etc.

Other Organizations Not Affiliated with the A. F. of L. have a membership of about 680,000. Of these the most important, numerically and industrially, are the four train-service railroad brotherhoods, the Engineers, Firemen, Conductors and Trainmen, with about 425,000 and the Amalgamated Clothing Workers of America with about 135,000. Warren S. Stone, President of the Brotherhood of Locomotive Engineers and a leader prominent in all activities of labor, died June 12, and in his place was elected William B. Prenter. The Conductors held their convention May 4 in Minneapolis, the Trainmen May 12 in Cleveland and the Firemen June 1 in Detroit. Action taken concerned chiefly routine matters. The Amalgamated Clothing Workers made a significant gain in December when the clothing factory of A. Nash & Co., Inc., in Cincinnati was organized without a strike. The owner of the establishment, Arthur Nash, popularly known as "Golden Rule Nash" because of his announced intention to apply Christian principles in his business, had long been pointed out as an employer who operated a factory under good labor conditions without a union shop, but he came to the conclusion that his employees should be allowed to organize and affiliate with the national union and that he should deal with them through union collective bargaining. During the year a vigorous attempt was made to form a union of Pullman porters.

INTERNATIONAL RELATIONS OF LABOR

By George Soule

Editorial Department, New Republic

Affiliations.—The American Federation of Labor decided upon efforts to increase affiliations with the Pan-American Federation of Labor and to assist the organization of trade unions in Spanish-American countries. As an aid to international comity, it recommended representation of the A. F. of L. in the activities of the Pan-American Union, the Pan-American Financial Congress and the recently created Arbitration Board.

The A. F. of L. convention was addressed by fraternal or visiting delegates from the British, Irish, German, Canadian and Mexican labor movements.

The President of the A. F. of L. was instructed by the Convention to continue negotiations with the International Federation of Trade Unions (the Amsterdam International) to find a basis for reaffiliation by the A. F. of L., which had withdrawn during the war.

Holding Off.—On December 23 President Green of the A. F. of L., on the authority of the Executive Council, addressed a letter to the members of the American Labor movement denouncing Italian Fascism, saying that it was as great a menace to liberalism, international peace and trade-unionism as was Russian Communism, and warning Italian workers in this country against the Fascist movement.

The A. F. of L. refused to have anything to do with the effort recommended by A. A. Purcell, fraternal delegate of the British Trades Union Congress, to bring about fraternal relations with the Russian trade unions or the "Red" international. It voted down a resolution in favor of recognition of the Soviet government by the United States.

Seamen.—The A. F. of L. protested against the adoption of a proposed international seamen's code prepared by the Labor Office of the League of Nations, on the ground that it would perpetuate involuntary servitude on board ship by penalizing seamen for quitting work in harbor. It vigorously disapproved proposed methods for the registering of aliens in the United States.

Mexico.—President Green in June inquired of the Secretary of State concerning the purpose and basis of his public declaration on the affairs of Mexico, and the Federation later approved Mr. Green's action and declared itself a champion of the rights of the Mexican people. It endorsed the creation of a joint commission by the A. F. of L. and the Mexican Federation of Labor for the study of immigration and emigration and the voluntary regulation of migration of workers between the two countries. It opposed extension of the quota provisions of the immigration law to Canada and Mexico.

The A. F. of L. raised the funds to furnish a room in the International Labor Office of the League of Nations.

Extraterritoriality. — Consequent upon the strike in China directed against foreign interests, President Green of the A. F. of L. wrote a letter, July 10, to President Coolidge declaring for the abolition of extraterritorial rights in China. The October convention endorsed his action and passed a resolution favoring "the withdrawal from all nations of extraterritorial privileges" and "giving to China customs autonomy." It also extended to the Chinese Federation of Labor an offer of "all possible assistance in the development of their trade union movement," and expressed concern for the establishment of high labor standards in all countries bordering the Pacific. It reaffirmed its position, however, in favor of exclusion of Asiatic labor from the United States, whether Chinese or Japanese.

World Court.—The Executive Council was directed to study the World Court proposal and report its findings. It was also directed to aid the movement for international disarmament.

XXVI. LABOR AND LABOR LEGISLATION

LABOR IN POLITICS

By George Soule

Editorial Department, New Republic

Proposed Labor Party.—The year was not one of important elections and the chief activity of labor in politics was the aftermath of the La Follette campaign of 1924 and preparations for the future. The Cleveland convention which nominated Robert M. La Follette for the Presidency resolved that a convention should be held in February, 1925, to consider the organization of a permanent party. After the November elections, a number of the railroad labor organizations which had been among the most important union supporters of the independent movement attempted to prevent the calling of this convention, but were over-ruled by the political executive officials created before the election. The convention was held Feb. 21 in Chicago.

The railroad labor delegates at once announced that their organizations would not officially take part in the deliberations, though they could not prevent officers or members of the unions from doing so as individuals. This action forced the convention to depart from any plan of continuing the party as a coalition of groups. The Socialists announced that they could not take part in the movement except as an autonomous group, and their support for the movement was therefore withdrawn when it was decided not to continue it nationally on a group basis. The final action looked toward the formation of a party on a basis of individual affiliation, but allowed certain autonomy to state units in making group affiliations with the consent of the national executive committee. Since this convention, the only visible activity in the movement has been on the part of several state organizations.

Socialists.—After the death of Robert M. La Follette a special election was held in Wisconsin to fill his place in the Senate. Robert M. La Follette, Jr., was nominated in the Republican primaries by a majority of over 160,000 over his 3 rivals, and was elected by a majority of about 113,000, the Socialist candidate, John M. Work, receiving about 11,000 votes. The only other important election of the year in which the Socialists took part was the municipal election in New York City, in which Norman Thomas, the Socialist candidate for Mayor, received 39,000 votes, as against 82,000 for the Socialist candidate in 1921 and 145,000 for Morris Hillquit in 1917.

Attitude of American Federation of Labor.—At its October convention in Atlantic City the Federation voted almost unanimously to continue its non-partisan political policy. The report of the Executive Council on this matter contained the following passages: "During the years since the non-partisan political policy has been followed by the American Federation of Labor it has seen many independent or third party movements come and go. . . . The Executive Council believes that as a result of its non-partisan political policy the launching of third party movements has been proved wasted effort and injurious to the desire to elect candidates with favorable records. The 1922 and 1924 political campaigns definitely determined this fact." The committee in charge later reported to the convention that in the last election the Federation endorsed 303 candidates for the House of Representatives, of whom 186 were elected. Of those indorsed 280 were Republicans or Democrats and 23 were independents or nominees of minor parties. A resolution favoring the formation of a Labor Party was overwhelmingly defeated. In response to a question from a delegate as to whether the position of the Federation would prevent it from indorsing labor party candidates in localities where these candidates were satisfactory to the Federation and had a good chance of election as in the case of Senators Shipstead and Johnson in Minnesota, President Green answered in the negative.

Relation to Political Methods.—The convention resolved to safeguard the direct primary and facilitate any means for enabling voters to split their tickets or to vote for independent candidates. It resolved to accept the coöperation of sympathetic individuals outside the labor movement in carrying on its campaign. It resolved to prepare actively for the Congressional elections of 1926. It resolved to oppose the attempt to establish more drastic rules for cloture of debate in the Senate. In discussion of this measure President Andrew Furuseth of the Seamen stated that when some years ago there had been determined agitation for a labor party, an investigation had been undertaken of the cloture rules of the House, which showed that because of them no minority could even procure consideration of a measure opposed by the majority without sufficient votes to command a roll call, and that labor had no hope of electing directly enough members to demand a roll call. The cloture move which occurred in the Senate was considered part of an attempt to reduce minorities to a similar impotence in that body.

The Workers Party.—The non-secret political branch of the Communist movement in the United States made no progress during the year. The activities of the Communists in the trade-unions suffered numerous set-backs, and the struggle within the Communist organization between the two factions led respectively by W. Z. Foster and C. E. Ruthenberg became more embittered and resulted in numerous complications which cannot be authoritatively discussed because of the policy of secrecy maintained by the organization. (See article on Bolshevism in this volume.)

STRIKES AND LOCKOUTS

By George Soule

Editorial Department, New Republic

IN GENERAL

Number of Strikes.—Strikes and lockouts were in general less numerous and less severe than for any year in the preceding decade, with the exception of 1922. The record of the United States Bureau of Labor Statistics for the first 6 months shows 274 strikes in the first quarter and 446 in the second quarter, as compared with 310 and 430 respectively in 1924. Employees involved, so far as reported, numbered 101,179 in the first quarter and 98,377 in the second. Only 14 strikes were reported in the first quarter involving 1,000 or more employees, and the total of employees in these strikes was 72,160. In the second quarter 23 strikes involved 1,000 or more and included in all 61,430 employees. But one employer was involved in each of 208 strikes in the first quarter, two to five employers in 13 strikes, more than five employers in 12, the figures not being reported for 41 strikes. In the second quarter the corresponding figures were: one employer—264 strikes; two to five employers—35 strikes; more than five employers, 41 strikes; not reported, 106. The average duration of strikes was 15 days in the first quarter and 22 days in the second, total days lost being 4,138 and 5,330 respectively.

Causes.—As usual, a large proportion of strikes involved wages either directly or indirectly, the number being 103 in the first quarter and 219 in the second. Other prominent causes were, unfair products, general conditions and recognition of the union. In the first quarter, 187 strikes were by union members, 30 by non-union, 11 by both, and 42 were not reported. In the second quarter, 365 were by union members, 35 by non-union, 9 by both, and 31 were not reported. In a considerable number of cases the strikers were unionized during the course of the dispute.

Results.—The employees came out of the strikes with greater advantage than the employers. Employers won 57 strikes in the first quarter and 56 in the second, as against victory for employees in 61 cases in the first and 117 in the second quarter. In addition many gains for employees were made in the strikes compromised, numbering 29 in the first quarter and 65 in the second, and in those arbitrated, numbering 17 in the first quarter and 10 in the second. Results of 73 strikes were not reported.

Distribution.—A large number of the strikes were confined to a comparatively few industries and occupations. In the first quarter, 62 were of clothing workers, 54 of textile, 40 of building, and 26 of coal miners. In the second quarter, 178 were of building workers, 58 of clothing workers, and 27 each of bakers, miners and textile workers. New York, Pennsylvania and Massachusetts led in the number of strikes in both quarters. Similar figures for the last half of the year are not available, but they would probably show no greater number or severity of strikes, but rather less, with the single exception of the anthracite coal strike. There was almost certainly a falling off of strikes in textiles and building trades.

ANTHRACITE COAL STRIKE

Occasion.—The most important strike was that of the 58,000 anthracite coal miners, beginning Sept. 1, the date of expiration of the previous agreement. The union requested a 10 per cent. wage increase for miners and $1.00 per day more for miners' laborers, the check-off of union dues and assessments, and changes in working conditions. At the beginning of joint negotiations the operators' committee requested the union to agree to arbitrate all disputes remaining unsettled on Sept. 1, and to remain at work pending a final settlement. This request the union refused, citing their fixed opposition to arbitration as a result of their experience with it in 1920, which they held demonstrated the unsuitability of delegating important questions to the decision of those outside the industry. During the negotiations the union presented its demands and the reasons for them first; the operators declined to make any important concessions and withheld their answers to the union's arguments until the latter should be all on record. President Lewis of the United Mine Workers of America charged that the operators' committee was without power to make concessions and was not engaging in genuine bargaining, and as a result broke off negotiations. The strike began on September 1 and was completely effective, all workers leaving the mines except those necessary to prevent their flooding. Prices of anthracite rose markedly and before long a serious shortage was in evidence. Local authorities urged the substitution of soft coal, coke or oil, and such substitutions were largely made, although the prices of soft coal and coke also rose considerably.

Governor Pinchot's Plan.—Numerous unsuccessful private attempts at mediation were made during the strike. Governor Gifford Pinchot of Pennsylvania called representatives of the union and the operators to a public meeting on November 28. The union representatives attended, but the operators remained away on the ground that any proposal should have been communicated to them privately before being made public. Mr. Pinchot presented a tentative plan of settlement on the basis of: a wage increase if it could reasonably be made without increasing the price of coal, otherwise no increase; a modified form of the check-off depending on the consent of the workers concerned in each case; an impartial board of seven to examine the accounts of the operators and settle the question of wages after a six months' investigation; work to be resumed on the signing of an agreement embodying the above conditions. The union immediately accepted the proposal as a basis of negotiations; the operators refused it, maintaining that it was unsound economically on account of the provision as to prices, and reiterated their original stand in favor of immediate resumption of work, unconditional arbitration, and provision against future stoppages.

Proposals.—A voluntary committee of 41 prominent economists and engineers addressed a letter to both sides stressing the importance of continuous operation and recommending that the industry remove the basic causes of strife by erecting a "continuing joint agency which will concern itself, not so much with the adjustment of grievances, as with the constructive consideration of the underlying economic and technical facts by which all questions of wages, working conditions and earnings must in the end be determined." It pointed out that a joint effort to improve methods of production and distribution can at the same time increase wages and reduce prices to the consumer. After several other unsuccessful attempts to bring the parties together, they finally agreed on Dec. 24 to resume negotiations without conditions.

AMALGAMATED CLOTHING STRIKE

A bitterly fought strike was that of the Amalgamated Clothing Workers against the International Tailoring Company and the J. L. Taylor Company, with plants in Illinois and New York, which began on July 1, and continued for 19 weeks. It was precipitated by the refusal of the employer to renew his agreement with the union and his announced intention to operate a non-union shop. Drastic injunctions were granted the employer by New York courts. The union was victorious, a new contract being signed and friendly relations reëstablished.

New York dressmakers affiliated with the International Ladies' Garment Workers' Union, numbering 30,000, struck on March 10 in 2,000 shops to enforce a provision of the agreement. The strike was novel in that the strikers reported at their places of work and sat at their machines without working. After six days success was attained. A strike of New York garment workers affiliated with the same union called on Feb. 17 for a wage increase, a 40-hour week and complete unionization, affected 850 shops and was ended by compromise after 20 days.

OTHER STRIKES

One of the longest strikes of the year was that of the 2,360 employees of the American Thread Company at Willimantic, Conn., affiliated with the United Textile Workers of America, against a 10 per cent. wage reduction. This was still in effect on Jan. 1, 1926. Its progress was marked by much hardship and bitterness, and the eviction of strikers from houses which were owned by the company.

A long strike was that of the locomotive engineers and firemen on the Virginian Railway, begun in 1923 as a consequence of the discharge of 12 employees for refusal to operate locomotives which they considered unsafe or dangerous to health, and still continuing in 1925. On Oct. 16 the locomotive engineers and firemen struck for the prevailing national wage increase on the Western Maryland. Though the Labor Board intervened, the strike was continued on account of a dispute about seniority in reemployment of the strikers. Telegraphers struck during the latter part of the year on the Atlantic Coast Line.

A strike of 2,500 municipal employees of Chicago, street sweepers and teamsters, for higher pay, beginning on February 11, was successful after 11 days. Baggage handlers in New York City, 400 employees of a transfer company, struck on August 25 for an eight-hour day and settled on September 16 for an increase of $1.00 per day.

A jurisdictional dispute between plasterers and bricklayers resulted first in strikes of plasterers in numerous cities beginning in June, and later in strikes of bricklayers. This dispute was settled in October at the convention of the American Federation of Labor by the mediation of President William Green. The Boston building trades employees struck on April 1 for wage increases. Settlements were made with several trades at various times and on various bases.

Strikes of bituminous coal miners were called in April by the United Mine Workers for union organization, first in northern West Virginia and then in the Panhandle district. These lasted through the year without conclusive results.

LABOR MEDIATION AND CONCILIATION

By George Soule

Editorial Department, New Republic

Conciliation Bureau.—The conciliation bureau of the United States Department of Labor in the first nine months of the year handled from 40 to 83 disputes each month, directly involving monthly known totals of from 19,000 to 42,000 employees. The smallest total of disputes handled was in August and September, the highest in April; the smallest total of employees known to be involved was in February, the largest in July. The number of disputes adjusted ranged between 20 in September and 48 in April.

Successful Conciliation. — There were few important cases of mediation or conciliation during the year. Attempts to mediate in the anthracite coal strike are described under "strikes and lockouts." An indirect result of the mediation by Governor Smith of New York in the cloak and suit industry during 1924, by means of the appointment of an investigating commission, was seen in the agreement reached on Feb. 24 between the New York Cloak, Suit, Dress and Reefer Makers' Union affiliated with the International Ladies' Garment Workers' Union, and the Association of Dress Manufacturers, fixing the conditions of employment of 30,000 dressmakers. This agreement provided new ways of determining piece rates, provided for the use of the "prosanis" label or sanitary union label on dresses manufactured in shops meeting the standards of the Joint Board of Sanitary Control, and installed a plan of unemployment insurance on the basis of a contribution of 2 per cent. of the weekly wage bill of manufacturers selling directly to the trade, and 1 per cent. of wages by all the workers. The fund was to be administered by a board of impartial trustees. Similar measures had previously been recommended by the Governor's Commission and adopted in the cloak trade.

Conflict with Labor Board.—The movement for a wage increase by the train-service brotherhoods inaugurated in 1924 was brought to a successful conclusion in the first half of 1925 by the signing of agreements between the engineers and firemen and the western railroads. This event was of significance because it marked the success of the attempt by these organizations to carry on negotiations with employers irrespective of the Railroad Labor Board. The general wage increase requested having been refused by the Conference Committee of Managers of the Western Railroads and negotiations having been broken off in May, 1924, the managers appealed to the Railroad Labor Board, which assumed jurisdiction of the dispute and set a date for a hearing.

The brotherhood executives objected to this procedure and announced their intention not to appear. They were subpœnaed by the Board and disobeyed the subpœna in order to make a test case. The subpœna was upheld by the U. S. District Court of Northern Illinois, but later voided by the Supreme Court of the United States. In the meantime the Labor Board, after the appearance of the managers at the hearing, had handed down a decision in the wage dispute which the brotherhoods declined to recognize.

Direct Adjustments with Railroads.—Instead, they entered direct negotiations with the Southern Pacific, and after a strike vote by the employees of that system succeeded in securing the agreement they wanted. The Conference Committee of Managers appealed to the Labor Board to set aside this agreement and enforce its own decision, but the Labor Board refused. Thereafter settlements with the individual western roads were made by the Brotherhoods along the lines of the Southern Pacific agreement. This incident greatly weakened the prestige and powers of the Railroad Labor Board. During most of the time this controversy was in progress the Brotherhoods were supporting a bill in Congress to abolish the Labor Board and substitute a different system of adjustment, while Chairman Hooper of the Board was issuing statements denouncing the executives of the Brotherhoods and defending the Board.

Controversy with the Pennsylvania Railroad.—During the year the Railroad Labor Board heard numerous other cases and handed down many decisions. The two most important were that of Jan. 16 raising the wages of railway clerks on 45 carriers, and that of Jan. 17 in a dispute between the Order of Railway Telegraphers and the Pennsylvania Railroad. A dispute having arisen between the telegraphers and the management, the management refused to recognize officials of the Order as representatives of its employees, but announced its intention to deal with representatives chosen according to its own employee representation system. The Order appealed to the Labor Board. The Board decided that the Order of Railroad Telegraphers was the genuine representative of the Pennsylvania telegraphers, and set a date for a hearing of the dispute. At this hearing the management failed to appear. This controversy was similar to several previous ones in which the Pennsylvania displaced national unions in favor of its own employee representation system, and refused to recognize decisions of the Labor Board concerning the conduct of elections or the question of representation.

Colorado Commission.—The only other governmental adjustment body of importance operating during the year was the Industrial Commission of Colorado. Under a state law no strike or lockout may be declared until the Commission has investigated the dispute and rendered a decision, acceptance of which is not compulsory. In April about 30 disputes arose concerning demands of coal mine managements for a 20 per cent. wage reduction. In about two-thirds of these cases the reduction was agreed to by the employees; in the other third the Commission decided in its favor. Later the Commission declined to sanction further reductions to the 1917 scale.

Impartial Chairmanship System.—The system of impartial chairmanship maintained jointly by union and employers to decide disputes arising under collective agreements in the men's clothing industry continued to operate successfully in Chicago, New York, Rochester, Baltimore and Milwaukee. Most of the decisions concerned technical matters and carried on the process of building up the "common law" of the industry. A similar system which had been set up two years previously by an agreement between the Haverhill shoe manufacturers and the Shoe Workers' Protective Union was abolished by vote of the workers, though there remained a possibility that it would be reëstablished by a new agreement in the course of the year 1926.

EMPLOYMENT

By John B. Andrews

Secretary, American Association for Labor Legislation

CONDITIONS

General Indices.—The general indices of employment from 1914 to 1925—compiled by the U. S. Bureau of Labor Statistics (*Monthly Labor Review,* November, 1925) from monthly reports of number of employees in over 9,000 manufacturing establishments of fifty-two industries in chief centers of the United States—using the average of monthly reports for 1923 as a base, were as follows:

1914	1915	1916	1917	1918	1919	1920	1921	1922	1923	1924	1925
94.9	97.0	110.4	115.0	114.2	108.2	109.9	85.1	88.4	100.0	90.3	90.8

The average was 90.8 for the first nine months of 1925 and showed an increase of employment of one-half of one per cent. over the average for 1924. The only years in which employment indices were lower were 1921 and 1922, while the indices for the two slack years 1914 and 1915, the greatest preceding depression, were considerably higher than for 1925. Comparison of the monthly indices for 1925 showed remarkable uniformity, the extremes being 92.3 for March and 89.3 for July. Comparison of groups of industries also revealed remarkable uniformity. The average indices for the twelve groups of manufacturing industries fell between 90 and 93.5, with the exception of manufactories of steel, iron and their products, and textiles and their products, which fell below 90, and paper and printing and stone, clay and glass products, employing relatively few workers, which averaged above 95. A more detailed examination of the steel and textile groups which together employ about half of all workers engaged in manufacturing, showed that in textiles, in which the general employment average was 89.1, the manufacture of cotton goods had the lowest average, 83.8. In the steel and iron group averaging 86.9 the manufacture of machine and foundry products and of stoves fell considerably below that of steel and iron itself.

Building Trades. — These indices, though based upon the manufacturing industries alone, which employ about one-third of the total number of wage workers, are the best single measure obtainable of the general condition of employment. Available statistics for other occupations tell much the same story. The number of employees on class I railroads for the first eight months of 1925 was 92.5 per cent. of the number in 1923. The slightly higher average than in manufacturing is doubtless chiefly due to shipment of materials used in construction, the one large industry which had steadily increased since 1923. Construction in 1920 employed less than one-twelfth of all wage workers. According to the index issued by the Associated General Contractors of America, based upon record of material shipments, the volume of construction in the United States, during the first seven months of 1925 was 5 per cent. greater than that for the corresponding period in 1924 and the total volume for 1924 was 4 per cent. greater than that for 1923.

Coal Mining and Agriculture.— Figures on employment in coal mines formerly furnished by the geological survey were no longer available. The latest official reports of the annual number of days' operation was for 1923, 179 days in bituminous and 268 days in anthracite mines, and for 1924, 171 in bituminous and 274 in anthracite, as compared with an average for the preceding ten years of 204 in bituminous and 251 in anthracite.

Satisfactory employment statistics on agricultural labor were, as always, lacking. Such as we have, chiefly from the Wisconsin Industrial Commission and U. S. Employment Service, indicate that demand for farm labor decreased from 1923 to 1925.

Over-developed Industries.—In his annual report for the year ending June 30, 1925, page 103, Secretary of Labor Davis says: "One of the great elements of the problem of unemployment . . . is the present over-developed state of some of our large industries. Our productive machinery and equipment in many of these industries cannot run for 300 days in the year without producing a stock that cannot be sold in this country nor in any or all other countries." He illustrates by figures from the 1920 United States Census in regard to several industries. In the boot and shoe industry there were 1,570 factories of which 227 or 14½ per cent. employed 60 per cent. of all workers in the industry and manufactured 65.6 per cent. of all boots and shoes produced, and could with steady work for 300 days a year produce all that could be sold. Similarly 12.8 per cent. of the flour mills, employing 42 per cent. of the workers, produced 62.1 per cent. of total barrels of product and could with full time work produce practically all the market demands. He adds:

"Go down the line and in nearly

every industry you will find the same appalling condition of affairs. What is needed is some system which will keep going only the coal mines and the manufacturing plants needed to produce what we need and can sell and to keep an adequate number of workers employed for 300 days in the year, while the unnecessary mines and plants can be closed or held in reserve. We need some system for scattering unneeded workers in any industry where they are really needed in industry yet to be developed. If this cannot be permitted under the existing laws, then there must be a way of modifying them so as to permit it without incurring any other more serious consequences."

Employment Service.—The director of the U. S. Employment Service reports coöperation with public employment agencies in 187 cities of thirty-nine states and the District of Columbia, which placed 1,609,977 wage earners during the year ending June 30, 1925. The farm labor division increased its activity by opening several new branch offices in the west. At the end of the year it served fully one-half the territory of the United States, meeting the seasonal labor needs of more than a dozen major crops. From a field activity supplying from 70,000 to 80,000 seasonal laborers in 1921 it had grown in three years to a service that in the year under review recruited and directed to employment more than 400,000 seasonal laborers to assist in caring for and harvesting farm crops valued at upward of two billion dollars. It also placed in monthly and yearly employment 16,411 farm hands. Secretary of Labor Davis, in his recommendations, states that the employment service can never realize the height of its usefulness until it becomes a statutory bureau with a permanent policy and program. We might add, and until adequate appropriation is provided. The federal appropriation for 1925 was $205,000 as compared with $206,284 in 1924 and $210,000 in 1923 and $400,000 in 1920. Six states, Iowa, Michigan, Minnesota, North Carolina, Oregon and Wisconsin strengthened regulation of private employment bureaus by legislative action in the course of the year 1925.

PUBLIC WORKS

Suggestion.—On January 12, President Coolidge in an address to the Associated General Contractors of America, recommended the idea of utilizing construction, particularly of public works, as a method of stabilizing employment in times of depression. He said: "Most forms of government construction could be handled in conformity to such a policy once it was definitely established." Unfortunately, when during the following month, millions of public money was being appropriated for government building construction, the national administration failed to exert itself in support of a provision for the application of the above principle.

Bill.—On February 11 the U. S. Senate Committee on Public Buildings and Grounds held a hearing on the bill authorizing the appropriation of $150,000,000 for public buildings, not more than $25,000,000 to be spent *in any year*. An amendment was presented permitting more than $25,000,000 to be spent in years of industrial depression and unemployment in order to stabilize industry and employment.

Otto T. Mallery presented resolutions and communications from the President's Conference on Unemployment, the American Engineering Council representing about three-fourths of the engineers of the country, the Associated General Contractors of America, the American Association for Labor Legislation, all organizations in whose behalf he spoke. The bill was withdrawn with the expectation of revival in the next Congress.

Proposed Department of Public Works.—The American Engineering Council, assisted by an advisory council representing organizations engaged for the most part in engineering, architecture and construction, continued to prepare for a campaign to create a department of public works in the executive arm of the United States government, which would facilitate coördinated planning for public works in times of depression.

Bankers' interest in such a movement was indicated by a bulletin issued in 1925 by the Chase National Bank of the City of New York, which advocated long-time programs of federal, state and municipal construction with a view to timing public expenditures to periods of business depression and provision of state revolving funds for working capital to alleviate injudicious borrowing.

A bill providing for advance planning of public works and a reserve fund of $50,000 for periods of industrial depression was introduced in the Massachusetts legislature and was referred by both houses to the next annual session.

Unemployment Insurance. — The former Huber bill providing for unemployment compensation was re-introduced by Senator Heck in the Wisconsin legislature and similar bills were introduced in Minnesota and discussed in Illinois and California.

Probably the greatest advance in unemployment relief was along the line of unemployment insurance through funds created by joint agreement and contributions of trade unions and employers (*International Labour Review*, March, 1925, pp. 318-328). This arrangement in the Chicago Amalgamated Clothing industry had been functioning since April, 1923. During the year ending April 30, 1925, $1,609,629 was paid in unemployment benefits to workers. Contributions for the two years were over $2,000,000. The expense of administration amounted to only 5 per cent. of the total income and difficulties of administration were notably few. (*Monthly Labor Review*, November, 1925, p. 133.)

Funds established in New York by the International Ladies' Garment Workers' Union and employers and by the hat and cap industry, had been paying benefits since June, 1925. Similar arrangements had been established for the International Ladies' Garment Workers of Cleveland, Ohio, and hat and cap makers of all the principal markets, including Boston, Philadelphia, Chicago, St. Paul, and Baltimore. (*American Labor Legislation Review*, September, 1925.) According to the National Industrial Conference Board, 134,000 workers were thus protected, including workers in the wall paper industry in nineteen plants in various sections of the United States. (*Industrial News Survey*, May 25, 1925.)

Unemployment Funds.—Unemployment funds were inaugurated by employers in an increasing number of plants. The president of a large life insurance company announced in December that his company was ready to undertake the experiment of unemployment insurance if the necessary amendment of state insurance laws could be obtained. His proposed system would resemble group health insurance to which both employer and employees would contribute.

WORKMEN'S COMPENSATION AND HEALTH INSURANCE

By Paul H. Douglas

Professor at University of Chicago

Extent.—In 1925 some slight gains were made in the liberalization of the laws providing compensation for workmen injured in industry. The legislature of one additional state, Missouri, enacted such a measure but a popular referendum on the act has been called for 1926. If it is ratified, Missouri will be the forty-third state to have such a law. The five other states without such a measure are Arkansas, Mississippi, Florida, South Carolina and North Carolina. Congress has not yet provided such a system for private employment in the District of Columbia.

Fields.—These laws generally cover the field of manufacturing but interstate commerce is exempted as is agriculture and domestic service, save in the case of New Jersey. In fourteen jurisdictions, employers in the lines of industry covered by the act must come under its provisions, but in thirty-two they may elect whether or not to do so. Those who in this latter group of states refuse to come under the scope of these laws lose the three common-law defenses of assumption of risk, contributory negligence and negligence of a fellow-servant which were their chief legal bulwarks under the system of employers' liability. The vast majority of employers for these reasons do choose to come under the compensation laws.

In thirteen states the law is now so interpreted as to apply to the clearer cases of occupational diseases as well as to accidents. Save in South Dakota and Oregon, a waiting period is required after the disability is incurred for which no compensation is paid. There has been a noticeable tendency in recent years to decrease the length of this period and in nearly two-thirds of the jurisdictions it is now seven days. In several states, however, ten and fourteen day waiting periods prevail and among these is Pennsylvania.

Types of Benefits.—The two types of benefit provided are (1) cash and (2) medical and hospital care. There are four main types of industrial injury for which cash compensation is paid, namely, temporary total, permanent partial, and permanent total disability, and death. The amount paid out is limited in three further ways, namely, (*a*) by allowing compensation to be paid only up to a certain percentage of the worker's wage; (*b*) by fixing a maximum amount in dollars which can be paid weekly; and (*c*) in the case of permanent injuries and of death, by limiting the number of weeks during which compensation may be paid.

Amounts.—Nearly one-half of the jurisdictions allow less than 60 per cent. of the worker's wage, although there are seventeen that prescribe either 65 per cent. or two-thirds. Eight states, including Pennsylvania, Indiana and Michigan, allow less than $15 a week as a maximum, while only nine permit more than $18 a week to be paid. When these are combined with the waiting period provisions, the proportion of the financial loss which is thrown back upon the shoulders of the injured workmen is startling. Thus a worker in Pennsylvania who was earning $40 a week and was disabled for four weeks would not receive any compensation at all for the first ten days and only $12 a week for the remaining two and a half weeks. The total amount of compensation paid would therefore be $30, or less than 20 per cent. of the wage loss that the worker had suffered.

The benefits for death and permanent total disability are generally not allowed for more than a given number of weeks. For death this ranges between five and ten years, while for permanent disability there is a tendency to allow a longer period of time. A number of states also graduate the percentages of earnings which are paid in these cases according to the number dependent upon the worker.

Permanent partial disabilities, such as the loss of a hand or other member, are compensated for either by the payment of compensation for a given number of weeks, or by a percentage of the loss in actual earning capacity which the worker suffered. All of the jurisdictions now provide for some medical attention although the amounts permitted are in general too low.

Insurance by Employers.—In order to protect the injured workers from possible loss through the bankruptcy of their employers, virtually every state requires the employers to insure. The three main agencies for this purpose are: (1) private insurance companies, which are generally stock companies although mutual associations of employers are quite strong in Massachusetts; (2) Self-insurance, if the employing body is sufficiently large and is solvent. This, however, is prohibited in Massachusetts; (3) State funds, which may be given a monopoly of the business as in Nevada, North Dakota, Ohio, Oregon, Porto Rico, Washington, West Virginia and Wyoming or may merely compete with private agencies as in the other states, of which the most notable example are the funds of California, New York and Pennsylvania.

Inadequacies.—The chief inadequacies of our workmen's compensation laws lie in the insufficient benefits that are paid. Dr. E. H. Downey estimated that taking the country as a whole, industry bore only "one-third of the economic cost of those injuries which are subject to compensation." When allowance was made for those industries and employees who did not come within the scope of the laws, he declared that "four-fifths of the wage loss resulting from injuries in the course of employment still falls upon the individual victims thereof." The laws are being slowly liberalized but much more rapid progress is needed if the burden of industrial accidents is to be placed in practice, as well as in theory, upon the industry itself. The chief lines of reform would seem to include: (1) the widening of the scope of compensation legislation to include more states, together with such exempted employments as inter-state commerce; (2) the shortening of the waiting period to at least one week and preferably to three days; (3) the raising of the proportion of wages to be paid to approximately two-thirds; (4) either abolishing the maximum limit to be paid per week or greatly increasing it to allow for the great increase of money incomes in recent years; (5) the granting of longer periods of benefit in the case of death or total disability; (6) the graduation of disability benefits according to the number dependent upon the worker; (7) the granting of an increased amount of medical and hospital care.

Health Insurance Movement.—The organized movement to secure the passage by the various states of compulsory health insurance laws which would provide medical and cash benefits during the illness of industrial wage-earners has for the present spent its momentum. This movement was led by the American Association for Labor Legislation. A number of powerful groups came to oppose it, including the private insurance companies, the major part of the medical profession, the Christian Scientists, and the general run of business men. The post-war reaction against social legislation of all varieties directly operated against the passage of such laws, while the failure of the American Federation of Labor to support the proposal deprived the movement of its strongest potential source of support.

Voluntary Health Insurance.—But while compulsory health insurance has been defeated for at least the present, there has been an increasing voluntary installation by business firms of various forms of benefit associations, now numbering over 800, which assist the workers in the given company during the periods of their illness. The forms which these benefit associations take are many. The workers are the sole contributors to some; the employers to others, while many are supported by joint contributions. The management of the funds tends to be parallel with the source of the contributions. The cash benefits paid are sometimes flat sums but in other instances are graduated according to the earnings of the worker.

An interesting experiment has been carried on for a number of years in Flint, Michigan, where a number of firms have coöperated to set up and maintain an interplant fund and a common medical service for the employees of the several companies.

OLD AGE PENSIONS

By Paul H. Douglas

Professor at the University of Chicago

Public Systems.—The old age pension movement in this country is growing from two sources. The first is through the passage of pension acts by state legislatures, while the second is by the establishment of such systems by private corporations. In 1923, as a result of the active campaign which was carried on by the Fraternal Order of Eagles, the states of Nevada, Montana, and Pennsylvania passed substantially similar pension acts. For a person to satisfy the requirements for eligibility, the Pennsylvania and Montana statutes required that he be seventy years of age; in Nevada sixty years; residence of fifteen years in Pennsylvania; ten years in Nevada.

The amounts to be paid out in pensions were to be adjusted in each specific case, but together with all other income of the recipient, the maximum must not exceed $7 a week in Pennsylvania and $25 a month in Montana.

The financial burden of payment was placed upon the countries, with general supervision of expenditures by a state board. The total number granted pensions in the three states was approximately 3,100. The average pension granted in Montana amounted to $87 a year, in Nevada to $240 and in Pennsylvania to $244. In 1924 the Pennsylvania law was declared by the courts invalid on the ground that it violated a provision in the state constitution forbidding charitable grants of public money to private individuals. In 1925, Wisconsin passed an old age pension act modelled upon the lines of the Pennsylvania law, and a grant of $200,000 from the state treasury assisted the counties in bearing the financial burden.

Private Systems.—Within recent years a large number of private companies have adopted old age pension plans for their employees. These are of two main kinds, non-contributory, in which the company bears all the expense, and contributory, in which it is jointly met. Both types usually require that the recipient must reach a given age, generally 60 or 65, and a length of employment by the company, which ranges from 15 to 25 years. A requirement for continuous service is a strong force tending to prevent the older employees from going out on strike.

The amount of the annual pension is generally determined by multiplying the average earnings over a period of years by the number of years worked, and taking some fraction of the result, generally 1 or 2 per cent. In contributory funds, the worker upon withdrawing from the company, almost invariably has a right to the amount which he has contributed. Dependents are also given rights in case of the death of the workman before or after reaching the pensionable age.

Absorption of Concerns.—A very important case bearing on the rights of workers to such pensions was decided in the Illinois courts in 1925. In 1909, Morris and Company, the large meat packers, instituted a contributory pension plan. This firm was afterward absorbed by Armour and Company; and the new owners, because of the expense involved, altered some of the features of the pension system. A number of workers brought suit to recover the privileges which were theirs under the original plan. Amongst other points, they alleged that in some cases the prospects of a pension had been used to retain men in the employ of the company at less wages than they could have secured in the market. The pensions were therefore, it was claimed, in the nature of deferred pay and should not have been taken away from the men who had in reality earned them. The court ruled, however, that the company's contribution to the pension fund was in the nature of a gratuity which could be withdrawn at will.

Insurance System.—The Metropolitan Life Insurance Company has developed a pay-as-you-go pension plan whereby an employer may give to each worker at the end of each year of service, a certificate entitling him to an annual income of $10 when the worker reaches the age of, say, sixty-five. This means that the worker will secure some protection for old age, growing with each year's work. It will consequently not be necessary for him to serve the full quota of years of service before he can secure anything.

WAGES AND HOURS OF LABOR

By John Gould Curtis
Of the Pennsylvania Bar

Basis of Wages.—Throughout the industrial world the tendency has become more and more marked to treat the rising or falling costs of staple commodities as a reason, if not an actual basis, for the readjustment upward or downward of the scales of payment to wage-earning employees. Any discussion of wage rates is inevitably accompanied by elaborate tables indicating the cost of living in the community under consideration, such tables being commonly referred to the standard of the last prewar year, 1913.

An able, impartial, and exhaustive compilation of statistical material is to be found in the *Monthly Labor Review*, published by the Bureau of Labor Statistics of the Department of Labor. For the most part its records are substantially contemporary; that is to say, published within a few months of the time to which they relate. Occasionally the statistical tables cover previous years. They are too elaborate to be reproduced here in detail, but summary material may be presented.

Living Costs.—Thus the per cent. of increase in cost of specified food articles on January 15 of each specified year, compared with January 15, 1913, shows summary figures as follows:

1919	88.4	1923	46.9
1920	104.8	1924	51.7
1921	75.4	1925	57.0
1922	44.5		

These figures are based on nation-wide reports of prices of common cuts of meat, poultry, canned salmon, fresh and evaporated milk, butter, oleomargarine, cheese, lard, eggs, bread, flour, cereals, macaroni, rice, navy beans, potatoes, onions, cabbage, canned vegetables, sugar, tea, coffee and common fruits. These are commodities essential to a well-balanced, varied and palatable diet, and it seems conceded that workingmen ought to be able to earn enough to make reasonable provision for themselves and their families.

As compared with January 15, 1924, average food costs on January 15, 1925, were but 3.5 per cent. higher, articles which had varied in excess of 10 per cent. were:

Pork chops	+ 12
Butter	— 15
Lard	+ 22
Eggs, strictly fresh........	+ 29
Eggs, storage	+ 39
Flour	+ 33
Corn meal	+ 23
Corn flakes	+ 12
Potatoes	— 11
Corn, canned	+ 11
Sugar, granulated	— 21
Coffee	+ 35
Bananas	— 14
Oranges	+ 12

The substantial increase in cost of many important staples makes it obvious that living expenses increased rather more than the 3.5 per cent. average would indicate. Prices on September 15, 1925, show an average advance of 8.3 per cent over those for September 15, 1924.

Coal, an essential in almost every home, is slightly less costly than it was in 1924; the same is true of clothing.

Purchasing Power.—In the purchase of all commodities, the dollar of 1913 is worth more than it was in 1920 but has been losing ground since 1921.

The purchasing power in cents for June in each of the years listed was:

1920	41.1	1923	65.1
1921	70.6	1924	69.2
1922	66.8	1925	63.5

Wages have in general tended upward as the dollar has become less valuable; an elaborate tabulation covering twenty occupations and forty principal cities from 1913 to 1925 may be found in the Monthly Labor Review, XXI, 54-76.

Hours of Labor.—These are recorded also in the table just referred to. The 44-hour week is strikingly preponderant throughout the unionized occupations, with the notable exception of newspaper compositors and typesetting-machine operators. The year has witnessed no general or marked change in this respect.

It is pertinent to observe that the diminution of working hours and the frequently concomitant increase in weekly wage, as compared with earlier years, has in many instances resulted in a lessened labor cost per unit of the finished product in manufacturing industries. Secretary of Labor Davis has pointed out that the increase wrought in the value of raw material by manufacturing processes in 1923 was 41.1 per cent. greater than in 1921, although the number of workers increased only 26.2 per cent. and the amount of wages paid, 34 per cent. This increased efficiency of the individual employee must be considered in weighing the justice of his claim for an increased reward.

Agricultural Labor.—Farmers have been for so long dependent upon migratory labor that it is difficult to make them appreciate the value of budgeting their labor requirements, so to say, and filling them through established state or federal agencies instead of engaging applicants who come to the gate. The former method makes possible the securing of experienced workers from adjacent communities—reliable and reputable individuals who may be reëmployed from year to year, to their own advantage as well as that of the farmer. The Farm Labor Bureau of the Department of Labor Employment Service mobilized through its Kansas City office, in 1924, 100,000 wheat harvesters, 200,000 cotton pickers, and other workers bringing the total to nearly half a million for the season. The Oregon Department of Labor exemplifies a first-rate state enterprise with the difficult problem of marshaling workers to care for various crops from the strawberry harvest in May until the last of the Hood River apples are picked in November.

Farm employment has been unattractive for years because of the long hours that it involved; more recently, farm employers, in recognition of this feeling and as a concession to the aversion for the old sunrise-to-dark agricultural work-day, have taken steps to put agricultural labor on something more nearly approaching a shop basis. There has been no general organization, but assistance was becoming hard to get, and the need for help had to be weighed against the giving up of an immemorial custom; the custom is losing.

Agricultural wages.—These have, from the nature of things, ordinarily included board and shelter. Figures are available showing the average prevailing monthly farm wage rates, both with and without board, but the rates without board are alone reprinted here:—

	United States	North Atlantic States	East North Central States	West North Central States	South Atlantic States	South Central States	Western States
1920	$65.05	$76.18	$70.71	$80.12	$47.37	$52.07	$99.81
1921	43.58	57.92	49.19	50.33	31.31	33.21	68.82
1922	42.09	56.51	47.03	47.59	30.71	32.16	66.98
1923	46.74	63.54	53.81	52.67	34.75	35.06	72.24
1924	47.22	65.58	53.80	51.22	36.06	36.19	71.25
1925							
Jan. 1 ..	45.04	62.42	50.39	46.20	35.37	35.25	69.29
Apr. 1 ..	47.40	66.30	54.10	52.89	36.03	35.55	71.42
July 1 ..	48.55	67.34	54.45	54.14	37.41	36.56	73.74

Timber Industry.—In the summer of 1925 an elaborate survey of labor in sawmills was undertaken, and statistics gathered from mill payrolls were compiled and published in the Monthly Labor Review, XXI, 978. To take the two most significant classes of employment: in 274 establishments, 644 head band-sawyers were employed an average of 57.7 full-time hours per week at an average of $0.877 per hour or $50.60 per week; earnings ranged from $39.67 per week in Pennsylvania to $63.54 in Florida. In 299 establishments, 36,698 laborers were employed an average of 57.5 full-time hours per week at an average of $0.309 per hour or $17.77 per week; earnings ranged from $10.48 per week in South Carolina to $25.27 in California.

Index numbers have also been compiled, showing full-time hours per week, earnings per hour, and full-time earnings per week in the lumber industry in specified years. These are referred to the 1913 basis; thus the index number 92 in the first column for 1919 indicates that the number of full-time hours per week in that year was 8 per cent. less than in 1913. But except with reference to 1913 the figures cannot be interpreted in percentages; thus the per cent. of increase for 1921, represented by the index 94, over 1919, must be obtained by dividing the index for the later year into that for the previous one.

Year	Full-time Hours per Week	Earnings per Hour	Full-time Earnings per Week
1913......	100	100	100
1915......	100	91	91
1919......	92	194	179
1921......	94	166	156
1923......	94	180	170
1925......	94	178	168

Mines.—One of the outstanding problems of the past year, as of several previous ones, has been in the anthracite coal mines of Pennsylvania. The frequent strikes have been of marked significance because of the wide reliance on anthracite coal for household use, the small stocks commonly kept on hand by individual consumers, and the consequent promptly felt effects of a cessation of supply.

The agreement reached in 1923, and in force until August 31, 1925, was arrived at following the recommendations of Governor Pinchot; it confirmed the award of the Anthracite Coal Strike Commission of 1920, and subsequent agreements, except in details specified (*Monthly Labor Review*, XXI, 81), which amount substantially to allowing a 10 per cent. increase in wage to mine laborers. An effort to secure further concessions from the operators on the expiration of this agreement was unsuccessful; detailed reports of the conferences are not yet available.

A summary of wages and hours of labor in metalliferous mines, as of the summer of 1924, has been printed in the *Monthly Labor Review*, XX, 1033. It covers 117 underground and 20 open-pit mines in fourteen states, and tabulates the hours and earnings of each class of labor in each of the groups of mines.

Manufactures.—It is impossible to undertake here any survey of manufacturing industries generally throughout the country. Figures from the New York State Department of Labor are, however, of especial value because they show the variation between city wages and those for the state generally; the following limited table was compiled to show average weekly earnings for May, 1925:

Industry	All Employees		Shop Employees, State	
	Whole State	N. Y. City	Men	Women
Stone, clay, glass......................	$28.87	$37.36	$30.59	$15.05
Metals, machinery and conveyances........	30.56	29.61	31.69	16.51
Wood manufactures	27.80	29.97	29.03	16.31
Furs, leather, rubber....................	26.06	28.70	27.97	16.14
Textiles	22.11	22.93	26.93	15.68
Clothing, millinery, laundering, etc........	23.82	27.16	30.55	17.54
Food, beverages, tobacco................	26.41	26.33	30.84	16.85
Water, light, power.....................	34.01	33.14	34.01	....
Grand total	$28.07	$29.30	$31.33	$16.96

The Industrial Bulletin of the New York State Department of Labor published in August, 1925, statistics on the average weekly earnings in representative New York State factories. 1914 to 1925. The figure for 1925 is based on the first seven months only. All employees in both office and shop are included.

1914	$12.48	1920	$28.15
1915	12.85	1921	25.72
1916	14.43	1922	25.04
1917	16.37	1923	27.24
1918	20.35	1924	27.68
1919	23.50	1925	28.05

There is available also a general index of pay-roll totals in manufacturing industries, to June, 1925; these are based on nation-wide reports, and the index is referred to the standard of 1913:—

1916	$61.9	1919	103.6
1917	76.3	1920	125.9
1918	96.7	1921	80.0
1922	79.9	1924	90.6
1923	100.0	1925	93.7

Transportation.—No compilations of statistics relating to railroad employees are available; but the decisions and awards of the Railway Labor Board are published currently in the *Monthly Labor Review* and desired information as to the present condition of any specific employment may be found there.

Illuminating information on the wages of seamen, as of January 1, 1924, is to be found in the *Monthly Labor Review*, XX, 1039. American seamen are altogether better paid than those of any other nation, with the exception of cooks and members of the engineer's department, toward whom the French are especially generous; Shipping Board employees enjoy for the most part slightly higher wages than those on privately owned ships.

LABOR REPRESENTATION IN BUSINESS MANAGEMENT

By Paul H. Douglas

Professor at the University of Chicago

Works Councils.—Perhaps the most noteworthy development of the last six years in the field of industrial relations has been the growth of works councils, or, as they are frequently called, shop committees. These are bodies which represent the workers in an individual plant or company, and which deal with their common employer. They differ from the union type of organization in that the latter combines the workers of a number of concerns into one organization and then bargains not so much with individual employers as with those of the locality or trade as a group.

The growth of the movement in recent years is shown by the National Industrial Conference Board to have been as follows:

Year	Number of Work Councils	Number of Employees Covered by Plans
1919.........	225	391,000
1922.........	725	690,000
1924.........	814	1,177,000

The works council movement at the present time includes approximately one-third as many workers as the trade-unions of the country. These councils are almost wholly confined to "open shop" firms that do not deal collectively with the unions and hence form intra-shop agencies for collective bargaining. This is in sharp contrast to the works councils of England and Germany which exist primarily in unionized shops, with the wage scale for the industry fixed by agreement between the unions and the employers' associations.

Size of the Councils.—The works councils are predominantly confined to those large establishments where personal relations have broken down but where the unions have not been strong enough to gain a foothold. Only 43,000 of the wage-earners that come under the scope of the council system are in firms employing under 1,000 workers. One and one-eighth million are in firms with over 1,000 workers; and over seven hundred thousand are in firms employing over 15,000 persons. Approximately one-third of the employees in manufacturing and railroading enterprises with over a thousand workers are represented by some form of shop committee.

Types.—There are three main structural forms of employee representation. The first is the simple town-meeting form practised by small firms such as the Columbia Conserve Company and by such larger firms as the A. Nash Company. Here a general meeting of the employees is held. This is patently more adapted to smaller concerns than to the larger. The second is the governmental or so-called "industrial democracy" type fostered by Mr. John Leitch. This consists of a House of Representatives elected by the workers, a Senate comprised of the foremen, and a Cabinet composed of the executives. The difficulties created by this separation of the groups have led a number of companies to dissolve the senate and to provide for joint meetings, and thus to merge into the third type. This is one of joint committees where representatives of both groups meet to discuss and to pass upon certain problems. This is by far the predominant type and is characteristic of such large concerns as the Pennsylvania Railroad, the Colorado Fuel and Iron Company, the International Harvester Company, the various Standard Oil Companies, the large meat packing firms and such important public utilities as the Peoples Gas, Light, and Coke and the Commonwealth Edison Companies of Chicago. In addition to these types of representation, some companies, such as Procter and Gamble, and the Dutchers Bleachery, have representatives of the manual workers upon the Boards of Directors.

Authority of Councils.—An examination of the constitutions and activities of these councils indicates that in by far the vast majority of cases, the works councils have only advisory powers. This is clearly the case in the industrial democracy plans where the Senate or Cabinet may negative the proposals of the House. In the great preponderance of cases, the decisions of the joint councils even when made are not finally binding upon the executives, while in the event of deadlock between the two groups on the joint council, arbitration is rarely compulsory. Exceptions to this latter tendency are however the Philadelphia Rapid Transit Company, the Peoples Gas, Light and Coke Company, and the Commonwealth Edison Company of Chicago.

Results.—The various plans have without doubt been of use in helping to restore the personal relationship between the executives and the manual workers. They have facilitated the adjustment of personal grievances and have in some cases led to increased production on the part of the men. The chief point at issue is as to whether they are an adequate substitute for unionism. Recent studies by the Russell Sage Foundation of the employee representation plans of the Colorado Fuel and Iron Company and the Dutchers Bleachery show that the basic wage scales in these companies depend on the prevailing rates in their industry as a whole. The council is relatively powerless to keep wages in any one company much, if at all, above the competitive level. This is openly stated in the basic agreements covering the plans of the Colorado Fuel and Iron Company, the Standard Oil Company, the Philadelphia Rapid Transit Company and is acted upon in other companies as well.

Some students of the subject have pointed out that in an industry which is not unionized, the employees of a company with a shop committee are in a relatively helpless position. The pressure of the wage-cuts in other plants forces even such philanthropically minded employers as the Dutchers Bleachery to reduce wages. In a unionized industry, however, the strength of the union makes wage-cuts more difficult and perhaps increases wages more readily. This makes it possible for the plants with shop committees either not to cut wages or to increase them. But these gains (in general), it is pointed out, are dependent upon the efforts of the unions and not upon those of the shop committees.

Disagreements.—Finally, it is queried, aside from those cases where arbitration is compulsory, what recourse have the workers under the shop committee system, if they disagree with the employers? They have virtually no funds to sustain them if they were to strike; nor would organized workers feel any loyalty to them; and hence it would not be very difficult to secure others to take their place. If organized in a union, they would be strengthened in both these respects; and this would enable them to secure a more favorable division of the product.

In brief, it seems probable that the shop committee system is admirably adapted to secure an increase in the total amount of the product and to make local adjustments much less difficult. From the standpoint of the workers, it would seem inferior, however, to unionism in securing for the workers a larger share of the product. A combination of the two types of organization would, therefore, appear to be desirable. This combination is being worked out with conspicuous success in the men's clothing industry and in the repair shops of a number of railroad companies.

LABOR COLLECTIVE BARGAINING

By Paul H. Douglas
Professor at the University of Chicago

Trade-unionism has its greatest strength in the five industrial groups of coal mining, building, transportation, clothing, and printing. In 1923 the union membership in these industries included approximately 2,700,000 workers, or 70 per cent. of the total number of those in trade unions in this country. There is comparatively little unionization in the iron and steel mills, or in the metal, chemical, rubber, lumber, meat-packing, and automobile industries. Collective agreements are consequently few in these industries and such union men as are employed are generally found working along with non-union employees.

Since effective unionism is largely confined to the five industrial groups first enumerated, the major part of our attention should be devoted to them. The miners' union was engaged in a difficult struggle throughout 1925. The Jacksonville agreement of 1924 provided for the continuance of the then existing wage scale during the next five years in the central competitive field. The union, however, did not succeed in successfully unionizing the southern counties of West Virginia, nor those of Kentucky and of Somerset County, Pennsylvania. These mines, many of which are favored with thick seams of coal, resumed operations at an appreciably lower wage scale than those of the union districts. They were consequently able to undersell most of the mines in the unionized districts, and to take a large part of the market away from those with union agreements. This result was enhanced by the fact that a large percentage of mine capacity is never utilized and this likelihood of suspension of work consequently tends to concentrate itself upon those mines with high unit costs. The business relapse since 1923 has decreased the industrial demand for coal and therefore increased the idle capacity of the industry. The union mines in the central competitive field have in consequence been scarcely able to offer three days of employment per week and in many cases even less. The employers in union mines consequently are anxious to have the Jacksonville scale reduced in order that they may compete more successfully, but this the union has refused to permit. A number of mine operators in the central part of West Virginia have canceled their agreements and are now operating on a non-union basis with a lower wage scale. Other union operators are distinctly restive and it seems an open question whether the union can long maintain the Jacksonville scale.

The agreement in the anthracite branch of the industry expired in September, 1925. The miners demanded a new contract which would embody the following principles: (1) a 10 per cent. increase in tonnage rates and a flat raise of $1 a day for the day workers; (2) the establishment of the "check-off" system whereby union membership is made compulsory. Under this system the coal companies deduct the union dues from the pay of the workers and turn the receipts over to the unions. This practice is followed in the unionized districts of the soft coal industry. (3) The improvement of a number of working conditions, such as freeing the owners from paying for the miners' tools; allowing them to take charge of paying their own laborers; and providing an increased number of openings in their veins to permit more ventilation. The mine operators refused to agree to these conditions, but suggested arbitration, which President Lewis of the miners rejected on the ground that from past experience the men could not trust arbitrators. On September 1, 1925, virtually all the anthracite miners, to the number of 150,000, went out on strike. At the time of writing (November 15), the struggle was still deadlocked and there were no immediate prospects of settlement.

Few changes are noted in the building situation during the year. Construction continued briskly and union wage rates rose slightly. The campaign waged by the employers in Chicago against certain building trades unions that refused in 1922 to conform to the arbitration decision of Judge Landis, seemed to have spent its force; and the unions were recovering their strength. In New York, the building trades unions were still as strong as ever, certainly in most of the large cities in the East and Middle West. In the smaller cities and towns, however, their hold was much less secure, while in the South the non-union shop was more characteristic. In California the employers' associations seemed to be maintaining the supremacy which they had previously gained.

The chief event in the clothing industry has been the gradual inclusion in trade agreements of provisions granting protection against unemployment, jointly financed by employers and workers. The agreement negotiated in 1923 in the Chicago market by the Amalgamated Clothing Workers was the first to set up such a fund. During the year a similar fund has been established in the New York market of the same industry. The new agreement negotiated by the International Ladies' Garment Workers for the women's clothing industry of New York City also provides for an unemployment insurance fund, as do those secured by the Cloth Hat and Cap Makers in the New York, Baltimore, Philadelphia and St. Paul markets.

The difficulties of maintaining a stable agreement in the women's clothing industry of New York have been heightened by the increasing tendency of the industry to split up into a large number of small contract shops. Supervision over these and the maintenance of uniform standards of hours and wages have become more difficult. In the men's clothing industry perhaps the most sensational event of the year has been the prolonged strike in the Chicago and New York factories of the International Tailoring Company, which resulted from the refusal of the company to negotiate a new contract with the Amalgamated Clothing Workers and which eventuated in a victory for the union.

In the newspaper printing industry, the unions have maintained their strong position. Only three or four of the important newspapers in the country maintain non-union shops, and the recent attempt to augment this number has failed. The unions have not fared so well in the job printing industry. The 1921 strike for the 44-hour week lost them agreements in a large number of the cities; while the International Typographical Union paid out seven million dollars in strike benefits. The pressmen, whose funds were much more meagre, fared even worse than the printers. New York and Chicago are the main centers where union agreements prevail, and the non-union group in the latter city has increased relatively during the last few years.

Collective bargaining on the railways is largely confined to the train service workers and to clerical employees. The various shop craft unions suffered such losses in the 1922 strike that, excepting on a few roads, they have not been a strong factor since.

The train service crafts are now dealing directly with the roads rather than resorting to the Railway Labor Board for the settlement of disputes. The clerks, on the other hand, who naturally are not as strong as the train-service Brotherhoods, are utilizing the services of the Board in the adjustment of grievances.

LABOR LEGISLATION

By Irene Osgood Andrews

Assistant Secretary, American Association for Labor Legislation

Workmen's Compensation. — In 1925 the Federal Congress and legislatures of forty-two states, Alaska, the Philippines, Hawaii and Porto Rico held regular sessions. Three of these states also held special sessions. Notable advance was made in the field of workmen's compensation. The legislature of Missouri enacted an elective law of fairly liberal provisions to be administered by a commission of three members. This act was approved both by business interests and the American Federation of Labor. But the opposition, led by the legal profession and a small section of organized labor, succeeded in suspending the law by referendum petition and it will be submitted to vote of the people at the 1926 November election. Arizona repealed its existing compensation law and enacted a much better one, providing for a competitive state fund and an industrial commission of three members to administer all state labor laws. This act and a constitutional amendment providing for its legality were submitted to referendum vote at special election in September and they were ratified, thus placing Arizona in the list of states having a good modern compensation law.

Twenty-three other states, Alaska and Porto Rico amended their workmen's compensation laws. New Jersey reduced the waiting period from ten to seven days while Porto Rico established a waiting period of seven days. The new Missouri law provides a waiting period of three days, retroactive after three weeks, that of Arizona one of seven days, retroactive after two weeks. Porto Rico now covers all farm workers instead of certain specified types; employers' election in Wisconsin may now include farm workers and domestics while Montana specifically lists excluded agricultural occupations and provides for their voluntary covering. A dozen states extend coverage to certain classes of employees. Alaska and Arizona, by providing for medical care, make this provision common to all our state compensation laws. Illinois removed time and cost limits, while Montana, Nevada, Ohio, West Virginia, Wisconsin and Wyoming liberalized provisions for medical care.

Benefits to Minors.—Compensation to illegally employed minors in Wisconsin, formerly treble in all cases, is made treble for prohibited employments and double for failure to obtain permit. Oregon provided benefits for illegitimate children. Death benefits varying with the number of dependent children were provided in Arizona and increased in Illinois, Minnesota, Nevada and Wisconsin. In Illinois disability benefits depending upon the number of children were also increased. Montana now compensates aliens and minors whether or not legally employed, the age limit of dependent minors was raised from sixteen to eighteen years and death benefits to parents increased from 40 per cent. to 50 per cent. of wages. North Dakota provided that compensation for minors and learners be revised from time to time. Maximum weekly benefits were raised in Connecticut, Illinois, Maine, Montana and Porto Rico, and minimum weekly benefits in West Virginia and Montana. Porto Rico changed occupational disease coverage from the general to the specified list type, while Ohio and North Dakota liberalized occupational disease provisions. The federal law extended compensation benefits to enlisted men injured in times of peace, excluding for this purpose cases due to sickness or disease, while New Jersey extended naval militia workmen's compensation benefits to members of the national guard, including cases of death or disability caused by any disease due to service without regard to the occupational disease list in the workmen's compensation act.

Vocational Rehabilitation. — The provisions of the federal vocational rehabilitation act were accepted by Colorado, New Hampshire and Oklahoma, making thirty-nine states and Hawaii now coöperating. Congress made annual appropriation of $914,000 for carrying out the provisions of the act. New York extended its vocational rehabilitation act to cover all children under fourteen years of age who by reason of physical defect other than blindness or deafness may be expected to be wholly or partially incapacitated for education or remunerative occupation. The State Commissioner of Charities is made a member of the ex-officio advisory commission for oversight of rehabilitation work. Montana provided a monthly maintenance allowance, in addition to benefits formerly received, for certain persons under the direction of the state rehabilitation bureau. New York provided additional compensation for general rehabilitation purposes to be paid out of the maintenance fund but still limited the allowance for maintenance to $10 per week.

Child Labor Laws.—The child labor amendment to the federal constitution was ratified by Arizona, California and Wisconsin. Georgia and New Mexico materially strengthened their child labor laws by forbidding children under sixteen to work in an enumerated list of occupations including operation of dangerous machinery, processes using poisonous substances and any occupation dangerous to life or injurious to health or morals, by making more specific the conditions for issuing work certificates, and by other provisions. Wisconsin authorized its industrial commission to investigate conditions of employment of children under sixteen and to fix by general or special order reasonable regulations for protection of such children in certain industries including gardening for market or canning companies, culture of sugar beets, cranberries, and cherry orchards. Laws affecting child labor of nine other states and the District of Columbia were improved in minor particulars. In Delaware and Rhode Island commissions are authorized to investigate laws relating to children.

Coal Mine Safety Laws. — These were strengthened in eight states. Pennsylvania, West Virginia and Wyoming, among other improvements, now permit rock dusting to be used instead of sprinkling for prevention of coal dust explosions. Oregon abolished her bureau of mines and transferred its functions to a board of supervisors serving without pay and representing the school of mines and mining interests of the state. New Jersey repealed its law controlling manufacture, storage and transportation of explosives and enacted one with stronger safety regulations. Congress finally authorized the printing of the report of the U. S. Coal Commission.

Safety regulations for compressed

air workers in New York were strengthened and in a dozen states minor improvements were made in sanitation or safety laws affecting workers in factories, restaurants, construction and transportation.

Old Age Pension.—Wisconsin became the fourth state to enact a noncontributory old age pension law. This law is elective by two-thirds vote of county boards, and is to be administered by county judges subject to approval of the state board of control. Recipients of pension must be seventy years of age, citizens of the United States and residents of the county for fifteen years immediately preceding application. Amount of pension, added to other income of recipient, is not to exceed one dollar a day. Nevada repealed its old age pension law and enacted another to be administered by counties. Alaska increased its biennial appropriation for old age pensions from $60,000 in 1923 to $110,000. The Pennsylvania legislature manifested its continued interest in the movement by the enactment of three measures. The first authorized the completion and printing of the report of the former commission, the second authorized the governor to appoint a new investigating commission and the third was a resolution, passed by both houses, to amend the constitution so as to permit the legislature to appropriate money for assistance of indigent poor. Eight states and the United States Congress passed amendments expanding improvements for retirement of public employees. Porto Rico repealed her law of 1923 and enacted one with less liberal provisions.

Mothers' Pensions.—The Sheppard-Towner federal maternity act was accepted by Rhode Island and Vermont, making forty-three states and Hawaii now coöperating. Wisconsin amended her mothers' pension law to provide aid to needy mothers for six months before and six months after birth of a child. Iowa and South Dakota improved their laws regulating maternity hospitals.

Minimum Wage Laws.—Court decisions rendering the minimum wage laws for women in Arkansas and Arizona invalid followed the precedent of the United States Supreme Court in the District of Columbia decision (1923). The Wisconsin minimum wage law, declared unconstitutional, in 1924, as applied to adults, was amended to require employers to pay reasonable and adequate compensation for services, instead of a living wage. The amount of such compensation is to be determined by the Industrial Commission which is also authorized to grant an employer a license to employ women at lower wage if he can prove that he is unable to pay that fixed by the commission, but his business inefficiency is not to be ground for granting such license. Wages of postal employees were increased by act of Congress.

Connecticut strengthened her women's hour law and provided that no woman or minor should be employed more than six days a week in public restaurants and certain other industries.

Agency Regulation.—Regulation of private employment agencies was established in North Carolina and strengthened in Michigan, Minnesota, Oregon, Wisconsin and Iowa. In Wisconsin the license fee is to be a certain percentage of placement fees and other charges received by the agency during the year. Appropriations for public employment bureaus were increased in Arkansas and New Hampshire. The industrial commission authorized by the new Arizona workmen's compensation law is empowered to maintain free employment agencies.

Miscellaneous.—The criminal syndicalism law of Idaho was amended by inserting a very drastic definition of sabotage. Illinois enacted a law, since upheld by court decision, forbidding injunctions against peaceful activity in relation to labor disputes, while New Jersey provided for jury trial of person disobeying injunctions in labor disputes. The Kansas industrial court was rendered practically powerless by decision of the U. S. Supreme Court in April, 1925. The Kansas legislature later repealed the law creating the court and conferred its functions upon the public utilities commission.

DIVISION XXVII

RELIGION AND RELIGIOUS ORGANIZATION

THE WORLD WAR AND THE CHURCHES

By H. K. Carroll

Corresponding Secretary, Asbury Memorial Association

Immediate Effect.—This has been world-wide on bodies Christian, Jewish, or Moslem, whether its work, its ideas and policies, the breadth of its activities, or the development of its resources in men and means is considered. It may be doubted whether it has left any of the religious unchanged. President Wilson's idea that the outcome should make democracy greater and safer in the world has evidently obtained in large degree, as the tumbling of thrones and the spread of Republican government bear witness. In the Christian Church its agency in relaxing the hold of doctrine appears not to be notable; other causes have entered into the modifications of its belief and particularly in its attitude with greater force, such as the rise of the newer school of scholarship, with its rationalistic interpretations of the Bible, which has from the beginning shaped the thinking and believing of Christian and Jew.

Service in the War.—The Churches of the United States stood in their accustomed place in the support of the nation's participation in the war, sending out chaplains, ministers, representatives of the Y. M. C. A., the Y. W. C. A., the Salvation Army, the Knights of Columbus, and other organizations to minister to the material, physical, social and intellectual needs of the soldier, as well as to his spiritual requirements; leaving many of the churches at home either pastorless, and without adequate plans of service or attention to church building and improvement, and its usual program of work. The loss in results was clearly indicated by the diminution of ingatherings of new members from the young and from the mature group, so that in 1919 the net additions fell to the lowest point in the history of a century, perhaps. Moreover, the immense contributions levied by the government for loans of unprecedented extent, impoverished the Church, which could not keep up its own financial demands in the urgency of the "drives" necessary to save the life of government and nation.

Post-War Period.—After the war, the people wanted a breathing spell and recuperation was naturally slow. Absorption in the material affairs of the men at the front, while it strengthened the widening activities of the Churches in the social service they had inaugurated before the war, brought under larger consideration certain cognate ministries along lines of broadening educational, recreational, and other human needs, including the building and endowment of hospitals, refuges, homes and orphanages, in which the Roman Catholic, the Lutheran, the Jewish and other denominations had long been preëminent among the denominations. At all events it must be said that the outcome of the war helped in securing the settlement of the question of social service and institutional churches for a line of work which few churches had previously entered upon, except hesitatingly and experimentally.

Denominational Peace. — Another

outcome of the war was the abatement of antagonisms and differences between the Churches. Humanity became the immediate concern of the church representatives in the theater of war, Catholic, Protestant and Jewish servants of the Most High not only touching shoulders in their benign service, but recognizing that they were upon the same holy errand, under commission of Him whom they all served and their denominational differences shrunk in the presence of suffering of wounded and dying. Some may speak sweepingly of the former fighting and bickering of militant Churches; but there never was as much of it in the narrowest times as many believed, and it has lost in these days its ruthlessness and its severity, and toward this desirable result the most bloody and cruel war in history has indirectly contributed.

Cessation of Sectarian Feeling.— Again, the pressure of the war caused the cessation of bitter sectarion feeling, but the recognition of the necessity for coöperation and unity. The peril was both national and international, the allied nations fighting together for life and liberty. With the same aims, fronting the same task and the same peril, the denominations must coöperate and engage unitedly in the work of defense. This conviction, while it had existed before the war, was stimulated and strengthened by the common service it inspired.

World Peace. — Another purpose which the war has drawn the Churches to advocate unitedly is that peace and the arts of peace must not be displaced by war, which is brutal, fatal and foolish; moreover, war is unnecessary, while reason is enthroned to find humane, effective, sane methods for the settlement of international disputes. Most of the denominations are agreed that armies and navies and airfleets are required chiefly for the policing of the nations, to control outlaws and criminals, and anarchists and to insure the enforcement of the laws for safeguarding civilization. If this steadfast conviction has drawn the denominations closer to political lines than some have hitherto been willing to go, it is another instance of how a great evil tends to unite religious forces in righteous demands upon a nation's rulers.

Moral Forces. — The unreserved recognition by President Coolidge of the important part which religion plays in its promotion of high moral standards, giving a force to law and effective government which no other power can impart, is evidently accepted by the Churches in general as a call to develop to the utmost their support of law enforcement and loyal obedience of its citizens in government operations. While the war did not bring religious coöperation and unity into being, it has greatly influenced and strengthened them.

INTERDENOMINATIONAL ACTIVITIES

The Federal Council of the Churches of Christ in America.— This body, representing some thirty of the evangelical bodies, indicates the breadth of its coöperative work by its Commissions on Social Service, Research and Education, Evangelism and Life Service, Race Relations, International Justice and Good Will, Relations with the Churches of Europe, Relations with the Western Churches, and coöperation in securing Army and Naval Chaplains. Its General Council meets once in four years, an Executive Committee, annually, and an Administrative Committee, monthly. Its declared purpose is to represent the "oneness of the Churches" in Christ and "to promote the spirit of fellowship, service and coöperation."

The Federal Council issued in the latter part of 1925 a carefully prepared review of the progress of enforcement of the laws under the Eighteenth Amendment to the Constitution of the United States. It was intended to be of a judicial character and it freely admitted that in many respects enforcement had been unsatisfactory and the churches needed to renew their former zeal in the work of educating the people as to the injurious effects of intoxicants. Its admissions as to the general disregard of the enforcement laws and warning that a serious struggle must take place before success could be secured, was a surprise to many and opinion was divided as to the wisdom of its publication. Most of the churches have organizations of their own to promote temperance and prohibition, and they also support the Anti-Saloon League in its active campaigns in the various states against any weakening of the Volstead Act, or any State legislation designed to break down prohibition.

The matter came up before the Executive Committee of the Federal Council at its meeting at Detroit, Mich., in December, 1925, and was fully discussed and freely criticized by the President of the Anti-Saloon League, among others, Bishop Nicholson, of Chicago, who said its admissions "put us back several years." The Business Committee, to which the matter was referred, reported that it was not expedient for the Council to enter the field of temperance and prohibition at this time.

Lay Organizations.—The Y. M. C. A. and its close second, the Y. W. C. A., with the Knights of Columbus, and other organizations, have greatly increased and broadened their activities since the War and carried them into all parts of the earth, even into Moslem countries. Millions of dollars have gone into their buildings, and their budgets are larger than ever before. Coöperative effort on religious lines has never before approached such large dimensions as now. The Jews, always at the top in beneficence, are raising $5,000,000 largely for the rehabilitation of Palestine, brought under their care by the outcome of the war.

The Y. M. C. A. Triennial Convention.—This organization held its session in Washington, D. C., in November, 1925. The most important item of business was the report of the committee on basis of membership appointed by the Convention of 1922. The report recommended the adoption of a new formulation as follows: "I hereby declare my faith in God, and my acceptance of Jesus Christ as Savior and Lord. I desire to serve him and to be his disciple in accordance with the teachings of the New Testament, and to unite with others in the extension of the Kingdom of God; and I am in full accord with the following purpose of the Young Men's Christian Associations of the United States and of Canada, and commit myself to its voluntary service and support: 'To lead young men to faith in God through Jesus Christ; to promote their growth into fullness of Christian character; to lead them into active membership in the church of their choice; and to make the extension of the Kingdom of God throughout the world the governing purpose of their lives.'" It was contended that this modification of the basis, which had been in effect since 1869, will secure more service from members than that of the past which required church membership. The new rule, it was said, for it was adopted, will raise the standard instead of lowering it. The Convention was attended by twelve hundred laymen and was addressed by President Coolidge, who said it was the greatest lay force in existence and was accomplishing a great work for young men.

Interest in Other Countries.—It is no longer possible to confine the interest of the Churches of the United States to their own country. Through the progress of foreign missionary endeavor in all lands, among all populations, Christian and non-Christian, Moslem and Pagan, the influence of the various cults on national and international affairs has immensely increased. This is illustrated by the position taken by such bodies as the Congregational National Council, the Episcopal General Convention, and the missionary societies of the Methodist, Presbyterian, and other Churches in notifying China in its struggle to obtain full national autonomy, that they will not ask for the continuance of extraterritorial privileges for their representatives, or any of the other special favors which suggest distrust of China's ability or willingness to guard the rights of aliens. Moreover, most denominations have come to admit that Chinese, Japanese, Hindu, and other converts who do not understand why there should be so many different denominations, all acknowledging allegiance to the same Lord, and so many variant polities, agree in asking that they shall have freedom in shaping their own organizations, and the autonomy of the nascent Native Churches in Asiatic, European, and South American countries has been forced upon the attention of the missionary organizations in the homeland and won their approval very generally. These, and other questions, have brought about changes not only in methods of conducting missions in foreign fields, but also in attitude toward the non-Christian masses and their religions, amounting almost to a revolution.

Protestant Foreign Mission Results.—A very considerable part of the activities of various American Churches and a rapidly growing contingent of missionaries, churches, and church members or communicants, are found in countries of other continents, not only among the great dense masses of populations of Asia, known as pagan, but also in Africa and in the islands of the sea, where the least developed form of religion, known as animism, also appears. Missions have long existed also in Latin America and in countries of Europe as well, whose indigenous faiths have long been Christian of various types. A *Missionary Atlas* appeared about a year ago, under the auspices of the Institute of Religious and Social Research of New York, with the coöperation and approval of the Foreign Missions Conference of North America and other organizations. It was edited by Prof. Harlan P. Beach, of New Haven, and Mr. Charles H. Fahs, of New York, and is the most thorough survey ever undertaken. It includes the work of the foreign missionary societies of other countries as well as those of the United States. There are 700 of these Protestant organizations (including those of women) of which nearly 400 send out missionaries, the rest being coöperative, raising funds, etc. The total annual income of the 700 societies reached in 1923, $69,555,148, of which about forty-five and a quarter million dollars was raised in the United States, $13,343,000 in Great Britain, $3,358,000 in Canada, $3,631,000 in the Continent of Europe, with Germany only represented in small part owing to the effects of the war. The grand total of over sixty-nine and a half millions indicates an increase of about forty-nine millions since 1900, and of sixty-five millions since 1859, sixty-six years ago.

The number of missionaries employed is 29,188 (including ordained men, physicians, teachers, etc.) of whom 17,744 are wives and single women. Besides this foreign force are 88,635 on the native staff. More than fifty per cent. of the missionaries are in Asia, over 55 per cent. the next larger number in Africa, 6,300, in Latin America 3,049, and in Australia, the Pacific Islands and elsewhere 1,810.

The Protestant constituency of communicants, baptized and under training, has increased from 3,613,391 in 1900 to 8,342,378, a gain of over 57 per cent., an average of 2.3 per cent. a year, which is beyond the annual Protestant increase of the Home Churches in the United States. It is an interesting fact that some of the large Protestant denominations in the United States have occasionally a larger net increase on the foreign fields than at home, with a working force many, many fold greater. This survey only covers Protestant missions, not Roman Catholic.

FINANCES OF 24 DENOMINATIONS

An interesting table has been prepared intended to indicate how large the financial budgets of twenty-four Protestant bodies in the United States were in 1924: for benevolences, for congregational expenses, and for all purposes, included in the two former budgets. The total for benevolences is $90,169,172; for congregational expenses $307,355,903: Grand total $453,277,266. The list embraces three Presbyterian Churches in the United States and Canada, three Methodist, three Lutheran, three Baptist, Congregational, Protestant Episcopal, Disciples of Christ, United Brethren and two Reformed bodies. All the larger churches are included. The returns for the Methodist Episcopal, the largest single body, are $96,514,193, including nearly $19,000,000 for benevolences and $74,307,000 for congregational expenses; the next in amount is the Presbyterian (Northern) nearly $57,000,000, of which $10,500,000 was for benevolences and over $40,000,000 for congregational expenses; the third, the Methodist Episcopal, South, $38,765,000, of which $3,389,207 for benevolences and the balance for other expenses; the Southern Baptists fourth, $34,533,132, of which $9,487,314 was for benevolences and $25,046,000 for congregational expenses; the fifth, the Protestant Episcopal, $37,459,000, of which $5,462,268 was for benevolences and $30,561,218 for congregational expenses; the sixth, the Northern Baptist, $32,689,000, of which $7,890,000 was for benevolences and $23,853,262 for congregational expenses.

The largest per capita giving for all purposes was by the United Presbyterian Church, $36.92; following in order, the Protestant Episcopal, $32.38; the Northern Presbyterian, $31.88; the (Southern) Presbyterian, $31.82; the Reformed Church in America, $31.55. The average of the Methodist Episcopal Church, with 3,895,434 members, was $24.78; of the Southern Baptist, with 3,494,189, was $9.88. The average for the 24 denominations with 21,909,675 members was $20.68. The foregoing figures were taken from a report prepared and issued by Harry S. Myers, Secretary of the United Stewardship Council, New York.

WORLD CHRISTIAN CONFERENCE ON LIFE AND WORK

This Conference was held in Stockholm, Sweden, in August, 1925, with Protestant Orthodox Eastern representatives present from forty-four countries, over 500 delegates from a hundred or more denominations, not including the Roman Catholic. Its purpose was to confer on such problems confronting the Christian Church as those of economy and industry, society and morals, international and interracial relations, a substitute for war, Christian education, coöperation and federation. There were from 1,200 to 1,500 persons present at the first session, including a strong representation from Germany, with President Hindenburg at its head, and patriarchs and prelates of the Eastern Orthodox, with their striking vestments and attentive retinues. The King and Queen of Sweden were in attendance and gave the Conference their royal support, the King pronouncing the welcome. The program was carried out under the appointed presidencies, the Bishop of Winchester, England, preaching the opening sermon.

The outcome of the Conference, not expressed in resolutions or official statements, seems to be first the fact that what is practically an Ecumenical conference, of Christians of all names and shades of belief, is possible, for it had been held, only the Roman Catholic Church being absent; that life and work are scarcely separable from faith and order; that the Church is not yet ready to advance beyond general principles in the discussion of economical and industrial questions; that Christians are ready for coöperation but not for unity. The message issued by the Conference has been summed up as follows: "The message is its own triumph. It is the charter of the world's salvation. It speaks of industry in terms of comradeship and coöperation. It construes property in terms of stewardship. It exalts personality above profits. It deprecates national bigotry and prays for a Christian internationalism."

South American Congress of Evangelical Churches.—The Evangelical Churches of the United States and Europe, which are conducting missionary operations among the Spanish and Portuguese population of South America, have been gradually drawing together in sympathetic coöperation, to make their work more effective; also as an economic measure and to avoid rivalry in the same territory. In accordance with this policy a Congress on Christian work in South America, not including that north of the Isthmus of Panama, was held in Montevideo, Uruguay, beginning March 20, 1925. Not only did the missionaries take part in it, but the representatives also of the native churches. The spirit of the Congress was not antagonistic to the Roman Catholic Church, which serves the majority of the people in each State and has the advantage in Colombia of being united with the State. There were about 300 delegates present, including 200 in South America and 100 from abroad, the latter consisting of officers of societies conducting missions in the southern continent. It was dominantly South American in its make-up, unlike its predecessors.

Commissions reported on various subjects and the findings had full discussions, in which the native members bore their fair part. The question of keeping Christian education definitely Christian evoked expressions not always in agreement as to method, but differing little as to the desirability of keeping the standard high. Evangelism was emphasized as of leading importance. The Indians received much attention and the difficulties encountered in this field of work were clearly set forth. The finding on this subject stressed the necessity of the Church agencies adding their efforts to those of the State in training the aborigines to become self-supporting and self-respecting citizens. There were four other findings devoted to the work among the Indians. The Evangelical Churches are said to be a part of the present indigenous life of the South American Republics and not foreign organizations standing outside of the life of the people. The Protestant Churches have 122,266 communicants, with over 2,000 ministers and other regular workers.

PROTESTANT ACTIVITIES AND CONTROVERSIES

By H. K. Carroll

Corresponding Secretary, Asbury Memorial Association

Modernist Controversy.—As this controversy affects a number of denominations, it will be more convenient to treat it apart from the year's history of the various bodies. It was not a movement which was started by the World War. On the contrary, the World War by interrupting communications between Germany and the United States, not only removed what had been an influential source of advanced biblical criticism, but made such literature as had come previously from German critics unacceptable. The influence of English views which have been for years quite in advance of American has been much more strongly felt on this side of the sea, not only in the United States but also in Canada. The Scottish school of criticism, of which Prof. William Robertson Smith, chief editor of the *Encyclopedia Britannica*, was a leader, spread quickly from the literary centre in Edinburgh through the Scottish Presbyterian and other churches, formerly quite conservative, and theological books of a liberal cast have been making their way for years to the United States. During most of the present century English and Scottish books have been affecting theological teaching in most of the seminaries, especially of liberal institutions, such as the Union (Presbyterian), and General Theological (Episcopal) seminaries in New York; Yale, in New Haven; Auburn (Presbyterian) in Auburn, New York; Methodist, Baptist and other schools; and books by a number of professors and ministers have been regarded by conservatives in the various denominations as constituting a sort of propaganda of liberal views on doctrines esteemed as fundamental.

The Issue.—The central question, perhaps, of the controversy, which seemed suddenly to break out a few years ago, and which came to the public knowledge chiefly by the daily press treating it somewhat sensationally, was as to the supernatural element in religion. Do or do not the discoveries of science forbid the holding that miracles such as the Bible recounts, could have actually taken place, including the virgin birth and the bodily resurrection of Christ? One of the most outspoken of the Modernists, who now prefer to be called Liberals, declared that he believed neither in "mysteries, miracles nor metaphysics," but did accept the conclusions of science as to facts. Underneath these questions as to doctrines set forth in the Apostles' and Nicene Creeds, in particular, was the matter of the view to be taken of the Scriptures. Were, for example, the statements of occurrences in the life and ministry of Christ to be accepted as facts, or were they to be treated as other history? The question of interpretation thus came into the controversy, with implications questioning the preëxistence and deity of Christ. The term Fundamentalist was probably first used by ministers and members of the Northern Baptist Convention, who at one of their annual conventions had a separate gathering where they set forth the points upon which they were agreed as a positive statement of belief. One of their leaders afterward entered into a series of debates with a Unitarian minister, in New York. The controversy spread to other denominations and several Episcopal rectors declared themselves as Liberals.

The occupant of a Presbyterian pulpit in New York, a Baptist serving as a supply, discussed the questions involved in a moderate, winsome way and gained many adherents. This raised the question as to whether the Presbyterian Church could tolerate statements opposed to its doctrinal standards, and the New York Presbytery was required by the General Assembly to deal with it and also received directions from the General Assembly to exercise care in admitting men to ordination. The outcome was action by the General Assembly of 1924, which led Dr. Fosdick to vacate the pulpit of the Third Presbyterian Church in New York. At the same time the General Assembly, under the moderatorship of Dr. MacCartney, and the leadership of Hon. William J. Bryan, took action which placed the new views under ban, against the protest of a large minority that it was unconstitutional and infringed the rights and liberties of its ministers. In 1925, the General Assembly in several cases declared that presbyteries could not lawfully license preachers who cannot aver their belief in the virgin birth, and it also ordered the appointment of a committee of fifteen to inquire as to the causes of spiritual unrest in the Church and to make report to the next Assembly, to the end that purity, peace, progress and unity may be assured.

In most other churches these matters have not become open issues, either because of the spirit of toleration, or because they have not become a question of challenge. The trial at Dayton, Tenn., of a public-school teacher accused of teaching a doctrine opposed to the Scriptures—evolution—brought the theories of science under wide discussion, in which the wisdom of the attitude of the State was very generally questioned.

INTERDENOMINATIONAL UNIONS

Unification Among the Churches.—The tendency toward reunion among several groups of Churches bearing the same denominational names, as Baptist, Methodist, Presbyterian, Lutheran, etc., is one of the notable signs of progress in the present century. The Federal Council of the Churches of Christ in America shows the strong sentiment for coöperation existing in the United States and England, where a similar body of free churches exists. But actual reunion in various groups has taken place in recent years.

United Church of Canada.—The consolidation of three distinct bodies in Canada took place in Toronto in June, 1925, viz., the Presbyterian, Methodist and Congregational Churches. Previously, various bodies of Presbyterians and of Methodists had created one Methodist and one Presbyterian Church. Union of the three bodies was long pending, delayed by an attempt among the Presbyterians to reduce an opposing minority to the smallest number and by the World War. Finally the plan of union was submitted to the votes of the general bodies, of the presbyteries, conferences and associations, and of the local churches. The returns were deemed to justify consolidation and consolidation was accomplished enthusiastically in General Council representing the three bodies, which elected officers to serve during the interim. The lapse of six months shows that all the local churches of the Congregational and Methodist bodies are in the union; but of the Presbyterian local churches, 700 remain outside and continue in a separate organization.

The name of the new body is the United Church of Canada, the first in the history of Christianity to be formed from such different denominational elements. It unites a basis of doctrine of twenty articles of a modern cast, and its polity is presbyterial, embracing a General Council, presbyteries and conferences, the latter occupying the place of synods and embracing presbyteries. Missions, home and foreign, and other societies engaged in church work are to be consolidated into one organization for each kind of work, in place of the three denominational organizations.

The first President of the Church is a Presbyterian, Rev. Dr. George C. Pidgeon, and the first secretary, a Methodist, Rev. Dr. A. T. Moore.

The question has arisen as to the interdenominational relations of the new body. The Methodist Church was a member of the Ecumenical Methodist Conference, a decennial body, including Methodist bodies throughout the world, and as such, had a place also on the Ecumenical Methodist Commission for America, Canada and Japan. The United Church has been recognized by the Eastern Commission, with headquarters in England, which action will doubtless be followed by the Western Section when the Commission meets. The United Church has also been accepted as a Presbyterian Church by the Council of the World Union of the Presbyterian and Reformed Churches. The Congregational element does not lose its identity with other Congregational bodies. Therefore, it seems to be settled that the merging of the three denominations in one does not affect its former triple alliances.

Consolidation of Lutheran Bodies.—In 1918 the most notable union ever planned and carried out took place in the Lutheran group, viz., the General Synod, the oldest organization, the General Council and the United Synod South, three large general bodies, with subordinate synods.

The organizing conference was held in New York, in 1918, and did its work in the utmost harmony, adopting the name, the United Lutheran Church in America, upon the basis of the old Lutheran standards of doctrine—the Augsburg Confession, the Formular Concord, etc. In the years following, union of contiguous local churches, of synods, and of missionary and benevolent societies has been proceeding, and the United Church has prosecuted its work at home and abroad with increasing force and efficiency. One of the largest Lutheran bodies, with headquarters in New York, it has exerted a large influence at home and abroad. It has become the center of a Lutheran National Council, organized during the World War to prosecute American Lutheran interests at home and abroad. It was preceded by the union of three Norwegian Lutheran bodies as the United Norwegian Lutheran Church of America, reducing the number of Lutheran bodies by four.

Union of Two Sister Bodies in Evangelical Church. — Two bodies known as the Evangelical Association and the United Evangelical Church, which had divided in the last quarter of the nineteenth century, came together a few years ago as the Evangelical Church, a Methodist Body, organized early in the nineteenth century by a ministerial friend of Bishop Asbury named Albright.

Foreign Mission Unions.—Unification of the Congregational, Presbyterian and United Brethren Churches, created in the Philippine Islands by their respective Missionary Boards in the United States, has taken place. There are now such unions in Japan, embracing Methodist bodies in one, and Congregational and Presbyterian in another; United Church in South China; United Church of South India; United Church of North India, making with the Philippine Union, six in the great mission fields.

Proposed Unification of Methodists. — Plans of union have been proposed, amended and rejected by the two leading Methodist bodies, viz.: the Methodist Episcopal Church and the Methodist Episcopal Church, South; during the present century. They were considered as unwieldy or unworkable, or as creating divisions into zones, with undesirable additions of conference machinery, and so were laid on the shelf. Finally, a very simple plan was proposed, which to some seemed only a sort of federation, but to a majority was a workable proposition, which would gradually accomplish consolidation. It was submitted to the Northern General Conference at Springfield, Mass., in May, 1924, and adopted by an overwhelming vote. It was sent down to the annual conferences for constitutional affirmation, and was adopted (1925) by far more than the necessary two-thirds vote of ministers and laymen. It was submitted in July, 1925, to a special session of the General Conference of the Methodist Episcopal Church, South, and adopted by a two-thirds vote. It was sent down to the annual conferences, in the constitutional process, and received, 1925, a majority, but not the required three-fourths vote. It therefore fails.

The two bodies would have made a united church of about 7,500,000 members, and healed a long-standing division created in 1844 by differences on the slavery question. The failure in the Church, South, may be attributed to several causes, first, fear of strong conservatism that modernism has too firm a hold in the Northern Church; second, lack of personal knowledge of northern men by the leaders and ministers of the south, and third, influence of the caste question among the older generation of the South. Two Negro bishops and a large contingent of Negro ministers and members in the Northern Church made the old objection to intermingling of the races a real obstacle to the closer relation.

Proposal to Unite Orthodox and Evangelical Christian Bodies.—This was launched by the Episcopal General Convention of 1910. (See American Year Book, 1919, pp. 746-7.) Acceptances from Anglican, Eastern Orthodox and many Protestant bodies were received and subjects for discussion between denominational groups, relating to the ministry, doctrine, sacraments and the like were issued.

Among others such discussions were held between representatives of the Established Church of England and the Union of Free Churches there. These, it is stated, have been abandoned (1925) at the intimation of the Anglican bishops that there is little hope of agreement on the Historic Episcopacy, one of the points of the famous quadrilateral statement issued by the Lambeth Council some years ago. This failure was not in relations introduced by the Protestant Episcopal Plan of 1910. Announcements of the meeting of the proposed world council in Washington, D. C., at different dates have been withdrawn; but the Continuation Committee having the matter in hand, announced in August, 1925, the holding of the Conference in the year 1927, leaving exact date and place to be named in the future. The subjects for discussion, meantime, in interdenominational groups are: The Call to Unity, the Nature of the Church, the Common Confession, the Ministry, the Sacraments, the Unity of Christendom, Continuation of the work of the Conference. As the Conference might not be in session long enough to complete consideration of all these subjects, the Committee suggests that topics five and six might be dropped.

ACTIONS OF DENOMINATIONAL BODIES

By H. K. Carroll

Corresponding Secretary, Asbury Memorial Association

BAPTIST BODIES

Northern Baptist Convention.—Its session in 1925 was held in Seattle, Washington, beginning in June. President Carl E. Milliken in his address proposed a referendum of all vital questions to the local, as a new idea in Baptist procedure. Then followed in long succession the reports of missionary and other societies, including those of women. For the Foreign Missionary Board it was stated that unless the churches keep their promises more faithfully than in the past year or two, much work must of necessity be abandoned. The reason for this statement was shown in the report of the Finance Committee, indicating that the total receipts for the year had reached $5,000,000, whereas $6,700,000 had been expected.

The question was raised as to whether four delegates from Park Avenue Baptist Church, New York, including the pastor, Dr. Woelfkin, should be received, as it appeared that the Church had voted not to require immersion as the only form of valid baptism in the reception of members under the coming pastorate of Dr. Fosdick. Sharp discussion took place, but the report of the Committee on Credentials to the effect that the election of the delegates appeared to have been regular was adopted by a large majority.

For some years reports had been current that missionaries had been sent to the foreign fields who were not sound in the fundamentals of the faith. A committee to investigate and report had been appointed by the Convention of 1924. This report stated that it found no evidence that missionaries of liberal type had been appointed by the secretaries, or that others had been refused because they were conservative. On the contrary, some had been rejected because they were liberal and none because they were conservative.

The Convention, after full discussion, adopted resolutions expressing pleasure at the assurance that the missionaries are working in harmony with Baptist faith and Baptist principles, and urging due care upon the Board in conserving the interests of the truth. Edwin H. Rhoades, Jr., of Ohio, was elected President for the ensuing year.

The Baptist Bible Union.—This organization for missionary work on a definite doctrinal basis in harmony with the Fundamentalist movement came into existence at a meeting in Chicago, in November, 1925. The Union is not new. It was formed in 1850 for the purpose of securing and publishing a version of the Old and New Testament conforming to the original text in the matter of the translation of the Greek *baptizein* by the English word immersion. The preparation of this version has been proceeding under the auspices of the American Baptist Publication Society, to which the work was referred in 1882. The Bible Union was originally a secession from the American and Foreign Bible Society (Baptist) formed in 1836 as a protest against the American Bible Society's continued publication of versions with the old translation of *baptizein.* The two former bodies reunited in 1882. The Chicago session was attended chiefly by ministers and members of the Northern Baptist Convention.

After the consideration of a program relating chiefly to the Holy Spirit's work, the convention organized a missionary department for home and foreign operations within the lines of the Union's confession of faith, which is conservative. No missionaries are to be employed except those who are in harmony with the Union's creed. Churches coöperating in the missionary enterprise are not required to separate from their present affiliations, and missionaries may continue to hold their present denominational relations. But the missions are to be established without regard to those conducted by the Northern Convention or other Baptist bodies. The new movement is regarded as a protest against modernism.

National Baptist Conventions.—In the past half dozen years or more the Negro migration from the South to Northern cities, like St. Louis, Kansas City, Chicago, Philadelphia and New York, has brought about an apparent decrease of 150,000 or more in the membership of the two Conventions.

This apparent decrease is due to the fact that the masses who have left the South have not found sufficient Baptist Church accommodations in the cities to which they have removed, and so many attend other churches or none at all. The migration is assigned to various causes, including complaints that their franchise is denied them, that a system of employment has arisen which reduces their freedom, and that wages are much higher and conditions of life much more attractive in the North. Other Negro bodies likewise suffer loss from this migration.

CONGREGATIONAL CHURCHES

National Council.—This body held its biennial Council in Washington, D. C., in October, 1925. It has been represented by a national organization only since 1865, which has no ecclesiastical power over local churches or State bodies, but exercises administrative direction over its missionary and other denominational societies and expresses the mind of the membership on general questions. The President of the United States, who became a member of the First Church, Washington, some months previously, presided at its first meeting as honorary moderator and made a notable address. Mr. and Mrs. Coolidge entertained a number of the delegates at the White House, during the ten days covered by the Council. Delegates chosen by State organizations were present from many States, including ministers and laymen, with elect ladies, and many attendants.

Reorganization.—The more impo tant subjects considered by the Cou cil were brought before it by Commissions appointed previously wh presented fully considered report with recommendations for discussio and action. First in importance, pe haps, was that of the Committee twelve on "Unification and Organization." It recommended that the fo eign work covering the conduct missions in foreign lands, administration at home, appeals to the churche educational and promotive work should be under the American Boar the oldest body of the kind in Ame ica, with which the Women's Board should be unified, providing for Presidential Committee of thirty-si one-third of whom shall be women also departmental secretaries, a cab net composed of these, and certai other commissions.

In the home work various societie are to be unified in a Congregationa Home Board, with the ultimate hop that all shall become a corporat body, under that name. There ar eight such societies—two missionary a church building, a Sunday Schoo a publishing, two educational and ministerial relief organization. Provision is made for two women's societies in the consolidation, which i to be worked out gradually. A boar of 36 directors, one-third women, i to carry on the work of these various societies, serving each. Provisions for its guidance are given i detail. Suggestions are also offere for acceptance concerning the relations of representatives of State organizations with the General Council and recommendations as to consolidation deal with the three periodical publications of the denomination, *The Congregationalist*, *The American Missionary* and *The Missionary Herald.*

Commissions and Boards.—The Commissions on Social Relations and on Interracial Relations presented reports which took a forward look and laid down principles which they hoped might come more and more to be accepted as sound bases of coöperation. They hold that the ideals of Jesus must become the test of community as well as of individual life, applying to education, industry, agriculture, interracial and international relations. They oppose the cutting down of working hours below eight. One report called for the abolition of military armaments, except for internal police. In a resolution on conflicts between science, scholarship and religion, the Council declared that there is not and cannot be any conflict between religion and science and deplored any State or Federal attempt to interfere with teaching of any widely accepted scientific theories.

The resignation of Prof. Edward C. Moore, who for many years has served, first as chairman of the Prudential Committee and then as President of the American Board, organizations which are as old as the modern missionary movement, was received.

An old and troublesome controversy was brought to remembrance in 1925 by decision of a Massachusetts Court that Andover Theological Seminary could not, under its trust obligations, unite with the theological department of Harvard University.

Proposed Union with Universalists.—The Council received memorials from two of its State bodies dealing with a proposal of a union of Congregationalists and Universalists and voted to appoint a Commission to consider the subject, with a similar commission from the Universalist Convention, the Council on its own part welcoming into "its fellowship all churches which can find freedom and satisfaction on the general basis of the Kansas City declaration in 1913." This was a statement in non-theological terms of recognition of the fatherhood of God, the sonship and lordship of Christ, the Savior, and the revealing, renewing and comforting power of the Holy Spirit. It holds to the Gospel for all mankind, and promises to work and pray for "the transformation of the world into the Kingdom of God." The Universalist denomination was an outgrowth of sentiment created in the Congregational, and a few other bodies, in the controversies that rose a century or more ago against certain Calvinistic doctrines, especially that of the eternal punishment of the finally impenitent, and dates from the beginning of the nineteenth century. The Unitarians, also an offspring of Congregationalists, approached the Universalist General Convention held in Syracuse, in October, 1925, and invited that body to appoint a commission to meet a similar one from the Unitarian Conference to organize "a council of representative liberal Christians for the purpose of promoting sympathy and coöperation and furthering their common aims and uniting them for the advancement of the Kingdom of God." Some cherish the hope that these commissions may draw all liberals closer together.

Resolutions. — Among the resolutions adopted were these: on religion and science, reaffirming loyalty to the old but welcoming all new light, and recognizing the demand to preach a gospel consistent with modern scholarship; accepting opportunities to exhibit the spirit of Christ in interracial concerns; declaring sympathy with China's desire for absolute sovereignty, and disclaiming "special privileges for our missionaries," asserting that it is the duty of Christian people to find a peaceable way of settling international difficulties and avoiding war.

The Disciples of Christ.—Their annual convention at Oklahoma City, in October, 1925, passed in review their missionary and benevolent work for the year, and other denominational concerns, including educational institutions with which they are well provided.

EASTERN ORTHODOX BODIES

American Conference. — The Federal Council of the Churches of Christ in America has appointed a special committee, with Bishop Charles H. Brent, of the Protestant Episcopal Church, at its head, to plan a conference between representatives of the Eastern Orthodox Churches and American Churches, somewhere in Europe, to discuss social, educational, and international questions.

Russian Orthodox Church in America.—For many years this body, the largest of the Eastern Orthodox

Churches, has been represented in the United States, first in Alaska when it was Russian territory, and on the Pacific Coast and then in the Eastern States. In New York, where there is a large population of Russians, it has long possessed a cathedral and a resident Archbishop. Since the Bolshevist revolution in Russia there have arisen differences over the possession of the property and government centering in the cathedral. Three claimants have been contending in the State courts for possession. In November, 1925, the appellate division of the New York Supreme Court gave a decision in favor of Most Rev. John S. Kedrovsky as the lawful archbishop, ruling against Archbishop Platon, who had the recognition of Tikhon, head of the Church in Russia. The case was complicated by the action of a Convention in Detroit, Mich., in 1924, which the court holds was in effect a secession, whose appointment of one Rodesvensky as American Archbishop was null and void, and that legality belongs to Kedrovsky, whose appointment was made by the "Holy Synod" in Russia. Meantime Patriarch Tikhon, of Moscow, is dead, and the "Living Church," a new organization recognized by the Soviet, appears to be declining in power. It had promise of support from bishops of the Methodist Episcopal Church resident in Europe for a Theological Seminary, but the approval of the Methodist Board of Bishops, at first granted, was subsequently withdrawn.

All-Russian Evangelical Union.—Various American bodies of Baptists, Methodists, etc., have been carrying on, with resident Lutherans, who have large numbers of native members, protestant missionary work, and have organized an evangelical federation, of which I. S. Prokhanoff is President. It is known as the "All-Russian Evangelical Union," and, according to Mr. Prokhanoff (who has been in the United States recently) under "the toleration policy" of the Soviet, has complete religious liberty. But Bishop Boaz, of the Methodist Episcopal Church, South, reports the Sunday School work of that body among children below eighteen, suffers much interference by th Soviet, which claims control of th education of children. The Union ha nine churches in Leningrad, and fiv in Moscow. In some places they us the vacant buildings of the disestab lished Church. Peasants, industria workers and laborers in general ar flocking to the new organization.

Czechoslovakian Churches. — Thi new Republic, the outcome of th World War, has representation o its Protestant elements in the Unite States, a church of its people havin been organized in Newark, N. J. last fall. The revolution by whic the new nation and government wa created is reported by Presiden Masaryk to have brought up the ref ormation ideas, as represented by th Hussite or Reformed, and the Augs burg or Lutheran elements. Thes have greatly increased in the pas five years, while the Roman Catholi body, with its uniate, or Greek ap pendage, has apparently decreased The Orthodox or Eastern Church akin to the bodies having Patriarch in Constantinople, Greece and else where, has also been strengthened. I all the provinces complete religiou liberty prevails, though in some o them there was little or no tolera tion before the war.

LATTER DAY SAINTS

Utah Branch.—There are two o these bodies, otherwise known a Mormons adhering to the Book o Mormon, said to have been given orig inally as a divine revelation. Th older branch is distinguished as th Utah Branch. It removed from Illi nois to Utah. There the Church o Jesus Christ of Latter-Day Saints has its central organization, in Sal Lake City, its Tabernacle and Tem ple, and its chief officers. The popu lation of the State generally adheres to it and it has many belonging to i in adjoining States. Its annual con ference is held in the month of April in the Tabernacle, a large oval build ing of fine acoustic properties. The 95th conference in 1925 was attended by: the first (dual) presidency, He ber J. Grant and Anthony W. Ivins the Council of Twelve; the presiding patriarch, Hyrum G. Smith; members of the Council of Seventy, of the Presiding Bishopric and other officers; with presidents of the ninety-four stakes, or districts, into which the Church is divided, and many missionaries and others.

The financial report showed that the tithe system had yielded for the year very nearly four million dollars, besides $489,406 from other sources. Of the tithes, $1,352,663 went for stake and ward purposes (wards are subordinate parts of stakes); $727,-809 for church schools; $175,521 for care of the worthy poor; $442,000 for construction and maintenance of temples or churches; and $700,664 for missionary operations, etc. It appeared that during the year 19,955 children had been blessed and thus made members and 14,047 baptized. The converts of the year numbered 7,556.

Among the reports was one on marriages, births and deaths, from which it appears that 33 per thousand is the birth rate; 13 per thousand the marriage rate, and 7.3 per thousand the death rate. There are 160,634 persons in the Church who are married, and there were 256 persons divorced during the year. The missionary work in this country, Canada and Mexico, has nearly 1,100 missionaries, 64,189 members and church property valued at somewhat over a million dollars. There are in Europe (Continental) 561 missionaries and 32,205 members, in England 151 missionaries and 5,670 members. There are also missionaries of the Latter Day Saints in Australia and the Pacific Islands. The mission which existed in Japan has been discontinued.

Reorganized Latter-Day Saints.—This body has its headquarters in Lamoni, Iowa. It owns Joseph Smith as its organizer, but rejected from its beginning the Revelation under Brigham Young that authorized polygamy. It has a great number in its ministerial ranks in proportion to its members. It accepts the Bible, the Book of Mormon and the Book of Covenants, which contains the revelations to its own leaders.

LUTHERAN BODIES

By H. K. Carroll

Corresponding Secretary, Asbury Memorial Association

Unions.—The chief event among the American Lutheran bodies since the World War—union of three Norwegian bodies in the Norwegian Lutheran Church and of three large general bodies in one, the United Lutheran in America has brought all Lutheran bodies into closer relations. There are no confessional divisions among the eighteen separate bodies, most of which are not large, and all of which are working for common objects coöperatively through the National Lutheran Council.

Yet, though Lutherans have not been drawn into the Modernist controversy, the ministry and membership, according to President Boe, of St. Olaf College in Minnesota, are feeling to some extent the influence of liberalism and confessional faith is being undermined to a degree that should call for attention, especially in Europe where the Church is subject to strong nationalistic influences.

The United Lutheran Church.—In the seven years of its existence it has developed no divisive differences, but is by the process of merging synods occupying the same territory or parts of the same territory, taking a long step forward economically and intensifying its strength in fellowship and coöperation. During 1925 three Lutheran synods, occupying territory in New York and New England, made progress toward union, including the synod of New York, the synod of New York and New England and the ministerium of New York, the three representing over 133,000 members. The United Lutheran Church has taken forward steps in the last two years for the occupation of a large new field in China, the establishment of

Andhra College in India, the founding of a Woman's College in the United States, making mountain work a part of the Church's program, planning larger provisions for immigrants arriving at New York, beginning a work at home among the Spanish speaking, etc. The two largest independent synods, the Ohio, with 148,000 members, and the Iowa, with upward of 137,000, are voting on a proposition to merge. Most of the districts of each have voted favorably.

National Lutheran Council of America.—Representatives from the United States met various European representatives at The Hague, in 1925, at Amsterdam and elsewhere. At Amsterdam it was reported that $20,000 had been given in eight months of 1925 for the help of Lutherans in Russia, for impoverished families in Siberia, and for the theological seminary in Leningrad, and that $50,000 more was being raised. The Soviet Government has recognized the organization of the Lutherans of Russia, who are very numerous, especially in Finland. Three synods of Finns exist in the United States and Canada. It was decided that a second World Lutheran Conference should be held in 1929, on the 400th anniversary of Luther's smaller catechism, which has done so much for the religious education of Lutheran youth in religion. Provision will be made for the observance in 1930 of the 400th anniversary of the Augsburg Confession, the universal symbol of Lutheran doctrine.

Aiding Foreign Missionary Societies in Germany. — Part of the work of the American Lutheran Council has been to help care for the foreign missions conducted in India, Africa, and other countries by the Lutherans of Germany, which were necessarily suspended during the world war. The Leipzig Society was only able to resume its wor
India in 1925. Some of the missi
in Africa, for example, were al
ated by government action and tr
ferred to other societies. In 1
American Lutherans gave $25,00
help the Gossner autonomous L
eran Church in India, with an a
tional $3,000 in answer to a spe
appeal.

THE METHODIST BODIES

By H. K. Carroll

Corresponding Secretary, Asbury Memorial Association

METHODIST EPISCOPAL

Plans of Union.—The event of greatest interest in 1925 to both this Church and its sister Church, the Methodist Episcopal, South, was the voting of the annual conferences of each, at home and abroad, on the question of changing their constitutions so as to allow their merging to be made effective. The conference of the former body gave a total vote of both ministers and laymen which not only met the two-thirds required, but went far beyond. The opposition to the motion in question was very small. The vote of the annual conferences of the Southern body gave an actual majority of ministers and laymen for unification, which, however, came several hundred votes short of the requisite three-fourths required.

Centenary Appeal.—In 1919 a centenary movement was launched in the Methodist Episcopal Church for a memorial to take the form of a great advance in financial support of the two boards of missions, into which the original Society had been divided, and of the other benevolent organizations.

This campaign was conducted most vigorously and with large results, the first year yielding a total sum far beyond anything the Church had ever expected or dreamed of. The result was that the Boards of Foreign and Home Missions and other benevolent societies increased their respective enterprises to an unprecedented extent. The force of the movement, when its success was demonstrated, was gradually lessened by the "drives" started for increase of endowments of educational and other institutions, and the Church lagged year by year under the pressure of the unprecedented demands, creating discouragement where enthusiasm had prevailed, so that the returns of the fifth and last year had diminished to $11,865,000. At the end of the period, the strong staff which each episcopal area had created to push the centenary appeal, was reduced or abandoned and the World Service Commission came into control with central offices in Chicago. Under its management the annual income gradually decreased from $11,865,000 to $7,631,000 in 1925, not that the management was inadequate, but because the constant pressure had decreased enthusiasm, the drop in that year being beyond a million.

Interchurch World Movement.—In the midst of the five-year campaign a movement was formed by various denominational missionary and other societies, known as the Interchurch World Movement, the governing idea of which was that under united direction and concerted appeal, the incomes of all the societies could be raised together. The scale of operations was necessarily a large and costly one, and the expenses were so great and the results of the public appeal so much less than the expectation, that the movement was crushed with heavy debts. The larger societies had under-written the cost, that of the Methodist Episcopal being considerably beyond a million, which had to be met and carried as a debt, with nearly a million more, which the Columbus (Ohio) Centenary Exhibition had involved, over and above its receipts.

This total debt has reduced the work of the Board of Foreign Missions and of the other societies, and with falling incomes has created embarrassment. The Board of Home Missions lost about $200,000 in the Interchurch World Movement, and other societies lesser amounts.

Skyscraper Churches. — In the changes that go on in cities in the movement from "down-town" to "up-town" of the population, in many cases masses of people have been left in the down-town section without church accommodations. To meet the condition where business has created density, a new system has been devised by which "sky-scrapers" have been erected in centers where business accommodations occupy most of the building, leaving the upper portions to church occupation. One such building has been erected in Chicago, and another has been planned for New York, to be known as the Broadway Methodist Temple. It will be a development of the Chelsea Methodist Church, which, in its present location, is working in a roofed-over basement. It is to occupy the block on upper Broadway between 173rd and 174th Streets, and is to cost about $4,000,000. It provides for a church seating 2,200 with all necessary equipment, for an apartment hotel, for housekeeping apartments and for stores, the rental of which is to provide the necessary income for taxes, expenses, interest, etc., leaving $125,000 annual surplus to retire the bonds which have been secured to finance the erection.

A similar Baptist enterprise is to provide a new church for Dr. Fosdick, who has assumed the pastorate of the old Fifth Avenue Baptist Church.

METHODIST EPISCOPAL, SOUTH

A special meeting of the General Conference of this body was held in Nashville, Tenn., in July, 1925, to take action on the basis of union which had been adopted by a Joint Commission of the two bodies. After a sharp discussion the basis was approved by a two-thirds vote. A campaign was conducted in the Church thereafter, which showed a divided opinion. The voting in the annual conferences indicated that the foreign conferences were almost without exception for the union, and an affirmative sentiment preponderated in the conferences in the border states, including those in the west and on the Pacific, in Missouri and elsewhere, but the conferences in the old South voted quite heavily in the negative, so that the affirmative votes of the Church as a whole reached a majority, but fell many short of the necessary three-fourths. The actual voting was as follows: for union, 4,52
against, 4,108; majority for, 420.
three-fourths was necessary the v
ing fell short by 1,949 of the cons
tutional number. This body a
made a centenary appeal in celeb
tion of the centenary of the Missio
ary Society, which had served bo
Churches until the separation of 18
46. The results to the missiona
and benevolent societies of the Sou
ern Church were proportionate
large, enabling an advance to be ma
in all its work. Since the centena
the annual income has been decrea
ing proportionately to that of t
Northern Boards, and a large defi
was reported in 1925.

Colored Bodies.—There are vario
other Methodist bodies, includi
three large and several smaller bodi
of Negroes, who, affected in the Sou
by the migration North, are increa
ing their accommodation in Ne
York, Philadelphia, Chicago, a
other centers, by the erection of cost
and commodious buildings. T
larger bodies are the African Meth
dist Episcopal, the African Methodi
Episcopal Zion, dating from the b
ginning of the last century, and t
Colored Methodist Episcopal Churc
being the colored constituency of t
Southern Methodist Church, whic
after the Civil War, the latter orga
ized into a separate body. The
three bodies have agreed amo
themselves on a basis of unio
The outcome is not at present pro
ising.

Another large body of Negro Meth
dists exists in the form of separa
annual conferences in the Methodi
Episcopal Church, having two bisho
to supervise them. This body ha
a few years ago, about 360,000 mem
bers, but the Negro migration to th
North has decimated some of its co
ferences. The presence of these N
groes in the Methodist Episcopa
Church, where they have full righ
in the General Conference, and th
fact that their bishops, though electe
to serve Colored Conferences, hav
equal powers and dignities with whit
bishops, undoubtedly had a large in
fluence in defeating unification be
tween the Northern and Souther
Churches.

PRESBYTERIAN BODIES

By H. K. Carroll

Corresponding Secretary, Asbury Memorial Association

Presbyterian World Alliance.—The various Presbyterian Churches of the United States and Canada, of Great Britain and Ireland, Australasia and other countries, including also the Reformed Churches which were a part of the Reformation by Martin Luther, are members of an organization known as the Alliance of Reformed Churches throughout the World, Holding the Presbyterian System, the twelfth General Council of which was held in Cardiff, Wales, beginning June 23, 1925. This body meets once in four years. The Alliance consists of two sections, a Western, including the United States and Canada, and an Eastern, including the British Isles and other countries. The Council of the Western section was held in Richmond, Va., in February, 1925. It considered a report on Home Missions and restated existing rules on comity designed to prevent overlapping of work in the same territory, to group weak churches which cannot stand alone, and in communities of 5,000 people or less, where one church already exists, not to establish other churches. A committee to allocate fields and programs for coöperative work was named. Similar measures of comity and coöperation are being carried on and extended in foreign missions.

In the summer of 1925, Presbyterian and Congregational Churches in India surrendered their own distinctive names and organizations and formed the United Church of India. It is announced that the two general bodies in the United States and Canada, known respectively as the Western section of the Alliance and the General Council, are to be united under the control of the Alliance as soon as proper arrangements can be completed.

PRESBYTERIAN CHURCH IN THE UNITED STATES OF AMERICA (NORTHERN)

Controversies in New York.—In recent years this body has been disturbed by the Modernist controversy, both sides having representatives in the General Assembly and in certain presbyteries, of Fundamentalism and Modernism, or Liberalism, as it is now called. Acts of the New York Presbytery have been chiefly objected to in the General Assembly of 1925, 1924 and 1923. The decisions of this supreme judicatory in these years have been directed in the main to two matters, the ordination of young ministers, generally graduates of Union Theological Seminary, Liberal, formerly a Presbyterian institution under oversight of the Assembly, but now not officially related thereto. Some of these candidates either declared they did not accept the Virgin birth, or that they were not settled in mind on it. The other question was as to the continued relation of Dr. Harry Emerson Fosdick, a Baptist minister, serving as supply in the pulpit of the First Presbyterian Church, New York, whose preaching seemed definitely Modernist or Liberal on various doctrines of the Apostles' and Nicene Creeds, including that of the Virgin birth.

Fosdick Case.—The action of the General Assembly in 1924-1925 brought both of these issues to a conclusion, upon reports of the Permanent Judicial Commission, with the General Assembly sitting in its capacity of Judicial Court. The Presbytery communicated to Dr. Fosdick the requirement of the General Assembly of 1924 that he accept the Presbyterian standards, assume the theological vows in the terms of the Westminster Confession, as other pastors who serve regular Presbyterian Churches are required to do.

Dr. Fosdick made answer to this that it had long been his conviction that subscription to ancient confessions of faith is a practice "dangerous to the welfare of the Church and to the integrity of the individual conscience." The outcome was the severance of his relations with the First Church, March 1, 1925.

Licensing Candidates.—The decision of the General Assembly as to the licensing of candidates who declared they could not either affirm or deny belief in the Virgin birth was to the effect that the licensures should have been delayed or refused as, according to the Constitution of the Church, belief in this doctrine is the established law of the Church. Therefore, the position of the presbytery and also of the Synod of New York was disapproved.

Committee on Spiritual Condition.—The Moderator of the Assembly, Prof. Charles R. Erdman, was authorized to appoint a committee of fifteen "to study the present spiritual condition of our Church and the causes making for unrest" and to report to the Assembly of 1926, "to the end that the purity, peace, unity, and progress of the Church may be assured." The Committee held its first meeting in Atlantic City, N. J., in December, 1925, and heard representatives, behind closed doors, of the Fundamentalists and the Modernists, or the Liberals as they have preferred to be called.

Church Finances. — The General Council which is practically an executive committee of the General Assembly *ad interim*, at a meeting in December, 1925, adopted a plan of financial management for the Church in accordance with modern methods of business. It provides for a Secretary of Finance who will have a three-year term of office. The four Boards of the Church asked for a total budget for next year of $18,093,222, which does not include running expenses of churches, salaries of pastors, etc. The Council adopted a "basic budget" of $13,000,000, with an expansional budget of $2,000,000, about the same as that of 1925. The total membership of the Church in 1925 is 1,873,859, at home and abroad, which is the largest in its history, a gain for the year of 42,931.

PRESBYTERIAN CHURCH IN THE UNITED STATES (SOUTHERN)

The General Assembly.—It met in May at Lexington, Ky. The question of the right of women to speak on the floor of the church courts came up again in this conservative body which reaffirmed previous deliverances to the effect that it is "the settled doctrine of our Church that women are excluded from licensure and ordination by the plain teachings of the Scriptures, and, therefore, cannot be admitted to our pulpits as authorized preachers of the Word," nor can they be allowed to exhort or "pray or discuss any question publicly in the mixed meetings of the congregations." The Assembly added that presenting a report to a church court of work done by auxiliary or other associations "is not to be construed as speaking or discussing, provided the women presenting them do not discuss them." There are no bars of this kind in the Northern Church, though Dr. Theodore L. Cuyler, of Brooklyn, was once taken to task for allowing a well-known Quakeress to speak in his Church.

Other Presbyterian Bodies.—There are two other considerable Presbyterian Churches, the Cumberland, which stands in a doctrinal position midway between Calvinism and Arminianism, and the United Presbyterian, which is largely of Scotch origin, and for some years prohibited the use of organs in public worship and the use of modern hymns, holding to Rouse's metrical version of the Psalms. The latter body is known for its enthusiastic support of its benevolences and for its high per capita giving.

There are also two or three bodies of Cameronians or Covenanters, bearing the word Reformed as part of their titles, and two colored bodies.

PROTESTANT EPISCOPAL BODIES

By H. K. Carroll

Corresponding Secretary, Asbury Memorial Association

PROTESTANT EPISCOPAL

General Convention.—Its General Convention consists, unlike any other ecclesiastical body in this country, of two Houses—a House of Bishops and a House of Deputies, each House meeting separately under its own officers. Concurrence of the two Houses is necessary to any act of legislation. The Convention held its triennial session in New Orleans, La., in October, 1925. Much important business, executive and legislative, was accomplished. The Book of Common Prayer, which has been under process of revision through many years by a Commission of Revision, was taken up by the General Convention for discussion and amendment at the point where it was left by the Convention of three years ago. Action was completed upon the tentative acceptance of the previous General Convention. These involved minor changes in the rubrics on morning and evening prayer, changes in Communion, which were ratified, excepting additional commemoration of the departed in prayer, the printing of the *Agnus Dei*, and a few other proposals; changes in the collects, epistles and gospels, including one in the marriage service, dropping the word "obey" in the bride's answer, the responses of man and woman being identical; a new office for visitation of the sick was added, changes in the burial service, including a new office for children; changes in the ordinal. All these emendations were finally approved. Among the proposals of amendment adopted tentatively for final action by the next Convention were these: allowing "intinction" bread dipped in wine, without offering the cup to laymen; in the burial office having reference to the dead who die unbaptized, by suicide, etc. The Thirty-Nine Articles are to be omitted, if the next Committee ratifies.

Heresy Trial.—The heresy case of Bishop Wm. M. Brown, of Arkansas, was before the House of Bishops at several sessions. He had been tried on charges of heresy, involving, it was contended, the personality of God, the historic reality of Jesus Christ, and the efficacy of His grace through the Church sacraments, had been found guilty, and expulsion or deposition recommended. He had appealed to an appellate Court which had approved of the verdict and recommendation. Final appeal was taken to the House of Bishops, which, after discussion, voted, 95 to 11, Bishop Brown first speaking for half an hour, to confirm verdict and sentence. The House notified the Presiding Bishop of its action and the case ended. Bishop Brown, in his statement, denied that he was an atheist or ever had been. He claimed to accept the Apostles' and Nicene creeds as symbols of his belief, but not as intellectual views, and denied that he had changed any of the beliefs set forth in his book, for which he had been condemned. He asserted that a generation has grown up which considers that ecclesiastical censures are as dead as the divine right of Kings. Stripped of all episcopal and ministerial powers, he remains a layman, simply, of the Church in which he has served so many years. It has become known that some time ago Bishop Brown was admitted to the Old Catholic Church, which came into being after the Vatican Council, as a protest against the dogma of papal infallibility, on confession of faith and without relinquishing his relation to the Protestant Episcopal Church.

None of the cases arising in the diocese of New York in connection with modernism came before the General Convention, and the excitement caused by acts and expressions of some of the rectors appears to have subsided.

The announcement was made that though the contributions for the work of the Church had risen to more than $11,000,000 annually there was a deficit of $1,400,000. This was raised on the floor of the House in a few minutes, Bishop Manning taking the lead with a pledge of $250,000 for New York.

Presiding Bishop Elected.—An election was held for Presiding Bishop of the Church and also for President of the National Council, a general executive Commission administering the general missionary and other denomination work of the Church. From the latter, Bishop Gailor, of Tennessee, retires at the end of his term, and from the former, Bishop Talbot. Among those nominated for both were Bishop Brent, of Western New York, Bishop Gailor, Bishop Burleson, of South Dakota, Bishop Murray, of Baltimore, and Bishop Brown, of Virginia. The choice fell upon Bishop John Gardner Murray, one of the younger Bishops, who entered the Episcopal Church some years ago from the Methodist Episcopal Church. The term of the office in each case is six years. Bishop Murray becomes both Presiding Bishop and President of the Council. The occupant is relieved of diocesan work, resides in New York, and receives a considerable salary fixed by the General Convention and paid from its budget.

Relations with the Federal Council.—A considerable discussion took place on the question of joining the Federal Council of the Churches of Christ in America, consisting of about thirty bodies. The Church has been in coöperation with two Commissions of the Council, but has not become a constituent member. Two years ago the House of Bishops favored membership, but the House of Deputies opposed. The differences at New Orleans were sharp, those who opposed evidently inclining to High Church views, looking rather to the Eastern Churches for alliance than to the Protestant group. Bishop Brent pleaded with great passion and force of utterance for the proposed step forward, while Bishop Gailor characterized it as "dangerous." It was defeated by a tie vote; a two-thirds majority being required, but later on it was agreed that the Church should be represented on seven of the Council's commissions, instead of two simply.

Title.—A proposition, often made before, to drop the word Protestant from the title-page of the Book o Common Prayer, as the name of th Church, was brought forward an after a hot discussion was voted down the contention of the proponents bein that the Church belongs to the Catholic order of Christianity and not t the Protestant. The question whethe ministers should be allowed to reserve the elements of the communion lef after the service, was declared in the negative, low churchmen accusing the Catholic party of desiring to reserve it, not simply for the sick, but fo adoration as the mass.

The Rev. Dr. E. M. Stires, of New York, served as President of the House of Deputies very acceptably and retired at the end of the Convention to become Bishop of Long Island

The pastoral letter.—Issued by th House of Bishops at the close of the Convention, this speaks of an amazing growth of wealth with no corresponding increase of stewardship, of a lowering of standards of home life due to lack of parental control and of a widespread revolt against Christian morality indicated in literature, especially. The increase in juvenile crime is ascribed to want of Christian education. The remedy for this state of things is the preaching of the Gospel of Christ with new power. This is the hope of the world. Continuation in the ministry must depend on loyalty to the creeds. Faith in Christ is greater and simpler than assent to intellectual propositions.

Anglo-Catholic Congress. — This body, which represents those ministers and members who find themselves in sympathy with the position of the Church of Rome on most points, excepting principally the doctrines of Papal Infallibility and the Immaculate Conception, held its first Congress in the United States, after the Episcopal General Convention, meeting in New Haven, in November, 1925. There are various parishes where Catholic practices, the mass, auricular confession, etc., are observed. They lay stress upon the sacramental life and urgently desire fraternity with the Church of Rome and the Orthodox Eastern Churches. A paper was read at the Congress, in which it was contended that Anglo-Catholics have nothing in common with Protestantism. One of their aims is to eliminate the word Protestant from the title of the Church. They recognize monasticism, and have two orders, with vows—the Society of St. Paul the Evangelist, and the Holy Cross. "Father" Campbell, a member of one of them, was released from his monastic vows when he was consecrated Bishop of Liberia. Several bishops attended the Congress, and Bishop Burgess, of Connecticut, warmly welcomed it. In the Church of England, where the Catholic party is both older and stronger, it seems to have less favor from the Bishops than in this country. The Bishops of the Canterbury Province recently met to consider the question of prayer-book revision. The Catholics are understood to desire an alternative revision which will recognize some of their practices. To this some prelates decidedly object, though they recognize the need of changes in the ritual, which have been delayed two centuries.

Cathedrals.—Among notable recent enterprises in the Church is the erection of a great cathedral—St. John the Divine—in New York City, to whose pulpits representatives of all Christian denominations are welcomed, and the adoption of plans for a cathedral in Washington, D. C. Contributions of many millions for the New York minster have been sought and obtained, and construction is proceeding rapidly, the cornerstone of the nave having been laid in November, 1925.

REFORMED EPISCOPAL

A small body seceding from the Protestant Episcopal Church many years ago under the leadership of Bishop Cummins have several bishops in the United States and one in Canada. Their position is favorable to union, as their organ represents, since they are evangelical, liturgical, episcopal and democratic. They also claim to be comprehensive as appears in the union of episcopal oversight in parochial self-government. They baptize by sprinkling, aspersion and immersion, and recognize in both theory and practice the validity of all properly constituted ministries and the regularity of the membership of all Christian Churches, who are invited to their communion tables.

ROMAN CATHOLIC

By H. K. Carroll

Corresponding Secretary, Asbury Memorial Association

JUBILEE YEAR

Rome.—The See of Rome, the center of the world-wide Catholic Church in government and supervision, was the goal of Catholic interest and Catholic pilgrimages in 1925, which had been proclaimed as Holy Jubilee Year by the Pope. This event recurs on every twenty-fifth year in the calendar of the centuries, and is a usage which goes back through many centuries. The Papal bull permitted all the faithful who should make the pilgrimage to Rome in 1925 a plenary indulgence under certain conditions, among which were these: fervent confession and reception of the communion, from which no one could be excused except those who were unable to attend; visits to the basilicas of St. Peter, St. Paul, St. John Lateran and St. Mary Major in Rome, at least once in the day for the ten consecutive days; prayers for the intentions of the Pope.

Great numbers of the faithful made the pilgrimage from the United States and other countries to Rome during the year, and many were the preparations made for their reception and instruction. Among other things a great map, said to be the largest in the world, was displayed in the Congregation for the Propagation of the Faith, in charge of Catholic Missions throughout the world, showing the vastness of the missionary enterprise in all quarters of the globe.

Missionary Exhibit.—A missionary exhibit occupied ten temporary buildings 50 by 200 feet each in size. Besides these there were tributary buildings and one of the corridors of the Vatican Museum four hundred feet long was given to the display. Among the rooms especially interesting were those of the Holy Land, of the Martyrs, the latter embracing many scenes of martyrdom and instruments of torture used upon Christian martyrs. The breviary and sandals of St. Francis Xavier, missionary to India, are shown, and sabers used in the Boxer uprising in North China, a few years ago, to massacre faithful Chinese Christians who would not abjure their faith. Also a statue of Pope Gregory, who receiving the deputation from pagan England—with "angles, slaves of fair complexion"—called them "angels rather," and sent preachers to the British Isles. Challenges to increase missionary labor appeared in placards like the following: "Bengal, 15,000 Catholics, 19,000,000 pagans, with but 19 priests to a million; 2,200 children in Catholic Schools, 8,000,000 yet to reach." It is said that Pope Pius XI, following the example of Leo XIII, twenty-five years ago, will issue a bull extending the jubilee indulgence of 1925, to 1926 for the whole world, particularly to those unable to come to Rome.

Ecumenical Council.—An Ecumenical Council is to be called for the Church in Rome, in 1926, at which new dogmas may, perhaps, be proclaimed.

Women's Dress.—A war against immodest dress in Catholic Churches has been in progress, beginning at Rome, where a circular issued by the Central Holy Year Committee gave notification that all women visiting churches in a garb in violation of the rules would be ejected. All the Italian bishops published pastorals on the subject.

Boy Scouts at Rome.—Among the bodies in Rome during the Jubilee Year to attract attention were the Boy Scouts from America, England and others. As they paraded the streets they were the observed of all observers and they were honored by the Pope with an audience in which he addressed them quite at length welcoming them to the Vatican and praising them for their marching order and fine appearance.

The Catholic Union.—Another body in which America is represented has, as its aim, the promotion of union of the Eastern Orthodox Churches, the outcome of the division of Christendom at the end of the first thousand years of Christianity, by the separation of the two Capitals, the Eastern, Constantinople and the Western, Rome. Some of these Oriental Churches have long had representatives in the Church of Rome, called uniates, who have certain ecclesiastical privileges, such as celebration of certain rites in their own language instead of in the Latin, and marriage of the secular as distinguished from the monastic clergy. There are considerable bodies of uniates in the United States as well as of the Russian, Greek, Bulgarian, Roumanian, Syrian and other Eastern Orthodox bodies.

POLISH CHURCH

Near the end of 1925, a Polish prelate, Archbishop Cieplak, for many years head of the Roman Catholic Church in that country, made a visit to the United States. It appears that the Soviet Government confiscated and sealed 328 Catholic Churches in Russia, and in March, 1923, arrested the Archbishop, with fifteen priests and placed them in prison. The former was condemned to death, but escaped. He has since been appointed Metropolitan of Vilna, Poland.

Conventions.—Annual meetings are numerously attended and influential. That of 1925 was held in Duluth, Minn. It represented a body of 751,882 members in the United States and Canada, a loss in 1925 of 18,442. There is also a National Council of Women, the fifth annual convention of which was held in Washington, D. C., in November. One of their decisions was to raise $600,000 for the National Catholic School of Social Service, which has been in existence five years. Education, immigration, girls' welfare, peace, rural problems and women in industry were among the subjects considered by the Council. An invitation was received and accepted from Cardinal Mundelein, of Chicago, to attend and assist in making known the Eucharistic Congress in 1926, in Chicago. He said Chicago is idealistic and that the time has come to assert the fact that while America is said to be the land of unbelief it is in reality less so than other countries. The Council condemned immodest dress of women, birth control and the downward trend of literature.

The Catholic Educational Association.—This body reports on Colleges and Secondary Schools, setting forth the need of a constructive policy in Catholic education, of the development of the parish school system and of the needs of the seminaries and libraries.

Many Catholic churches observed in December, 1925, the sixteenth centenary of the Nicene Creed, one of the ecumenical creeds accepted by most orthodox churches of the Protestant as well as the Roman Catholic and Eastern Orthodox communions. It was adopted in 325 to combat the Arian heresy.

Rural Churches.—The Roman Catholic Church has its rural problems as do other churches in the United States. The migration from the country to the centers of population causes many heretofore prosperous churches to grow weak to the point of abandonment. The first diocesan council of the kind was held in Baltimore, in October, 1925, at which it was stated that the chief aims of the movement are the privacy of the family and assertion of private ownership of productive property. City living is not helpful to family life but rural living is, it was declared; and the future of the Church lies in the country.

The thing to be done is to anchor to the land the largest number of capable and imaginative members of the newer generation. The country pastor, with this object in view, should study the economic situation of the farmer, social and intellectual life on the farm, and condition of health. Farm industries need to use electric power and other modern appliances. Vacation schools should be established for the teaching of modern methods. Another such conference was held in New York, at which it was said that there was not a diocese in the United States which has not a rural problem.

JUDAISM AND JEWISH COMMUNAL ACTIVITIES

By Bernard G. Richards

Executive Secretary, American Jewish Congress

Religious Education.—The year 1925 closes an important chapter in the history of the American Jewish community. It was the first year since the enactment of the new Immigration Law, which reduced the number of Jewish immigrants to an insignificant figure estimated to be one-fifth of the volume of Jewish immigration to the United States as reported in the previous year. Despite the prevailing opinion that the future of Judaism in the United States is largely dependent upon the volume of European immigration, the arrival of large numbers more deeply imbued with Jewish religious teachings and traditions, the past year, proved the opposite. Regardless of the curtailment of this immigration, Jewish religious, cultural and educational activities have taken a new and more intensive form.

While the Jewish population in the United States is roughly estimated to be about 3,000,000, the sum of not less than $7,000,000 is being spent annually for the purpose of instructing the young in the teachings of the Jewish religion, history and the Hebrew language. These activities in most instances run parallel to extensive work for the general education and Americanization of the immigrant. Schools of various types, ranging from Sabbath schools, with English as the language of instruction, to part-day and full-day Hebrew schools, with Hebrew and in some instances Yiddish as the language of instruction, are functioning in every considerable center with a Jewish population. Leaders of this movement have continually emphasized the fact that these schools do not reach more an 50 per cent. of Jewish children of school age, expressing uneasiness about the lack of facilities religiously to educate the rest.

Synagogues and Community Centers.—A very intensive activity developed during the year with regard to the construction of synagogues and community centers. These community centers represent a new institution in the American Jewish life, designated to serve the religious and cultural interests of the group. Designed as a meeting-ground for the young and old, these centers serve as a medium for social recreation and for the development of cultural and religious activities. Not less than 85 buildings were erected or were under construction during the year in 85 communities. The cost of erection ranged from $2,000 to $200,000.

Training of Rabbis.—Of primary interest in this direction were the activities of the four institutions which have for their purpose the training of rabbis and leaders for the Jewish communities. Though belonging to four different shades of thought, they represent in their totality an effort towards one common need: to preserve Judaism in the modern American environment. The Hebrew Union College, Cincinnati (Dr. Julian Morgenstern, President) which is the oldest American Jewish institution of learning, celebrated on October 26, 1925, its 50th anniversary. This served as an occasion for impressive ceremonies at the seat of the College, where all the alumni and leaders of the reformed Jewish pulpit were present. Coincidentally was held the 21st Annual Convention of the Central Conference of American Rabbis, the representative body of the reform movement, which was initiated by the late Dr. Isaac M. Wise, the founder of the Hebrew Union College. Six students graduated as rabbis from the Hebrew Union College in 1925.

Jewish Theological Seminary.—The Jewish Theological Seminary, of America, situated in New York City, of which Dr. Cyrus Adler is President, stands for Conservative Judaism. It is an institution which trains its graduates in the support of traditional Judaism. This shade of belief is commonly known as that of the conservative tendency in Judaism as between the reform and the ultra-orthodox. Fifty-one students graduated from this seminary as rabbis and twenty-one graduated from its Teachers' College during the year.

Institute of Jewish Religion.—This was recently established in New York City with Dr. Stephen S. Wise as the acting President. Though it is closely to be identified with the liberal movement in Judaism and is intended to supplement the training, which is carried on in Cincinnati, in the larger community of New York, the Institute is, at the same time, of an original character in view of the fact that it has for its model the type of a free synagogue standing for a generally progressive and forward-looking outlook and an emphasis on the spiritual rebirth of Israel in ancient Judea as conceived and propounded by its acting President. Eight students of this institution graduated during the year, while the first large graduation is expected to take place in May, 1926.

The Yeshiva.—The ultra-orthodox group of congregations looked for their inspiration and religious leadership to the Yeshiva (Isaac Elchanan Seminary), of which Dr. Bernard Revel is President, a purely orthodox seminary, which was originally established in New York City 28 years ago. Twelve rabbis graduated from this institution during the year and eighteen teachers. An important development in this school is the plan to transform the Yeshiva into a Yeshiva College, which would combine a broad Jewish and Talmudic education with a college course for its students, being the first of its kind, a college modelled along parochial lines. A campaign for $5,000,000, of which $2,000,000 has already been raised, is on the way to secure the erection of five modern buildings at Amsterdam Avenue and 124th Street, New York City.

Synagogue Plans.—Two outstanding projects with regard to the construction of synagogues attracted wide attention among American Jews. One was that of erecting a Synagogue Center in Jerusalem at the cost of $500,000. This plan which was originated by the United Synagogue of America, an organization of recent date, comprising those congregations which belong to the conservative type, is unique in its scope, representing the first effort in behalf of American Jewry to do religious work among the pioneers in Palestine. It is also significant that the Synogogue Center, which is the result of American Jewish conditions, is being transplanted to the Holy Land. The other plan is to erect a national reform temple in Washington. The plan is fostered by the reform rabbis, headed by Dr. Abram Simon of Washington, former President of the Central Conference of American Rabbis.

Protection of Jewish Rights.—The tradition of American Jewry to take an interest in the political, cultural and economic welfare of the frequently troubled Jewish communities in European lands was continued through the year. The American Jewish Congress, an organization created during the war, and subsequently maintained for permanent purposes, consisting of delegates from various national Jewish organizations and committees throughout the United States, held its biennial session in Philadelphia October 25 and 26, 1925. Reports of activities in connection with the protection of Jewish rights, help extended to stranded Jewish refugees, the combating of anti-Semitism, etc., were then presented to the delegates. Mme. Anitta Mueller-Cohen, the widely known Jewish social worker of Vienna, and Dr. Leon Reich, President of the Club of Jewish Deputies in the Polish Scheim, delivered the chief addresses. The Congress organization, for a number of years headed by Nathan Straus, is now actively presided over by Dr. Stephen S. Wise, with Carl Sherman as Chairman of the Administrative Committee.

The American Jewish Committee, made up of notable men in Jewish life in different parts of the country, and presided over by Mr. Louis Marshall, held its annual meeting on November 9, 1925, and received reports on t Jewish situation in different lanc

The Independent Order B'nai Brit now headed by Alfred M. Cohen Cincinnati, and the Independent C der Brith Abraham, Adolph Ster Grand Master, as well as other frate nal organizations and federations, c operating in work of a patriotic ar philanthropic character, held impo tant gatherings during the year.

Foreign Relief.—Further efforts f the relief of suffering Jews in var ous parts of the world are now bein undertaken by American Jewry. I addition to the $60,000,000 raised b the Joint Distribution Committee du ing and after the war, a national con ference of representative Jews hel in Philadelphia on September 13, d cided to empower the committee t launch an appeal for $15,000,000, t be raised in the course of the nex three years for the purpose of bring ing relief to the suffering Jewis communities in Eastern Europe an mainly in Russia.

In continuation of the work on be half of the American Jewish Com munity for the reconstruction o Palestine as the Jewish Nationa Homeland under the mandate of th League of Nations, entrusted to Grea Britain, a call for $5,000,000 has bee issued by the United Palestine Ap peal, composed of various Palestine activities and headed by Dr. Stephen S. Wise.

Literary and Journalistic Activities.—Mention might be made of the continued issue of important Jewish books by the Jewish Publication Society, Simon Miller, Philadelphia, President; the extension of influence on the part of the *Menorah Journal*, a high class literary publication, initiated by college men, and now being spread to other circles, under the editorship of Henry Hurwitz; the establishment by the Jewish Telegraphic Agency of the *Jewish Daily Bulletin*, a miniature but comprehensive record of Jewish events, of which William Z. Spiegelman is the editor and Jacob Landau the publisher.

PART SIX
SCIENCE—PRINCIPLES AND APPLICATION

DIVISION XXVIII
MATHEMATICS AND ASTRONOMY

MATHEMATICS

By G. A. Miller
Professor at University of Illinois

Mathematical Monographs.—Among all scientists the mathematicians have developed the most extensive special languages and hence the results of the modern mathematical investigators require the most exhaustive expository developments in order to make them directly useful to those who could profit thereby. The year 1925 marks the beginning of the publication of two series of monographs which promise much along the line of such developments relative to advanced fields of modern mathematical research. One of these is an American series known as the *Carus Mathematical Monographs,* which are being published under the auspices of the Mathematical Association of America through funds provided by Mrs. Mary Hegeler Carus. The other is a French series known as *Mémorial des Sciences Mathématiques,* which appears under the patronage of the French Mathematical Society and various other scientific organizations, including the scientific academies of Paris, Servia, Belgium, Bucharest, Poland, Ukraine, Spain, Prague, Rome (dei Lincei) and Sweden. It is published under the general direction of M. Henri Villat, editor of Liouville's *Journal de Mathématiques.*

The first of the Carus Mathematical Monographs is devoted to the *Calculus of Variations* and was prepared by Professor G. A. Bliss, University of Chicago, who has for many years worked successfully in this field and has directed a large number of theses by graduate students who investigated special problems related thereto. It presents in an unusually clear manner the fundamental elements of this wide and fruitful subject, presupposing only a first course in elementary differential and integral calculus. These monographs are supposed to be comprehensible not only to teachers and students specializing in mathematics, but also to scientific workers in other fields, and especially to the wide circle of thoughtful readers who, having a moderate acquaintance with elementary mathematics, wish to extend this knowledge without prolonged and critical study of the mathematical journals and treatises. The French series of monographs is intended for those who have higher mathematical attainments and its publication has progressed much more rapidly. The first number was written by P. Appell, University of Paris, and appeared under the title *Sur une forme générale des équations de la dynamique.* This series takes the place, in part, of the publications of the large French mathematical encyclopedia which was discontinued during the World War, and a large number of monographs forming a part thereof have been announced as either in press or in preparation.

Chauvenet Prize.—During the Ithaca meeting of the Mathematical Association of America, which was held in September in conjunction with the American Mathematical Society, the trustees of the Association instituted a prize to be known as the Chauvenet Prize for Mathematical Exposition, which is to be awarded every five years for the best expository mathematical journal article by a member of the Association, published in English during the five calendar years preceding the award. Professor E. B. Van Vleck, University of Wisconsin, was appointed chairman of the scrutinizing committee for the first award, which is to relate to the five years ending with the calendar year 1924. Two additional American mathematical prizes have recently been established, viz., the Bôcher Memorial Prize, announced in 1922, and the Frank Nelson Cole Prize in Algebra, announced in 1923. Both of these perpetual prizes are under the auspices of the American Mathematical Society and are to be used for the promotion of mathematical research. Unfortunately the amount of money available for the encouragement of such work in our country is still too limited.

Recent Advances.—The thirty-first summer meeting of the American Mathematical Society was held at Cornell University September 8-12 for the purpose of discussing current advances. Most of these advances are presented briefly by their authors in the form of abstracts of papers which appear later in the various mathematical periodicals, but sometimes series of lectures are also given on fields of research which seem to offer unusually attractive and important problems, especially for the younger investigators. These lectures are published later under the auspices of the American Mathematical Society and are known as the "Colloquium Lectures" of this Society. During the meeting under consideration two such courses of five lectures each were given by Professor L. P. Eisenhart, Princeton University, and Professor Dunham Jackson, University of Minnesota, respectively. Professor Eisenhart considered "New Differential Geometry" and developed in a masterly manner and often from a new point of view many recent results in a field which has been greatly enriched by his own investigations. Professor Jackson considered the "Theory of Approximation," with his unusual gift of clear presentation. He, too, has contributed extensively towards the development of the general subject considered by him at this time and pointed out new methods for its further study.

More than fifty other mathematical papers were presented at this meeting, evidencing the growing vigor with which mathematical research is now being prosecuted in our country. The papers were distributed under four headings as follows: Geometry, Point Sets and Foundations, Analysis, and Algebra and Theory of Numbers. In order to allow more time for discussion, meetings were held simultaneously in different rooms, due notice being given as to the time when the various papers were to be considered. Each paper was supposed to represent, and probably did represent, an actual advance whose importance cannot be fully appreciated now since some apparently slight variations in point of view are often fraught with the most important consequences, while other distinct advances remain less fruitful. There naturally is, however, a feeling that some of the researches are more important than others but this feeling is not always justified by later developments. The criterion of such developments is perhaps stressed too little since some authors desire immediate recognition.

The American Mathematical Society holds regularly seven meetings during the year, while three additional meetings are usually held west of the Mississippi River by sections thereof. All of these meetings are devoted mainly to the consideration of current researches on the part of its members and a few others. In view of the definiteness of mathematical advances these meetings present a very inspiring picture of the growth of the intellectual wealth of the human race along a certain line, especially when it is remembered that similar work of an equally high character is being done in various other countries. It is sometimes assumed that much of this work is only of transitory value. While a great deal of it may lose its identity as it is being embodied in more comprehensive theories, it has accomplished an important function in helping to make possible these new theories, which, in turn, usually give rise to something better. In view of the multitude of the new results it is often difficult to select a representative list which can be described in a brief space.

Jacques Hadamard.—Professor Hadamard, Collège de France, Honorary member of the London Mathematical Society and one of the six members of the pure-mathematics section of the Paris Academy of Sciences, spent about two months in America (April 26 to June 17) in travel and in lecturing at the Universities of Illinois, Wisconsin, Indiana, California, Stanford, and Rice Institute, on the following subjects: Huygens' principle; some recent points of view on the notion of functions; second period of the work of Poincaré on differential equations; and some recent improvements in the geometry of circles in space. In his opening lecture Professor Hadamard commented on the rôle played by errors in the development of mathematics, illustrating his remarks by erroneous published views relating to Huygens' principle. Obviously such errors tend to advance mathematics only when they are clearly pointed out and there seems to be a growing tendency to deal frankly with errors even if this course still meets with occasional opposition. While mathematics deals in the main with matters that can be definitely proved, a considerable amount of mathematical progress has resulted from noting contradictions due to false assumptions made by some of the foremost investigators or to inaccuracies in their developments. Fortunately the literature used in secondary schools is comparatively free from such errors but even here there is often much room for improvement, especially as regards clarity and definiteness.

History of Mathematics.—The publication early in 1925 of volume 2 of the *History of Mathematics* by D. E. Smith, Teachers' College, Columbia University, completed a work which was awaited with much interest on the part of many American teachers of mathematics in view of the eminence of its author along pedagogical and historical lines, and the unique character of the work. It is not only the most extensive so-called general history of mathematics ever published in our language, involving about 1,350 pages, but it devotes an unusually large amount of space to questions relating to the older and most elementary developments, and presupposes very meager mathematical attainments on the part of its readers. It aims to arouse interest not only by referring frequently to curious non-mathematical facts but also by including some fiction, for instance, the portraits of Plato and Leonardo Fibonacci are explicitly acknowledged to be unauthentic, (volume 1, pages 87 and 214). Fortunately, the element of fiction affects only slightly the reliability of the work as a whole since it is usually clearly exhibited, as in the instances just noted. The number of actual misstatements is somewhat large but probably most of these will be corrected in later editions. In the meantime it is a good exercise for the student to try to find such statements.

The most serious question relating to this history of elementary mathematics is its possible influence on the teaching of mathematics in our high schools. As comparatively little emphasis has thus far been placed on the history of mathematical subjects the effect of the present work will be watched with much interest on the part of those who are directly concerned with our mathematical development. The literature of various other countries includes a number of very brief outlines of the history of elementary mathematics and recently there appeared in Germany an equally extensive work devoted to this general subject but written from a widely different point of view. In fact, as regards the extent of recent popular mathematical historical textbook literature America occupies now a conspicuous position. Some of the subjects considered in the present work, in particular those relating to the mathematics of the Orient, have as yet received too little attention on the part of historians to be finally settled. It is therefore to be hoped that much fruitful discussion will center around this publication. In fact, a slight beginning along this line has already been made. [Cf. *School Science and Mathematics*, vol. 24 (1924), p. 939.]

The most important feature of the history of mathematics is its portrayal of a fundamental element of the history of civilization, viz., the element relating to the intellectual penetration into our surroundings based on numerical relations. The value of this feature has always been recognized and it is illustrated by the fact that mathematics has occupied a prominent position in nearly all the educational systems of the world of which we have any record. The modern tendency in the development of mathematics has been towards greater emphasis on the number concept and it is sometimes said that this tendency was inaugurated by A. L. Cauchy (Cajori, *History of Mathematics*, 1919, p. 369). On the contrary, attention was recently called (*Science*, vol. 62, p. 328) to the fact that arithmetization is a fundamental principle in the history of mathematics, comparable with the principle of evolution in the natural sciences. Such fundamental concepts as the irrational, limit, function, coordinate, etc., were slowly arithmetized, so that arithmetization has played at least as fundamental a rôle in the developments of elementary mathematics since the golden Greek period as in the more recent investigations relating to modern mathematics.

Personal Notes.—Professor S. Lefschetz, Princeton University, was elected member of the National Academy of Sciences. Professor G. D. Birkhoff, Harvard University, was elected President of the American Mathematical Society. Professor J. L. Coolidge, Harvard University, was elected President of the Mathematical Association of America. Professor R. Schorling, Michigan University, was reëlected President of the National Council of Teachers of Mathematics. Professor W. H. Roever, Washington University, was elected chairman of the Mathematics Section of the American Association for the Advancement of Science.

Klein.—Professor F. Klein, Foreign Associate of the National Academy of Sciences, died at Göttingen, Germany, June 22, 1925, at the age of seventy-six. During the World's Columbian Exposition, held at Chicago in 1893, he delivered a series of inspiring lectures which were published by the American Mathematical Society under the title *Evanston Colloquium*. A large number of American students studied with him at the Universities of Leipzig and Göttingen.

According to *Nature* (vol. 116, p. 476), "It appears, what will be news to many, that Klein's life was lived under a resolve, never relinquished, made when serving Plücker as assistant for his lectures on experimental physics, to devote himself to physics. He desired only, first, as a preparation for this, to make himself acquainted with all branches of mathematics, in order to trace the connections of their leading ideas, and to be in position to raise physics to a higher plane." This resolve was realized only in the work of students whom he inspired and was partly modified by a serious breakdown of health at the age of thirty-three. With a view to bringing under one point of view a large part of the mathematical output of the last century he emphasized the group concept. In particular, his Erlangen Programme, translated by M. W. Haskell, University of California, for the *Bulletin* of the American Mathematical Society [vol. 2 (1893), p. 215] exhibits the unifying principle of this concept in recent researches in geometry. Since 1908 Klein devoted a large part of his time to the work of the "International Commission on the Teaching of Mathematics" of which he was President, and under whose general supervision an extensive literature relating to the teaching of mathematics in various countries has arisen. Unfortunately the World War made it impossible to continue this work, which promised much for the general improvement in the teaching of mathematics.

Another important mathematical world movement in which Klein was the most influential figure relates to the large mathematical encyclopedias in German and French. Unfortunately, here too the World War interrupted the work and led to serious curtailments. Klein was not only one of the originators of this encyclopedia but he traveled far and near to secure the best writers for the various parts thereof. He was especially sympathetic with the emphasis on mathematical physics found in England and deplored the fact that German mathematicians laid less stress on this contact of their subject. While his original memoirs (which were collected recently and published in three large volumes) are very inspiring yet he exerted his greatest influence by suggestions during discussions and by lectures. Probably no mathematician exerted a wider direct influence during the last half century. The impress which he made on mathematics as a whole, including the elementary parts thereof, is one of the outstanding facts in the history of recent mathematical developments. It may therefore be a matter of surprise to many that his name does not appear in the extensive indexes of the history of elementary mathematics noted above, especially to those who believe that the mathematical student should become acquainted with the history of the most important current movements in his special field as early as may be possible.

ASTRONOMY

By Raymond S. Dugan
University Observatory, Princeton University

Meeting of the International Astronomical Union.—The third meeting of the Union, which was organized at Brussels in 1919 and which convened again in Rome in 1922, was held in July at Cambridge, England. Twenty countries were represented by delegates. Coöperation is peculiarly necessary in astronomy: the personnel is small; observatories are few, and the instruments of research expensive; many of the problems are large and must be attacked from various angles over a period of years and from various points on the earth's surface, and the expense of research and printing borne internationally; and, finally, rapid progress is possible only if effort is wisely directed with the aid of consultation with other workers in the same field.

While coöperation has always existed among small groups of astronomers, and while the participation of observatories in the elaborate undertakings of the *Astronomische Gesellschaft* Catalogue, the photographic *Carte du Ciel* and the Solar Union have shown the possibility of coöperation on a large scale, the I. A. U. now forms a general clearing house of all matters of importance to the science of astronomy. The organization includes twenty-six committees or "commissions," such as those of Notations and Units, Bibliography, Ephemerides, Wave-lengths, Double Stars, Variable Stars, etc., composed of specialists in these fields, which prepare and present to the meeting reports of progress and recommendations. These form the basis for discussion during the meeting. It is not possible, in the space available, to mention all the important decisions reached at the meeting. A special committee will consider the designation of time counted from midnight and the hour of commencement of the Julian Day.

Designation of Time.—Up to 1925, the positions and other data of the sun, moon, and planets published in the national almanacs and ephemerides were given for noon, and astronomers and navigators reckoned with the day beginning at noon and employed, in their methods and formulæ, Mean Time (local or Greenwich) counted from noon and, therefore, equivalent to the hour angle of the Mean Sun. The change to the use of the Civil Day, beginning at the previous midnight, was made on January 1, 1925, with a view to simplification and the removal of confusion. The old confusion has been replaced by new. As the designation of the time since Greenwich midnight, the American Ephemeris uses Greenwich Civil Time (G. C. T.); the Nautical Almanac (English) retains the old designation, Greenwich Mean Time (G. M. T.), in the new sense; others suggest the adoption of "Universal Time." Unfortunately the committee was unable to report that there was yet sufficient accordance of opinion among astronomers to warrant a decision as to the best designation. It was decided, however, to continue the noon beginning of the Julian Day, as the use of this unit of time, for the ready calculation of the time interval between two observations, is almost entirely confined to astronomers.

Multiple Names of Stars.—A committee was formed to revise the boundaries of the constellations so as to avoid multiple names for stars. Accounts were given of work being done on the construction of large glass reflectors, with a composite glass back and a relatively thin glass disk in front, and of experiments looking to the use, for this purpose, of fused silica, which shows negligible deformations with temperature changes. Support was given to the project of a solar observatory in Japan to bridge the gap between Mt. Wilson and Kodaikanal and thus to make more possible continuous observation of the sun. Observatories were urged to make observations of the sun, as nearly continuous as possible, at or about the times when magnetic storms were in actual progress or were to be expected in accordance with the twenty-seven-day cycle. It was agreed that the variation of the solar radiation ought to be more generally studied with special reference to its influence on meteorological elements in different parts of the world. Four lines in the spectrum of Neon were adopted as secondary standards, from which the wave-lengths of other lines are to be determined, and an exact specification adopted for the production of the primary standard wave-length, that of the red line of Cadmium, $\lambda 6438.4696$.

Commission on the Determination of Longitude by Wireless reported plans for a world-embracing survey by means of "rhythmic signals" (permitting of the method of coincidences) sent from Bordeaux, Honolulu, Särgon, and Annapolis. The signals will be recorded at a small number of observatories, where the necessary observations for the determination of local time can be made with transit micrometers. It is planned to commence the experiments on October 1, 1926, and to continue them for two months. The report of the Commission on Stellar Photometry contained estimates by Seares and van Rhijn of the number of stars in the whole sky to the twentieth visual and the twenty-first photographic magnitudes as 1,000,000,000 and 890,000,000 respectively.

Southern Observatories.—General studies of the structure of the universe have been handicapped by the lack of material regarding the stars of the southern sky. Accumulation of data has progressed slowly, because of the comparative lack of instrumental equipment in the southern hemisphere. The work of the established southern observatories has been supplemented, to some extent, by more or less permanent expeditions from northern observatories. Harvard has a station at Arequipa, Peru, where the Harvard plan of repeatedly photographing the sky and the classification of stellar spectra is carried on; the Lick Observatory station at Santiago, Chile, was established to secure radial velocity spectrograms of southern stars. Yale Observatory has just installed at Johannesburg, South Africa, for a period of years, a 26-inch photographic refractor. This instrument will be used chiefly in the measurement of the distances of the southern stars. The same problem will form the chief program of the new 26½-inch telescope, which is being installed at the Government Observatory in Johannesburg, and of the 24-inch, which is the principal instrument of the new Bosscha Observatory established by the Dutch East Indian Astronomical Society at Lemberg, Java. Another 24-inch telescope is being sent out to Bloemfontein by the University of Michigan. It will be used for an extension to the South Pole of the double-star survey, already completed by Aitken and Hussey from the North Pole to 14° south declination, of all stars brighter than the ninth magnitude.

Eclipse of the Sun, January 24.—The total eclipse of the sun on the morning of January 24 was a very satisfying event. The shadow of the moon reached the earth at sunrise about 150 miles northwest of Duluth, Minn. Thence it traveled east, southeastward across Wisconsin and Michigan, Ontario, New York, Connecticut and Rhode Island and out into the Atlantic, where it again swung northward and left the earth north of Scotland. The belt of totality increased from a width of about 80 miles at the western end to one of fully 110 miles in Connecticut. It covered one of the most thickly populated sections of the United States and was easily accessible from a large bordering area. The area over which the eclipse was partial covered a large part of North America, the Atlantic Ocean and the eastern part of Europe and Africa. The observatories of Cornell, Vassar, Yale, Wesleyan, and Nantucket all lay near the central line of totality, so that it was possible for many astronomers to make observations with an unusual degree of convenience.

Across the United States the shadow of the moon traveled with great rapidity, as is always the case when the shadow strikes the earth's surface very obliquely, i.e., near sunrise or sunset. The rotational motion of the earth's surface is in the same direction as the motion of the moon's shadow and it thus reduces the velocity of the shadow past the observer. The eastward motion of the surface is slower, and the resultant velocity of the shadow consequently greater in high latitudes than near the equator. The entire stretch from Minnesota to Nantucket was traversed by the center of the shadow in about fourteen and three-quarters minutes. One hour and twenty-eight minutes later, the path of totality reached its abrupt end at sunset north of Scotland.

The duration of totality depends both upon the velocity of the shadow and upon its dimensions at the earth's surface. The circumstances of this eclipse were such that the duration of totality was relatively short, ranging, along the central line from Minnesota to Nantucket, from 83 seconds to 2 minutes and 7 seconds. In spite of the brevity of the eclipse, the small altitude of the sun, and the unreliability of New England weather, extensive preparations were made by many professional astronomers and numerous stations occupied near the central line. The *Los Angeles* was sent up by the Navy Department with a party of government astronomers, and airplanes were placed under the direction of other astronomers. While a cloudy sky brought disappointment to all those located from western New York State westward, nearly perfect atmospheric conditions prevailed, at the critical time, to the eastward, and results of great value were secured.

Public Interest.—A striking feature was the participation in its observation by the public. Any one near the boundary of the shadow, which lay through New York City, could, with a little instruction, make observations which would locate the boundary with great precision. Such observations would lead to a correction of the assumed position of the moon and add to our knowledge of its motion. The puzzling problem of the shadow bands might be solved from a large number of reports sent in by amateur observers; and a camera of any description could be usefully employed. A publicity committee was appointed by the American Astronomical Society to inform the public of what they might expect to see and of the observations which they might make. Newspaper cooperation, lectures and radio talks awakened a general interest and brought many offers of assistance.

On the morning of the eclipse airplanes started up carrying newspaper men, photographers and astronomers; trains arrived in the belt of totality with thousands of people from less favored regions; astronomers made a last inspection of their instruments; telegraph operators got ready to send and receive weather reports along the track; and business was suspended while everybody shivered in the keen winter air. Shortly before totality the so-called shadow bands came fluttering and quivering across the white snow; the slender crescent of the sun broke up into beads, and then was gone; the corona flashed out and the eclipse was on. The first reappearing bit of the sun was expanded by irradiation into a brilliant jewel set in the still continuous ring of the corona, and popular imagination coined the term, the Diamond Ring.

The scientific results accomplished far exceeded expectations. The times of contacts of the limbs of the sun and moon, photographs of the sun in the partial phases of the eclipse and the accurate delimitation of the shadow, in particular across New York City, provides material for the correction of the moon's place; photographs with cameras of various sizes during totality revealed the structure of the corona and the prominences; the photometric brightness, the radiation, the degree of polarization and the spectrum of the corona were all recorded during the few seconds of totality; photographs of the "flash spectrum," consisting of the bright lines radiated by the atmosphere of the sun were secured at the beginning and end of totality; the shadow bands, which were unusually conspicuous, were conclusively shown to result simply from the irregular transmission through the earth's atmosphere of the light from the slender remaining crescent of the sun, analogous, therefore, to the well-known phenomenon of star-twinkling. Other observations include the effect on magnetic and wireless conditions. A full account of the eclipse preparations, experiences and results may be found in the numbers of *Popular Astronomy*, from January on.

There were three other eclipses during the year: an annular eclipse of the sun in July, visible in the southern Pacific Ocean; and partial eclipses of the moon on February 8-9 and August 4.

Several eclipse expeditions started out in the summer on their long journey to Sumatra to observe the eclipse of January 14, 1926.

Comets.—The number of comet discoveries varies widely from year to year. The discovery of a new or unexpected comet involves patient sweeping of the sky, zone by zone, and the identification of numerous nebulæ which closely resemble comets. The search may be fruitless for months at a time and the observer have nothing to show (except the cultivation of patience and persistence) for his many nights' work. Very few observers continue their comet-seeking very long and the number of enthusiasts for this kind of observation is, in some years, very small.

Six new comets were discovered in 1925—the first three within a space of two weeks. The first (1925a) was found by Schain at Pulkovo on March 24, and a day later by Comas Sola at Barcelona; the second (1925b), on March 26, by Reid in South Africa; the third (1925c) by Orkisz at Cracow on April 4; the fourth (1925d), on November 17, by Van Biesbroeck at the Yerkes Observatory; the fifth (1925j) by Peltier and Wilk, November 13-19, and the sixth (1925k) by Ensor in South Africa, December 14. Schain's comet came to perihelion (the point nearest the sun) in September, at a distance from the sun of nearly 400 million miles. The perihelion distance is thus, apparently, even greater than that of the comet of 1729, which had hitherto held the record for perihelion distance. Comets of ordinary brightness are totally invisible at such a distance; this must be a very big comet to show up as an object of the eleventh magnitude. Reid's comet was comparatively bright and nearly reached the threshold of naked-eye observation in June. It passed perihelion in July, about 60 million miles outside the earth's orbit. It was then near the Southern Cross. Comet 1925c had just passed perihelion, at a distance of about 100 million miles from the sun, when discovered. At brightest it was about as bright as Reid's comet and had a short tail, but, with increasing distance, it faded rapidly. It traversed the northern constellations, passing, in June, within 8° of the pole. In addition to these unexpected appearances of comets, the returns of five periodic comets were observed with the aid of careful predictions of their places: Borrelly's comet was found by Schaumasse on August 14; Brook's, by Tscherny, on September 19; Wolf's (1884, III), by Stobbe, July 13; Tempel II, by Stobbe, June 11; and Faye's, by Baade, October 20. Two other comets, which have elliptical orbits, were due to return to the neighborhood of the sun during the year but they were not detected.

Mars.—Advantage was taken of the unusually favorable opposition of Mars in 1924 to gather some very interesting information concerning the planet which most readily excites our imagination. The October number of the *Pub. Astr. Soc. Pacific* contains some photographs (by Wright) of Mars, and of a view across the country from Mt. Hamilton, California. One pair of pictures was taken through a color screen, which allows only red light to reach the plate, another was taken in violet light. Of the photographs of Mars, the one in red light shows a wealth of detail of surface markings; the one in violet light, on the other hand, is of almost uniform appearance, with the exception of the polar cap, which is, relative to the other picture, very conspicuous. There is a similar difference in the terrestrial pictures: the atmosphere cuts off the violet light from the distant landscape, and, in violet light, nothing shows beyond the immediate foreground on the mountain top; in the other picture, taken in red light, the valley and the mountains beyond appear with great distinctness in detail. These facts, with other considerations, are suggestive of the existence on Mars of an atmosphere of considerable density. Wright considers that by photographing in red light we are able to penetrate through the atmosphere to the solid surface of Mars, while in violet light we secure only a picture of the atmosphere.

The radiometric measurements made at the Lowell and Mt. Wilson observatories tell us, at last, something about the temperature of Mars. Confidence in these observations is established by the facts that they show that there is more radiation from the equatorial than from the polar regions; more from the afternoon side (where the sun has been shining) than from the morning side; and that there was a gradual increase in radiation from the southern hemisphere with advancing summer. The interpretation of the results in terms of temperature involves, from a number of factors, considerable uncertainty, but reasonable assumptions indicate a temperature at noon on the equator of something like 10° C., and, therefore, well above the freezing point.

Nova Pictoris.—A bright nova in the southern constellation Pictor was discovered on May 25 by Watson, in South Africa. The story of the discovery has points of interest. Mr. Watson, who is an employee in the Postal and Telegraphic Department, was on his way to work a little before 6 A. M. when he noticed a bright star near α Pictoris which he did not recognize. On his return home for breakfast he looked up the star field in an atlas and found no bright star in that position. He felt sure that it was a nova and at once telegraphed to the Cape Observatory. The night of the 25th was clear and the astronomers at the observatory, by the prompt action of the discoverer, were able to obtain photographs of position, brightness, and spectrum of the nova at an early stage in its development. From the Cape the news was cabled to Copenhagen, whence, as usual, it was distributed all over the world to interested astronomers. Too far south for observation in the United States and Europe, it was persistently photographed and visually observed at the Cape Observatory, the Harvard station at Arequipa, Peru, and at the Observatory of La Plata, Argentina. Its former history was traced at the Harvard Observatory on plates taken at the southern station. It is apparently identical with a faint star which appears of constant magnitude 12.75 up to the end of 1924. Plates taken on January 4, 11 and 13, 1925, show no stars fainter than the eleventh magnitude and on these the star is not visible. On April 13, 1925, nearly two months before maximum light, the star was of the third magnitude. No photographs are available from then until the date of discovery. On May 25 the magnitude was 2.4. The brightness increased to magnitude 2.0 on June 4, to 1.5 on June 8, and reached its maximum, at magnitude 1.1, exceeded by that of only a few stars, on June 9. The increase in brightness was, thus, exceptionally slow. Most novæ make the entire rise in a few hours or days. The brightness decreased more rapidly than it increased, and, on the down grade, was subject to rapid and marked oscillations. While the changes in the spectrum followed, in general, the sequence peculiar to novæ, they, also, proceeded at a much more leisurely pace than usual.

The Interferometer.—The angular diameter of *o* Ceti (Mira, the Wonderful), at maximum brightness, in 1925, was successfully measured by Pease with the 2-foot interferometer attached to the 100-inch reflector of the Mt. Wilson Observatory. The angular diameter was found to be 0″.056, or about one-third greater than that of Betelgeuse, which, as will be remembered, was the first star measured with this instrument. In order to convert the angular diameter into linear diameter, the distance must be known. A very close companion of Mira renders the measurement of the distance rather uncertain, the photographic images of the two stars running together and making it difficult to bisect the image of Mira with a micrometer wire. The parallax is estimated as 0″.02. The linear diameter then comes out about 250 million miles, approximately the same as that of Betelgeuse, and considerably larger than that of the earth's orbit. Mira is a red giant of spectral type Me, and a long period variable. It was the first variable star discovered—by Fabricius in 1596—and its variations, from the second or even the first magnitude down to the eighth or ninth and up again in a period of 320 to 370 days, make it a very spectacular object. The presence of titanium oxide bands and of low temperature metallic lines indicate that it is a cool star. Also, Nicholson & Pettit's measures with the radiometer show that a large percentage of the radiation is heat. The irregularities in the period and range indicate that physical causes underlie the light variation. They suggest an accumulation of internal resistance to a point where there is a sudden release through an overlying resistance—perhaps in some measure analogous to the phenomena of sunspots.

The usefulness of the interferometer extends also to the measurement of double stars where the components are so close together as not to be readily separable with the eye. It has now been used with success in the observation of a spectroscopic binary. Mizar (ζ Ursæ Majoris) is a fine visual double. Pickering, in 1889, found that the spectral lines of the brighter component became alternately double and single and concluded that this component was itself double. From the method of discovery, such stars are known as spectroscopic binaries. The period of revolution of spectroscopic binary is about 20 days and 13 hours; the average distance between the two stars a little more than one-fifth an Astronomical Unit (the distance from the earth to the sun); and the distance of the system from the sun, 72 light years. The fact that Mizar is a member of the moving Ursa Major cluster has made it possible to determine the distance with considerable accuracy. By turning the interferometer beam carrying the two mirrors, as well as by varying the separation of the mirrors, Pease was able to find a position in which the fringes disappeared and thus to measure the direction of one star from the other and their apparent angular separation. The line of the stars changed its direction in four nights by 45°. It then became possible to deduce that the orbital plane is inclined 50° to the plane of the sky. The projected separation amounted to only one-eightieth of a second of arc—corresponding, however, at that distance to more than 25 million miles. A simple illustration will show what a big triumph this achievement is for the interferometer. The angular separation, which was measured, is the same as that of two lights one inch apart and observed from a distance of 250 miles.

Relativity.—Three reports of observations bearing on relativity have appeared. The first concerns the interference effects observed by Michelson and Gale between two beams of light travelling in opposite directions through a rectangular arrangement of pipes, 2,010 x 1,113 feet. The experiment was first tried in the open air but the interference fringes were too unsteady for accurate observation. The pipes were then laid with the joints carefully sealed, adjustable mirrors mounted at the corners, and the air exhausted to a pressure of one-half to one inch of mercury. The observed displacement agrees closely with that predicted as the effect of the rotation of the earth on the velocity of light both on the assumption of a fixed ether and in accordance with relativity.

D. C. Miller has carefully repeated at Mt. Wilson the famous Michelson and Morley experiment of dividing a beam of light into two parts and reflecting them back and forth over measured equal distances at right angles to each other. While the original experiment, made in Cleveland, near sea level, gave no evidence of a difference in time of transmission, the recent trial, at an altitude of about 1,700 meters, gives a positive result. Miller and Silberstein interpret this as meaning that the ether is gliding over the earth with a speed which varies from about zero at sea level to about six miles per second at the altitude of Mt. Wilson. Eddington contests this.

Finally, the work of Adams, on the spectrum of the companion of Sirius, has accorded additional evidence in support of relativity. According to this theory, a strong gravitational field slows down the atomic vibrations, with the result that the spectral lines from such a source are shifted relatively to lines produced in a weaker field, such as that of an arc light on the earth. Such a displacement, which Einstein pointed out to be one of the crucial tests, had already been reported by St. John in the spectrum of the sun. Sirius has a small companion star, invisible to the naked eye. In spite of its insignificant appearance, it must be nearly as massive as the sun, for it exerts a very considerable gravitational pull upon its brilliant companion. Its spectral type indicates that it is very hot and much brighter, area for area, than the sun. The low apparent brightness, then, must be attributed to small size. This conclusion leads to a value for density which is startlingly large and entirely inexplicable before Eddington's researches revealed the possibility that the atoms in the interior of a star, stripped of their electrons and reduced perhaps to one one-hundredth the size of terrestrial atoms, might be packed perhaps a million times more closely together before overcrowding causes the material to cease to act as a perfect gas. Eddington pointed out that surface gravity of this star should be such as to cause a shift of the lines about thirty times as great as the shift already detected in the spectrum of the sun. Adams photographed the spectrum with the great Mt. Wilson reflector and found the shift to be almost precisely as predicted, thus furnishing confirmation of Eddington's views and of the theory of relativity. This star, then, is only about 12,000 miles in diameter—slightly larger than the earth; its mass is nearly that of the sun, and its density over 50,000 times that of water. It is far denser than anything known on the earth: a pint of its substance would weigh twenty-five tons.

The Magellanic Clouds and the Spiral Nebulae.—The two Magellanic Clouds in the southern sky, looking like isolated patches of the Milky Way, have always excited much speculation. Their appearance alone justifies the conclusion that these apparently compact groupings are not due to a chance alignment of stars and nebulæ at very different distances from us, but, rather, that each Cloud is a physical system of stars all at very much the same enormous distance. Knowledge of the characteristics of any members of the system leads to valuable deductions concerning the entire cloud. These clouds contain a considerable number of stars which vary in brightness in a manner typified by the variation of the star δ Cephei. They are known as Cepheid variables. Miss Leavitt found, some twenty years ago, that in the Small Magellanic Cloud the brighter Cepheids have the longer periods of light variation; that, in fact, there exists an almost linear relation between apparent magnitude and logarithm of the period.

As these stars are, presumably, all at much the same distance, this relation becomes one between period and relative actual luminosity. The only thing lacking to make it possible to use this relation as a method of measuring great distances was a knowledge of the actual luminosity corresponding to a certain period. This difficulty was met by the determination of the distances of a considerable number of isolated Cepheids. Those of shortest period—from 3 to 24 hours—appear to be of median absolute magnitude (average of maximum and minimum brightness if at a distance of 10 parsecs) —0.2. They average about 100 times as bright as the sun. Cepheids of a mean period of seven days are about 700 times as luminous as the sun; while those of longest periods, forty days or over, appear to be as much as ten thousand times as bright as the sun. The development of the luminosity-period relation is largely due to Shapley, who has made use of it, on the assumption that Cepheids of a given period are much alike wherever found, in his determination of the distances and distribution of the globular clusters. The ingenuity and the powerfulness of this method of measuring distances far greater than those that can be determined by the methods of trigonometric measurement, parallactic motion and moving clusters, justifies the somewhat long outline which has been given.

To return: the parallax (the angle subtended at the object by the radius of the earth's orbit) of the Small Cloud is found to be about 0″.000032. The distance is thirty-one kiloparsecs, or about 101,000 light-years; that of the Large Cloud about 112,000. Now that the distance is known, the actual brightness of the stars and nebulæ may be determined from the apparent brightness, and the linear dimensions from the apparent (angular) dimensions. We can only briefly mention some of the more interesting results. They are subject to some corrections through the possible modification of some of the assumptions. The average angular diameter of the Small Cloud on photographs of twenty-three hours' exposure is 3°.6. The corresponding linear diameter is two kiloparsecs or sixty-five hundred light-years, which is equivalent to about fifty times the distance from the earth to the Hyades cluster in Taurus. The Large Cloud is more than twice as large. The Orion Nebula, which is visible to the naked eye, seems to be a very small affair compared with some of the gaseous nebulæ in the Clouds. The largest of all, 30 Doradus, would fill nearly the entire constellation of Orion.

At the distance of the Clouds, stars of the zero absolute magnitude (about 100 times as bright as the sun) are only of apparent magnitude seventeen and a half. It takes a telescope with a lens fully forty inches in diameter to show so faint a star. Many stars in the Clouds are much brighter than this. In the Small Cloud there are perhaps 300 stars brighter than absolute magnitude — 7, i.e., more than 55,000 times as bright as the sun—the brightest stars known; and about 260,000 stars brighter than absolute magnitude zero. The brightest stars are mainly red giants, the brightest variable stars having diameters of the order of 10^9 kilometers, and being, therefore, even larger than Betelgeuse and Antares. S Doradus, if, as seems probable, a member of the Large Cloud, must have a median absolute magnitude of —8.9 which makes it 600,000 times as bright as the sun. No other star of comparable brilliance is known unless it be one or two novæ at the crest of their outburst. The nebulæ in the Clouds are also very bright in comparison with those in other parts of the sky. This is to be expected on the theory that nebulæ are excited to radiation by neighboring stars.

Relations to Spiral Nebulae.—Shapley points out several suggestive comparisons between the Large Cloud and the spiral nebula Messier 33, the distance of which has recently been measured by Hubble (see below). Each contains one abnormally large and luminous gaseous nebula, comparable in size and brightness; the average diameter (4.3 kiloparsecs) of the Cloud is very closely the same as the greatest diameter (4.5 kiloparsecs) of the spiral; the integrated absolute magnitude of M 33 is approximately —15, while that of the Large Cloud lies between —15 and —17. The average diameter (15 parsecs) of the brighter star clusters in the Large Cloud is three times the average diameter (5 parsecs) of the hundreds of nuclei in M 33; the nebulæ in the Large Cloud, excluding 30 Doradus, average about 7 parsecs in diameter, and those in the Small Cloud about 5 parsecs. These two classes of objects in the Clouds average considerably brighter than do the secondary nuclei of the spiral. While it is difficult to trace any spiral structure in the Clouds, these analogies between the Clouds and a typical spiral nebula seem to Shapley to indicate that a study of the individual stars, clusters and nebulæ in the Magellanic Clouds is a valuable approach to the study of the far more distant spiral nebulæ.

The nature of the spiral nebulæ has long been a subject of animated discussion. They are exceedingly numerous—several hundred thousand are estimated to be within photographic reach of a 60-inch reflector with an hour's exposure—and they range in size from the mighty Andromeda nebula (Messier 31), which is visible to the naked eye, to tiny little specks on the photographic plate whose spiral structure is barely recognizable. In their distribution they avoid the region of the Milky Way and are particularly numerous near the north galactic pole. The radial velocities appear to be very large, and, with few exceptions, they are velocities of recession. Several have been found to be moving away from us at velocities greater than 1,000 km./sec. Rotation has been detected in some spirals by spectrographic observation of the outlying regions. Van Maanen, by comparison of plates taken at different times, has detected motion, during the interval, of many of the knots and condensations. Attempts to measure their distance by the ordinary method of triangulation have proved unsuccessful. Many faint novæ have appeared in the Andromeda Nebula during the past few years when careful watch for them has been kept. A rough estimate of the distance of the nebula can be made on the assumption that such novæ are comparable in actual brightness with the novæ which appear in the Milky Way. Such estimates run as high as a half-million light-years.

It is apparent that the whole question, whether a spiral nebula is an "island universe" composed of millions of stars, clusters, and nebulæ, or some kind of an aggregation of moderate size, hinges on the question of distance. Added to the puzzling evidence was the fact that these objects have a nebulous appearance, which no one had been able to resolve into discrete star-like images. One-half of the annual prize for noteworthy contributions to science was awarded at the Washington meeting of the A. A. A. S. to Hubble, of the Mt. Wilson Observatory, for a paper entitled "Cepheids in Spiral Nebulæ." With the two large reflectors he has been able to resolve, photographically, the hazy outer regions of the Andromeda Nebula (M 31) and of M 33, in Triangulum, into dense swarms of images in no way differing from ordinary star images. A long series of plates furnishes evidence that there are many stars which have a typical Cepheid type of light variation. Owing to the extreme faintness of the stars at minimum light, it proved advisable to apply the period-luminosity law, developed by Shapley (see above), to maximum brightness. The small dispersion of the results showed that this procedure was justified. The distances of both nebulæ are found to be 285,000 parsecs, or 930,000 light years! Variables have been found in several other spirals, but not enough plates have yet been collected for their study. The spiral nebulæ, or at least some of them, then, are vast systems far outside the galactic system. Whether they are all very much alike, and those that appear very small are many times as far away as the Andromeda Nebula, we still have no way of knowing. The diverse appearance of the larger ones indicates that they do differ markedly in size and density.

Atomic Theory and Stellar Constitution.—The recent developments in atomic theory have proved of enormous importance to astronomy, in the interpretation of solar and stellar spectra. It now appears that each spectral line is to be attributed to emission (or absorption) taking place in connection with the transition of an atom (or molecule) from one definite, specifiable state to another, and that the number of light-waves per second is exactly proportional to the change in energy. A great deal of work has been done on the spectra of many elements, such that the changes of state corresponding to nearly all important lines in stellar spectra are now understood.

In the atmospheres of the relatively cool stars, the atoms are nearly all at the lowest energy level and are capable of absorbing certain lines, but not all. At higher temperatures a larger number of atoms are in higher states, and, in their transitions, are capable of absorbing a different set of lines. The latter are conspicuous at the temperature of the electric arc, while the former are prominent in spectra produced in the electric furnace at low temperature. Their characteristic strengthening in sun-spots, which was attributed years ago to the lower temperature of sun-spots, now finds complete physical explanation. The low temperature lines of the unexcited atoms are also strong in the spectra of the coolest stars.

The atom, if sufficiently excited, loses one electron, becoming an ionized atom characterized by new energy states and capable of absorbing or emitting entirely different sets of lines. Such lines have long been known as enhanced lines. They are produced at the high temperatures of the spark, some appearing with less excitation, others requiring more. When more than one electron has been removed, the lines are usually far in the ultra-violet and entirely inaccessible in stellar spectra, but certain elements, such as Silicon, give lines, in several successive stages of ionization, which lie in the visible spectrum.

In the atmospheres of stars, ionization is favored both by high temperature, tending to make the electrons fly off, and by low pressure, diminishing the opportunity for an ionized atom to pick up an electron.

In the sun's atmosphere, at temperatures of 5,000° to 6,000°, the elements of easy ionization are almost completely ionized. In the extreme cases of Lithium and Rhubidium the lines do not show at all in the ordinary solar spectrum, but they do appear in the spot spectrum, where the lower temperature permits some neutral atoms to exist. In general, the arc lines (neutral atom) tend to be strengthened in spot spectra, while the enhanced lines (ionized atom) tend to be weakened. Almost every detail of the difference between the spectrum of sun-spots and that of the rest of the sun can now be explained.

In the upper atmosphere (the chromosphere) of the sun, the pressure is much less than it is in the lower atmosphere. There are, therefore, fewer neutral and more ionized atoms there: the enhanced lines are relatively strong in spite of the lower temperature. Thus simply is explained a phenomenon which has been very puzzling for generations. This explanation receives additional support from recent studies of the pressure in the sun's atmosphere and its opacity. Where the gas of the sun's atmosphere has a density as great as one one-thousandth that of ordinary air, various processes render it slightly opaque or hazy and there the sun, although purely gaseous, appears to have a surface (called the photosphere), revealing definite markings corresponding to the hotter and cooler regions. Stewart and Russell estimate that a pressure of one one-hundredth of an atmosphere is sufficient to produce this effect. Milne, from additional evidence, makes it one ten-thousandth. According to the latter figure, the whole quantity of gas in the sun's atmosphere above the photosphere appears to be no greater than that in a layer of air only a few inches thick. Laboratory evidence, also, is to the effect that this quantity of material is abundantly sufficient to absorb spectral lines. Since the sun's atmosphere (the chromosphere) is several hundred miles in depth, its density must be excessively small. There is good evidence that radiation pressure nearly neutralizes solar gravity in the chromosphere and permits of this considerable depth.

Spectra of Stars.—The same principles applied to the spectra of stars and with equally suggestive results. Take, for example, the spectrum of Silicon, the atom of which in its neutral state, has four electrons outside the "complete shell"; the lines due to neutral Silicon appear in the spectra of the sun and of the stars which are known to have a low temperature; those due to Si+ (Silicon atoms which have lost one electron) are observed in stars like Sirius; still hotter stars show the lines of atoms which have lost two electrons; and in the very hottest stars is found evidence of Silicon atoms which have lost three. In general, the hotter stars show the lines of ionized atoms. The lines of metals appear at lower temperatures than do those of the permanent gases, such as Oxygen and Nitrogen, which are harder to ionize. As the temperatures can be found from the color of the stars and from the distribution of their radiation, it is possible, since the degree of ionization also depends upon pressure, to use the observational data concerning line intensities to determine the pressure in stellar atmospheres. Miss Payne finds that the pressures range from one ten-thousandth of an atmosphere in the lower layers to about one-millionth of an atmosphere in the upper layers. The stars are pretty sharply divided into "giants," of low density, enormous size and great luminosity, and "dwarfs," which are relatively more dense, smaller and not so bright. The giant stars, with their comparatively low density and small force of gravity at the surface, are believed to have much less dense atmospheres than the dwarfs possess. This difference may readily account for the greater strength, in the giants, of certain enhanced lines and, in the dwarfs, of certain lines of neutral atoms, and thus give physical meaning to the method devised by Adams some years ago to determine, from the relative strength of certain lines in their spectra, the absolute brightness of stars and hence, by comparison with their apparent brightness, the distance.

We have also advanced far toward an understanding of the conditions which prevail in the deep interior of a star. Here ionization must be much more nearly complete, many of the atoms being stripped down to bare nuclei, which, together with the free electrons, form a mixture of so low a mean molecular weight, that, in spite of the great pressure, it behaves as a gas. Equilibrium in the stars is thought to be of the radiation type—the change in temperature from point to point is determined from the rate at which heat flows out to the surface. It has now become possible to calculate the opacity (roughly, the resistance to the flow of heat) of the material, and so to develop a theory of the internal condition of the stars.

Eddington and Jeans, while disagreeing on certain technical matters, agree in concluding that the brightness should depend mainly on the total mass and relatively little on the surface temperature of the star—a conclusion which is in excellent agreement with observation. The theory predicts the relative brightness of stars with satisfactory accuracy, but gives too high an absolute brightness. This disagreement between theory and fact may be removed by further work. According to Eddington, the density at the center is about twenty times the mean density throughout the star, and the central temperature ranges from about one million degrees centigrade for the huge red stars, such as Antares, to about thirty million for a large proportion of the stars, of very different characteristics, such as the Orion stars, Sirius, the Sun and the faint red stars typified by 61 Cygni. The white dwarfs, such as the companion of Sirius (see later) probably have central temperatures of more than one hundred million degrees.

Evolution of the Stars.—These results cause modification of the older theory (*Year Book*, 1914, p. 590) of stellar evolution; in particular they necessitate the abandonment of the assumption of a fall in the internal temperature in the denser dwarf stars in consequence of the close-packing of the atoms. There is now reason to ascribe the low surface temperature of these stars, not to a low central temperature, but to the greater opacity with greater density, which prevents the heat from leaking out to the surface. There is good geological evidence that the radiation of the sun has changed very little in the past billion years. The life of a star must be many times as long. The secret of the maintenance of radiation throughout this great length of time appears to lie in the equivalence of matter and energy. Present investigators are agreed that a consistent theory of stellar evolution can only be built up by assuming that a very considerable part of the material of a star is gradually transformed into energy and radiated away into space.

Russell finds it necessary to conclude that rate of transformation of matter depends upon the temperature. He suggests that at some critical temperature, in the neighborhood of a million degrees, the degradation of some form of matter begins, thus supplying the radiation of the giant stars of large diameter and low central temperature; that at a temperature of about thirty million degrees processes come into play which start the gradual transformation into heat of the main mass of the star. During this part of its evolution the star maintains a nearly constant central temperature, steadily decreases in mass, increases in density and opaqueness and passes down the main sequence represented by Sirius, the Sun and the small faint red stars. Finally, the white dwarfs, such as the companion of Sirius, may be brought into the orderly sequence of evolution by the assumption that, after the transformation of the main mass, there remains only a highly refractory material which is only transformable at still higher temperatures. If, after the transformation of the main mass, the star is still of considerable size, it continues to contract to greater density, grows hotter and brighter until this final transformation sets in. In such discussions the use of familiar measures of time involves numbers which are inconveniently large. Smart suggests the use of the "Cosmogonic Unit" of 7.7×10^{12} years, which he finds to be the interval required for a star to pass from an infinitely large mass to the present-day mass of the sun. The life history of a star probably extends over a large number of these units.

SELECT REFERENCES ON ASTRONOMY

The following list includes books that were published previous to the present year, but which are still the most recent in their fields. The most recent material of all is to be found, of course, in the journals: such as the *Astrophysical Journal;* the Publications of the Astron. Soc. of the Pacific; Monthly Notices of the Royal Astron. Soc., and *Astronomische Nachrichten.*

Jones, H. Spencer, *General Astronomy.* (N. Y., Longmans, Green, 1922.)—The most recent book covering the general field of astronomy. A satisfactory textbook for the college student and a book that, in its exclusion of mathematics, is pleasant reading for the amateur.

PHILLIPS, Rev. T. E. R., and STEAVENSON, Dr. W. H., assisted by others, *The Splendour of the Heavens.* (2 Vols., London, Hutchinson, 1923.)—These two volumes were brought out in twenty-four fortnightly parts written by various authorities. A popular book of descriptive astronomy. Over 1,000 illustrations, averaging more than a picture to a page. Of particular value to those who give popular lectures.

LEWIS, Isabel M., *A Hand-Book of Solar Eclipses.* (N. Y., Duffield, 1924.)—A book of 118 pages dealing with the phenomena of total eclipses of the sun and evidently timed to meet the popular interest excited by the eclipse of January 24, 1925.

DINGLE, Herbert, *Modern Astrophysics.* (London, Collins Sons, 1924.) —An up-to-date account of modern astrophysical discoveries and theories. In the preface the author says: "While the popular appeal has been given first place, difficulties have not been evaded. It has been assumed here that the reader is prepared to think. No specialized knowledge is required."

MITCHELL, S. A., *Eclipses of the Sun.* (2d ed., N. Y., Columbia University Press, 1924.)—An account of the observation of eclipses; what they have contributed to our knowledge of the constitution of the sun; the eclipse test of relativity; and what remains to be done in the future. It is very well illustrated, and many of the experiences of the author on eclipse expeditions in which he took part are interestingly recounted.

OLIVIER, Charles P., *Meteors.* (Baltimore, Williams and Wilkins Co., 1925.)—A general work on meteoric astronomy written by the leading authority on meteors in this country. Detailed methods of observation and computation are given and the results discussed. The literature of the subject is thoroughly reviewed. The author's own opinions are frankly stated.

RIGGE, William F., *The Graphic Construction of Eclipses and Occultations.* (Chicago, Loyola University Press, 1924.)—The author has long been interested in the representation, by graphs, of the circumstances of eclipses. Many of his diagrams have appeared in *Popular Astronomy.* There are also chapters on graphic methods of determining the times of rising of the sun, moon and stars, and hints on drawing and computing.

PAYNE, Cecilia H., *Stellar Atmospheres.* (Cambridge, Harvard College Observatory, 1925.)—The first of a series of research monographs to be issued from the Harvard Observatory. An analysis of stellar atmospheres by means of modern theories of atomic structure and ionization. Necessarily technical.

JEFFREYS, Harold, *The Earth: Its Origin, History, and Physical Constitution.* (Cambridge University Press, 1924.)—The content of this scholarly work is perhaps sufficiently indicated by the title. One reviewer says: "*The Earth* is emphatically not a book to be read through from cover to cover as one would read an essay. Nor is this, even principally, due to the mathematics which enters into it, for the text is full of close reasoning. We take it to be a compliment to a book to say that the digestion of it should only be undertaken in doses, and these when the mental state is pretty vigorous."

DIVISION XXIX
ENGINEERING AND CONSTRUCTION

CIVIL ENGINEERING

By John M. Goodell
Civil Engineer, New York

Steel Bridges.—The outstanding feature of the steel-bridge field in 1925 has been the highly technical matter of the loads which it is safe to place on existing bridges. Almost as interesting although not so important from an engineering viewpoint has been the unexpected revival of the determination of the better public policy, tolls or bonds, in financing very expensive bridge projects, a subject which was believed to have been settled in favor of bonds, until very recently, for all public bridges.

Stresses on Railway Bridges.—The safe loading of railway bridges seems to be easily settled. They have all been designed by experts using approved unit stresses for their tension members, columns and other parts. Nominally, their safe load is that for which they were designed. Railway engineers are human, however, with a strong desire to have a substantial anchor to windward in matters where trouble may arise. They knew by experience that getting appropriations for heavier bridges from their directors is far from easy. They have also known for a long time that the standard unit stresses for structural steel, adopted when the material was less uniform and reliable than it is to day, were very low, but they have said nothing. These low unit stresses used in their designs were their safeguard when operating officials insisted on loading bridges beyond their nominal capacity and directors could not see how to spare money for stronger bridges.

In 1922, however, the subject of unit stresses in steel for buildings became so important that the American Society of Civil Engineers appointed a committee to investigate it. The committee reported in January, 1925, and this report is still, at the close of the year, a subject of animated discussion. So far as it relates to bridges, the conclusion reached from a consideration of the experience with existing bridges was that an increase in working unit stresses is justified, provided the steel is of standard quality, the designing is properly done and the workmanship is good. This conclusion has, naturally, drawn attention to the determination of the actual strength of old bridges, and in December the public discussion of the subject was started with a highly technical paper presented to the American Society of Civil Engineers.

Toll Bridges.—Turning to public toll bridges, the other major subject in the field of steel bridges, the public seems now to be where it was about forty years ago, floundering in uncertainty. Then, as now, there was a feeling that the only way in which money could be raised for very costly bridges was to meet at least a part of their cost by tolls, much as such charges were disliked. During later years tolls became so unpopular for public bridges that they were repealed quite generally. Since the World War, with all the demands for public works, tolls have again become fairly common. The suspension bridge across the Hudson River was built by a private company and tolls are charged for using it, but it is safe to say that had the New York Highway Department had funds for this structure it, also, would have made the Bear Mountain bridge a toll bridge. The Delaware River bridge between Philadelphia and Camden was made a toll bridge by the acts of the legislatures of New Jersey and Pennsylvania authorizing the building of the structure. The governor of Pennsylvania has recently insisted that the bridge shall be free when it is opened in 1926 and his controversy with the New Jersey authorities on this subject was proceeding briskly when 1925 ended.

The question involved is the very old one of whether one of these large structures is of sufficient importance to a whole community to pay for it by a bond issue, or is only useful to those who pass over it and are accordingly charged tolls for the privilege. With a bond issue, all taxpayers contribute annually to pay the interest, sinking fund and maintenance charges. With tolls, only those using the bridge pay any of the charges.

The mixture of opinion on the subject is shown by the condition of interborough communication in New York. The Brooklyn bridge was operated as a toll structure for many years, but it was finally made free on the ground that it was essential to the welfare of all Manhattan and Brooklyn. This policy was followed with the later bridges between Manhattan and Long Island. On the other hand, Manhattan is connected with the Borough of Richmond (Staten Island) by a ferry, formerly privately owned but now operated by the city, on which fares have always been charged, even under the city's control, although it serves exactly the same purpose as the four free public bridges over the East River.

Bridge Projects.—Few bridges of even moderate importance were completed in 1925. The Delaware River bridge, already mentioned, had its last wires for the cables put in place in January and the stiffening trusses were closed in May. It is a suspension structure with a main span of 1,750 ft. and side spans of 719 ft., being longer than any of the East River bridges at New York. It was the longest span under construction in 1925. About eighteen miles north of Oakland, Calif., another large bridge is under construction across Carquinez Strait, an arm of San Francisco Bay, by the American Toll Bridge Co. It has two 1,100-ft. cantilever spans, a central tower span of 150 ft., and two 500-ft. anchor spans, with a viaduct 1,152 ft. long at one end.

Several important bridge projects made a start during the year. The most important is the so-called Strauss project, tentatively approved during 1925, for a bridge crossing the Golden Gate at San Francisco with a 4,000-ft. main span 200 ft. above the water level and two 1,345-ft. approach spans.

The legislatures of New York and New Jersey have appropriated funds for a preliminary study by the Port of New York Authority for a bridge across the Hudson River from a point between 170th and 185th Streets, Manhattan, to Fort Lee, N. J. No information about the proposed structure has been made public as yet, but its magnitude is evident from the fact that an unofficial study of a bridge at this site called for a center span of 3,400 ft.

Contracts were let during the year for a large part of the work on the Montreal bridge across the St. Lawrence. It will have a cantilever span of 1,097 ft. and a long steel approach on the south side.

Construction was begun on a structure interesting from an artistic viewpoint, although its main span is only 670 ft. long. This is the new Point Bridge at Pittsburgh. The lower chord will be curved upward strongly, giving the structure, which is a cantilever, an attractive arch-like appearance. So far as artistic effect is concerned, however, the Arlington Memorial Bridge across the Potomac River at Washington is considered likely to be one of the most notable examples of what engineers and architects working together can accomplish. Congress appropriated $14,000,000 for the structure and work on the plans was begun in 1925.

A contract for the steelwork, 8,750

tons, for the Peace Bridge across the Niagara River between Buffalo and Fort Erie, Ont., was placed in November. This will be an important international structure.

Steel Buildings.—While there were no notably novel steel buildings constructed in 1925, structural steel has witnessed two important developments. One is a controversy over unit stresses in steel in buildings and the other an enforced change in detailing due to the zoning laws in some cities.

In January, a committee of the American Society of Civil Engineers reported that the unit stresses permitted for steel by the building laws of many cities were too low. These stresses have been based for many years on 16,000 lbs. per square inch in tension and bending, although a few cities recently raised that limit to 18,000 lbs. Many industrial buildings in places where they were not subject to building-code requirements have been designed of late on the basis of 18,000 to 22,000 lbs. Examinations of these structures by the committee showed that their behavior in service was satisfactory. Much older structures which, owing to imperfect assumptions in their design, have been in service with unit stresses up to 20,000 lbs. for many years showed similarly satisfactory behavior. A quarter century of progress in steel making, concurrent developments in steel design and long experience with structures stressed beyond the 16,000-lb. limit fixed in most building codes, all indicate that this limit throws an unnecessary hardship on those paying for such buildings.

While the committee found no evidence that any of the instances of faulty performance of steel in buildings was due to high working stresses, it admitted that other faults had occurred and attributed them mainly to unskillful design of the general structural system, crude details and insufficiency of bracing. In other words, poor engineering rather than poor materials was held responsible for such troubles as have been found. The use of low unit stresses, the committee believed, was no assurance that lack of skill in designing or poor workmanship or both will not result in defective structures. Further, the committee reported that engineering knowledge is now so advanced that future loadings can be much more accurately determined than formerly, and it is unnecessary to employ low unit stresses in order to provide for unexpected loads that may occur later.

Factor of Safety.—The progress of engineering is well illustrated by the gradual dropping of the term "factor of safety" in steel design. About the time 16,000 lbs. was adopted as the standard unit stress for steel, such a stress was based on the ultimate strength of steel, the smallest load which causes complete failure. Since that date, some twenty-five years ago, there has been a gradual change toward considering the elastic limit, or load at which steel first becomes permanently distorted, as its most significant property and to compare working stresses with it.

The ultimate strength of acceptable structural steel is 55,000 to 65,000 lbs. and its elastic limit is at least half of the ultimate strength, in no case being less than 30,000 lbs. Years ago it was the general practice to divide the ultimate strength by four or some other number, which was called the "factor of safety," to obtain the safe working stress for the steel then used. At that time this factor was an insurance against ignorance, poor design and inferior materials. But testing technic, engineering knowledge and steel making have all progressed since then; and today the competent engineer has little use for ultimate strength except as a general check on the properties of the materials he uses. There is no longer any need for factors of safety, therefore, and instead the engineer fixes his unit stresses on the elastic limit, which averages 36,500 lbs., with very few samples below 32,000 lbs.

The problem is to determine what percentage of the elastic limit shall be taken as the working stress. The records of tests of about six thousand heats of steel indicate to the committee that a very conservative estimate of the elastic limit would be 30,000 lbs. In other words structural steel will not suffer until it is loaded with 30,000 lbs. per square inch in tension. Provision must be made, however, for loads due to excessive crowds, the vibration of machinery and wind pressure during gales. These occur only occasionally and it is difficult to calculate the secondary stresses due to the distortion they cause. But experience with existing structures satisfies the committee that perfect safety is assured if two-thirds of their conservative assumption of the elastic limit is taken as the safe working stress. In other words, structural steel can be used to carry a load of 20,000 lbs. in tension with complete assurance that there is a margin of strength adequate to take care of any rare, unexpected loads which may or may not be imposed on the structure.

Assumptions concerning the safe working stresses in columns are on a somewhat different basis than those regarding stresses in tension, because knowledge of the behavior of steel structural members under compression is not so definite as is the case with tension. A special committee of the American Society of Civil Engineers has been working for some years to gain more information on the subject, and until its final report is made it is believed that a unit working stress of 16,000 lbs. is permissible for columns having a ratio of length to radius of gyration (l/r) of less than 50. For longer columns, it is recommended that the working stress be taken as 16,000—80 E, where E is the excess of l/r above 50.

Building Codes.—The public discussion of this report during 1925 indicated little difference of opinion with its recommendations provided the engineering and inspection are in competent hands. There is an apprehension among some structural engineers, however, that trouble may arise through the use of poor untested steel such as reached the country in 1925 from Europe, through changes in the method of determining the elastic limit, and particularly through poor engineering and workmanship. For this reason these cautious critics believe the committee should have been satisfied to recommend 18,000 lbs. for tension and bending and 15,000 lbs. for short columns for the present.

These critics are really endeavoring to strengthen the police powers of our communities, as codified in building regulations and laws requiring the registration of architects and engineers, by making it illegal for competent engineers to serve their clients most economically, because precedents may thus be made which incompetent engineers will employ dangerously. Building codes are troublesome things to draft satisfactorily, and even more difficult to enforce. A special committee appointed by Secretary Hoover has been endeavoring since 1921 to prepare a model building code, but only tentative drafts have been put out as yet. It is not intended to recommend a uniform building law for use throughout the country; indeed, specialists in the subject seem to consider such an endeavor both undesirable and impracticable. What the committee is aiming to furnish is a model upon which a code suitable for any city can be fashioned.

The real issue involved, which has not yet been discussed except informally, is whether it is good public policy to permit competent engineers to use working stresses which are admittedly safe in their hands or to compel them by law to use lower stresses, increasing thereby the cost of buildings to owners, in the hope that incompetent engineers and poor workmen who succeed in carrying on their callings in spite of building codes and registration laws will have fewer opportunities to erect dangerous steel buildings.

Set-back Building System.—The effect of some zoning laws on high building construction is due to their requirement that after a building reaches a specified height its outside walls must be stepped back, so as to give more space through which sunlight will reach the streets and other areas below. Prior to the passage of such laws, the exterior walls were carried up continuously, from bottom to top, with only such modifications as the taste of architect and owner introduced. In such buildings it was endeavored to make the columns continuous from their foundations to the roof, not only on account of the economy of such construction but also because of the facility with which bracing could be provided to meet the stresses caused by wind loads, the vibration of machinery and such special loads.

Setting back the outside walls in conformity with zoning laws, as shown in the new building of the New York Telephone Co. in New York, introduces special problems in foundation loads, column loads and girders. They can all be solved by the application of well-established engineering knowledge, but they have been so unusual in building design heretofore that the rapid and sudden increase in their number has caused surprise in cities where this result of zoning laws is now just becoming evident.

Notable Steel Buildings.—Of the recent steel buildings, probably the telephone building just mentioned is the most interesting. The technical needs of a great telephone exchange placed a number of unusual requirements on the architects and engineers. Official information about them was not given out in 1925, as the building was not ready for occupancy in that year.

Another steel structure that is unusual is the Tribune Tower Building in Chicago, rising thirty-four stories above the level of Michigan Avenue and descending six stories below it. The very strong wind bracing of the steel frame is an unusual feature.

Plain and Reinforced Concrete.—During 1925 the most interesting item in the field of plain and reinforced concrete was the discussion of the report of the Joint Committee on Standard Specifications for Concrete and Reinforced Concrete. The committee was formed in 1919 by delegates from the American Society of Civil Engineers, American Society for Testing Materials, American Railway Engineering Association, American Concrete Institute and Portland Cement Association. In 1921 it submitted to these societies a tentative report which was discussed for about two years. During this period investigations were made by the committee to determine whether various procedures they specified were entirely practicable in the field. A final report was made in August, 1924, and this has since been under discussion. When the report was submitted the committee had twenty-three members, all prominent for years in some branch of cement or concrete work. There was no dissenting vote on the adoption of the report but one member refrained from voting.

In spite of the long time spent in the preparation of this document, the standing of those who prepared it and its practically unanimous approval by the committee, it is being criticized by other specialists, generally on the ground that it is difficult to understand just what some of the clauses require. This is not surprising when it is recalled that concrete is the only building material in general use which is manufactured on the site, not in shops; and reinforced concrete is still so youthful that a description of certain details may be perfectly clear to one set of specialists familiar with them and still be far less clear to other specialists without that familiarity.

Varieties of Concrete.—Another characteristic of the concrete field in 1925 was the marked extension of recognition by both engineers and contractors of the practicability and necessity of controlling the quality of concrete for different classes of work. For several years the Structural Materials Laboratory at Lewis Institute, in Chicago, and the U. S. Bureau of Standards have been publishing information on this subject; 1925 saw this information widely applied for the first time on many kinds of work. The adoption of the inundation method of measuring sand should be mentioned particularly, because it was in 1925 that it was first extensively used although it was brought out several years earlier. Another significant feature of the year's work was the rapid increase in favor of the use of pre-mixed concrete, and a considerable number of plants to produce this material were built.

So much concrete work has been done for several years under rigid inspection and in the face of increasing severity of competition that a larger number of skilled workers in concrete are now available than ever before. Largely as a result of this, there has been a decided decrease in the seasonal character of concrete construction and a marked increase in the speed of work. For example, the Bradley Apartments on Cedar Street, Chicago, a twelve-story structure, had the frame placed in one month.

The decorative possibilities of concrete are gradually being recognized by architects and during 1925 some interesting examples of this were produced, particularly the Parthenon at Nashville and the new buildings of the Louisiana State University.

Notable Concrete Structures.—The scientific side of concrete construction in 1925 is mainly noteworthy for the gratifying progress in the projected construction and testing in various ways of a large multiple-arch dam in California. The proposed tests will be of progressively increasing severity until the structure is destroyed. They are being worked out carefully, for this will be one of the most expensive and elaborate full-size tests in the history of engineering.

Of the structures finished or substantially finished in 1925 mention may be made of the following:

The Chicago Produce Market comprises six blocks of three-story and basement buildings, each block 82 ft. deep and varying from 576 to 813 ft. in length. The contract was let in January, 1925. The first building was completed within six months and all of them within nine months.

The Northern Ontario Building in Toronto, Ontario, sixteen stories high, said to be the highest building in the British Empire, although this assertion seems exaggerated in view of the height, 360 ft., of St. Paul's in London.

The Pittsburgh University Stadium of elliptical shape with the long axis 791 ft. and the short axis 607 ft. will seat 70,000 persons. It is built on a hillside. Many of the seats are reinforced concrete slabs resting on the ground and the remainder are much lighter slabs carried by steel framework. The daughter of the chief engineer acted as the architect for this structure, being a graduate in architectural engineering of the Ohio State University.

The double-deck street work on South Water Street, Chicago, will closely approach those ideals of transportation enthusiasts who wish to have roadways and sidewalks tiered one above the other on the same right-of-way. It is being executed largely in reinforced concrete.

The bridges of reinforced concrete substantially built in 1925 include the very attractive Fort Snelling-Mendota bridge near Minneapolis, with beautiful concrete arches, and the Four-Mile Causeway at Miami, Fla., with fifty-five girders having a graceful arch effect.

ELECTRICAL ENGINEERING

By Charles W. Weyl

Moore School of Electrical Engineering, University of Pennsylvania

---

GROWTH AND TENDENCIES

General Conditions.—The electrical industry has had an excellent year. The electric power demand of the country continues to increase at a rate which requires doubling of the power supply every five years. It is interesting to note, that due to improved economies, the cost of electricity to the consumer has decreased over 8 per cent. since 1914 despite a 20 per cent. increase in central station wages. Compare this, for example, with the 74 per cent. increase in clothing costs and the 42 per cent. increase in the cost of foodstuffs, over the same period. During the last year the average cost of electrical machinery has remained the same. Enormous increases in efficiency have been made in recent years, due in part to the use of larger units, cheaper fuels, increased thermal efficiencies, improvement of load factors by interconnections and other means, and by the rigid enforcement of the power factor clause.

Hydroelectric development has been slow in the past year, and although there are still some millions of undeveloped water horse-power in the United States, it is interesting to note that, if the entire available water power supply in this country were utilized, it would furnish less than half of the present total power demand. It is predicted that a rapid development of Muscle Shoals by private interests will take place. There has been much argument in recent years concerning super-power. These projects have, however, become so involved in political intrigue that both capitalists and engineers have preferred not to concern themselves actively with them.

The various technical societies are carrying on their important activities, and this year a new edition of the American Institute of Electrical Engineers Standards is being issued, involving a complete change in the form of publication, and many changes and additions in the subject matter. Possibly the most important addition is to be found in the classification of the usual operating conditions of machinery as well as standard test conditions, since the user of electrical machinery is more interested in the comparative performance of the machinery under operating conditions than under the special conditions of test.

Research Laboratories.—Since the war the development of the thermionic vacuum tube has been extraordinary. Even outside of the field of communication its uses are manifold. As a result of the perfection of the photo-electric cell and the electric filter, new apparatus and methods such as the Audiometer, Telephotography and many others described in the following report are now available. All of the large electrical manufacturing companies and many of the smaller organizations are maintaining excellent research laboratories. Most engineers are now of the opinion that industrial supremacy will in the future lie with those companies who realize the importance of their research departments. It is further interesting to note that in some of the largest industrial laboratories, a large proportion of the research is on pure science, without thought of direct commercial application. In the past year or two there has been an almost complete change in policy with respect to the findings in commercial laboratories. Whereas in the past, such material was kept as the confidential property of the company, now a very large part of the new scientific discoveries are made available to the entire profession. The United States Bureau of Standards continues its excellent work of research, standardization and coördination.

POWER

Status.—More power is produced in the United States than elsewhere in the world. The aggregate capitalization of the power industry in the United States was $6,600,000,000 as of January 1, 1925, compared with $5,800,000,000 in January, 1924. The gross annual revenue of the central station industry for 1925 is estimated at $1,500,000,000. It is estimated that the total energy output developed by power and lighting central stations will reach 60,000,000,000 kw.-hrs. this year. In May, for example, the total generation was 4,808,333,000 kw.-hrs. which showed an increase nearly 8.9 per cent. over May, 1924.

At the present time the capacity of stationary power generating units in the United States is approximately 50,000,000 horse power, of which 10,000,000 horse power is produced by water power. Approximately 90 per cent. of the population of the United States is supplied with electric service. It is further estimated that there are 350,000 employees in the power and light industry. January 1, 1925 showed that there were 16,555,714 light and power customers which indicated an increase of 2,178,283 customers during 1924, of which over 1,700,000 were domestic lighting, approximately 300,000 commercial lighting customers and 63,000 power customers.

Light and Power.—The United States Census Bureau, in a recent census of manufacturers embracing more than 275,000 industrial plants in this country, found that the combined cost for maximum power and fuel for heat used in manufacturing processes averaged 2.8 per cent. of the cost of the finished product. Records show that the United States has approximately 5,900 electric light and power companies. The privately owned systems serve nearly 16,000 communities and the publicly owned plants serve 3,000. The distribution of central stations according to output is as follows: stations of more than 50,000 kv-a; 95 in 1924—85 in 1922; 68 in 1924—and 44 in 1922; stations under 25,000 but over 500 kv-a; in 1924 3,073, and 2,321 in 1922. Practically 70 per cent. of the total power generated in central stations is generated by stations having more than 50,000 kv-a rating. Most of the large stations are found in the east north central states and the small stations in the west north central states.

Inter-Company Business. — There has been a great increase in inter-connections between power companies. The last two years has shown a 26 per cent. increase in inter-company business in this country. In the third Paris Conference on high-tension systems held in June this year, inter-connections of central stations and systems was one of the most discussed questions. In this country there have been some interesting applications of inter-connection between systems having different frequencies, and in one instance a 40,000 kw. frequency-converter was installed, inter-connecting a 25 and a 60 cycle system. This unit is controlled by what is known as the Scherbius load regulator and shows an over-all efficiency of 96 per cent.

Cost and Efficiency.—It is interesting to note the change in the cost of central stations between 1914 and 1925. The average cost per kw. was $60 immediately preceding the war as against $115 at the present time. A remarkable gain of 20 per cent. in thermal efficiency realized in the last year was due to air-heaters, reheating, stage bleeding, water-cooled furnaces and pulverized fuel equipment. It is important to note that very little improvement in efficiency has been made in transmission and distribution and that more than 30 per cent. of the total energy is lost in such systems. On the average, fuel cost represents about 30 per cent. of the switchboard energy cost. At the present time more than twenty American stations are producing a kw.-hr. on one pound of coal. A striking example of the increased fuel economy is found in the fact that the coal consumption in Pennsylvania increased from 5,060,000 tons in 1919 to 5,276,000 tons in 1924, while the electric output increased from 3,070,000,000 kw.-hrs. to 5,029,000,000 kw.-hrs. in other words, a 63 per cent. increase in power output involved less than 4 per cent. increase in fuel consumption. In one particular instance in this country an 80,000 kv-a generating station operated at an actual rate per kw.-hr., 20 per cent. lower than any previous performance on a commercial scale. A comparison of foreign with American practices show that the heat consumed per kw.-hr. for the most efficient French station was 22,240 B.t.u.; for the most efficient English station 20,150 B.t.u. and for the most efficient station in the United States, 18,030 B.t.u.

Generating Methods.—The tendency towards increasing the ratio of alternating current generation to direct-current generation is still evident. At the present time, of the total power generated in central stations, only 1.4 per cent. is direct. By way of comparison, 39 per cent. of the total power generated in central power stations in 1902 was direct. Of the total energy generated in the United States 80 per cent. is generated in fuel-electric plants and 20 per cent. in hydroelectric plants. The total developed water horse-power in this country is now 10,000,000, showing an increase of 950,000 horse power in 1925. It is estimated that there is about 22,000,000 additional water horse-power available for development. Throughout the world, according to the United States Geological Survey, 29,000,000 horse power was developed by water power in 1923. This represents an increase of about 25 per cent. in three years. The increase was about 1,500,000 in North America; 3,400,000 horse power in Europe, and 1,000,000 horse power in Asia. Probably one of the most important developments of the near future in steam generation, is the application of the mercury-vapor-steam cycle which has shown an economy better than 14,000 B.t.u. per kw.-hr. While an actual plant is using this cycle in operation, extensive applications have not yet been made. In general the cost of fuel has dropped somewhat in recent years due to increased efficiency; however, there has been an increase in fixed charges from 2.5 mils to 4.5 mils per kw.

MACHINERY

Tendencies in Design.—Some of the tendencies of modern design making for better efficiency and dependability are as follows:

a—The use of house turbines, auxiliary generators, and storage batteries for insuring the auxiliary power supply.
b—Isolated phase layout and the use of reactors and other protective devices in the switch house.
c—The duplication of auxiliaries, and the provision of excessive amounts of spare capacity in boilers and turbines.
d—The use of exceedingly high steam pressures, with a single stage of steam reheating during expansion.
e—The use of pulverized-fuel-burning equipment.
f—The use of variable-speed motors for driving auxiliaries.
g—The use of air heaters or economizers.
h—The use of large amounts of surface in the surface condensers for main turbines.
i—The use of the highest steam temperatures that are possible with existing materials.
j—The use of three- or four-stage bleeding for raising temperature of feed water to within 75 degrees of saturated steam temperature.
k—The use of large mills for pulverizing coal.

Experience has also shown that as the ratio of the number of stages of a turbine operating in the superheating region to the number operating in the moisture region is increased, the actual thermal efficiency is improved at a rate far in excess of the theoretical value. Tests recently made show that the heat input of a turbine installation may be decreased from 6 to 7 per cent. by resuper-heating the steam between stages. In hydroelectric design there is a tendency towards the use of larger water wheel turbines and generators. The object is not so much higher efficiency as lower cost per unit of installed capacity and decreased space. It is interesting to note that hydroelectric generators are becoming standardized. An excellent illustration of this is to be found in the fact that although the three 32,500 kv-a generators of the Niagara Falls Power Company were built by three different manufacturing companies, they are very similar in type and detail. The present range of speed in such generators is from 60 to 600 r.p.m. The chief improvement in generator design is increased accessibility. Completely enclosed units are being built to secure better control of the ventilation of the generator and the heating and ventilation of the generator station.

Hydroelectric System.—Of the recent developments in hydroelectric systems, that of the Pacific Gas and Electric Company is particularly interesting for two reasons, first because of the large number of diverse plants, and second, because it is the only system employing 220,000 volts at 60 cycles. The entire system comprises 28 plants with a total installed kv-a of 398,975, with transmission voltages ranging up to 220,000 and station ratings up to 81,000 kv-a per station. Both turbine and impulse wheels are employed, and the static heads range from 55 to 1,865 ft. Synchronous condensers are used at important stations to control the power factor and the voltage at the receiving end of long transmissions. This group of stations operates in connection with four steam-electric stations with a total installed capacity of 142,000 kv-a. These stations act as standbys and assist the hydroelectric plants in carrying peak loads. The largest water-wheel generators ever installed are the 65,000 kv-a units recently put in operation at Niagara Falls.

Central Station Practice.—An example of modern central station practices is found in the Philo Station of the Ohio Power Company which has two 40,000 kw. single cylinder turbines operating at a throttle pressure of 550 lbs. per square inch gauge, at a temperature of 725 degrees F. The water rate corresponding to a load of 40,000 kw. is reported to be approximately 8 lbs. per kw.-hr. The heat consumption for this station has been as low as 13,715 B.t.u. per kw.-hr. of net station send-out, corresponding to a load factor of 81 per cent.

This year in the new Richmond Station of the Philadelphia Electric, there will be two new 50,000 kw., 62,500 kv-a, 60 cycle, 1800 r.p.m. tandem compound turbo-generators. The New York Edison Company has just recently ordered two 60,000 kw., 60,000 kv-a, 1,500 r. p.m. single cylinder turbo-generators. The generator which supplies the power for the essential auxiliaries is directly coupled with the main generator and is driven by the main turbine. In the Trenton Channel Station of the Detroit Edison Company, power for auxiliaries is obtained from separate turbo-generators which operate as condensing machines and constitute a separate power plant within the large power plant. Five 30,000 kw. and nine 20,000 kw. turbines of the new Westinghouse multi-exhaust Bauman type have been placed in service. In the Crawford Avenue Station, Chicago, and the Richmond Station, Philadelphia, the power for the essential auxiliaries is to be obtained from a transformer, which is connected directly to the leads of the main generator.

Largest Turbine Casting.—It is interesting to mention the production of a turbine casting which is the largest ever made. The casting is for a 60,000 kw. steam turbine for the New York Edison Illuminating Company. It weighs nearly 45 tons and is over 25 ft. in length and 11 ft. high. Experiments are being carried on at the present time with extremely high steam pressures for turbine operation. One large company has employed pressures as high as 1,200 lbs. per square inch and reports successful operation.

ACCESSORIES

Electric Shovels.—These are being used more and more for handling coal and promise to replace the steam shovel in general application. One such shovel installed in the Brooklyn Edison Company's Hudson Avenue Station picks up 2½ tons of coal at one scoop, lifts it 100 ft., trolleys it in and discharges it into the hopper. The initial tests showed that the shovel is easily able to unload 200 tons per hour. Shovels are also being used for other purposes such as handling ore in mining. One company previously operated steam shovels handling approximately 3,000 tons of ore a day, and using five tons of coal at a cost of $10 per ton at the shovel. Electric shovels were installed which operated at a power consumption of 600 kw.-hrs. per day. This power costs the customer one cent per kw.-hr, making a total cost of $6 per day per shovel as against a cost of $50 for the steam shovel.

Switchboards.—There has been a radical change in the design of switchboards, particularly for use in industrial plants. The switchboards in vogue are known as the "Truck Type." One manufacturing company has placed more than 500 of these units in operation in the last year. Each unit is completely assembled at the factory and consists of a steel housing with a removable truck carrying all the apparatus upon which the continuity of the service depends. It has been found that this type of switching equipment has a number of advantages over the masonry or open-steel frame structure, some of which are the following: the equipment is completely assembled and tested in the factory; the apparatus is thoroughly interlocked so that mistakes in operation are prevented; live parts in the housing are completely enclosed, even with the truck withdrawn; the truck units are interchangeable and a spare can be placed in service quickly and safely even with a live bus; floor space and head room are saved. In connection with these and other types of switchboards it is important to mention the fact that various units such as switches, breakers, relays and meters are being made much more compact than previously. A decided improvement in reliability and accuracy of operation of such apparatus has been noticed in the past few years.

Substations.—Many engineers are now of the opinion that automatically controlled substations are less expensive than hand-operated stations in maintenance. The actual figures in one case cite a reduction from $43,000 to $10,000 per year for maintenance. The first automatic installation was made about ten years ago and one company alone has built nearly 2,500 such stations since that time. These stations render 2,200,000 kw. automatically serviceable and are divided as follows:

569—equipment for controlling 493,000 kw. in motor-generator sets, synchronous converters and condensers, ranging in size from a 25 kw. lighting motor-generator set to a 9375 kv-a hydroelectric unit; and

1890—feeder, supervisory, and power line switching equipments for directing the flow of 1,700,00 kw.

The early growth in the application of automatic operations was checked by war time activities, but since 1919 the business has greatly increased, the value for 1924 being about fifteen times that of 1919. It is predicted that before long we shall see very nearly all electric operations performed automatically and that workmen will be employed only to see that the equipment is kept in shape to function properly.

POWER DISTRIBUTION

Correctives. — There is at the present time a growing tendency of power companies to distribute alternating current at 4,000 to 5,000 volts rather than at 2,300 volts. This results in an increased demand for power-factor corrective apparatus to operate on the higher distribution voltages. The static condenser has already taken its place as a reliable and economical method for improving power factor, particularly for applications where static apparatus requiring little attention is desired. To meet this demand a new type of static condenser has been designed for direct connection on circuits, using as high as 5,000 volts. The condenser element is made up of alternate layers of laminated paper and tin foil conductor. The units are made in many sizes up to 300 kv-a.

Cables.—The use of underground cables for distribution is rapidly increasing. Their advantages for congested districts are obvious and with the growth of the larger and even medium-size cities are steadily overcoming the only real disadvantage, namely, a somewhat increased cost. Only a few years ago many engineers were convinced that underground distribution was commercially limited by the inherent characteristics of insulating materials, to not more than 25,000 volts. Recently an order was placed by The New York Edison Company for a number of miles of cable to operate at 132,000 volts.

One of the latest developments in alternating-current distribution is the interlacing or interconnected automatic network system. A group of high-voltage feeders supply distribution transformers which are interconnected on their low-tension sides to form a network. In such a system the failure of one feeder does not cause a failure of load supply, since the remaining feeder provides the necessary energy. The automatic network disconnects the distribution transformers from the network in case of a short circuit on a high voltage feeder, preventing feed back of energy from the network into the faulty feeder. It also recloses automatically when the normal voltage and phase conditions return.

LIGHTING

Output. — In the year 1924, the total value of lighting equipment in the United States was $205,886,000, an increase of nearly 14 per cent. as compared with 1923. It is estimated that 14,000,000 American homes are equipped with electric light. The house-lighting voltages throughout the country vary within a wide range, 115 volts promising to become standard for general lighting service.

In 1924, 1,750,000 carbon lamps were made. More than 261,000,000 large tungsten lamps were manufactured, or over 7 per cent. increase as compared with 1923. The average efficiency in lumens per watt was slightly higher. The 25-watt lamp is still the most popular size. The 40- and 50-watt lamps are next in demand. Twenty-three per cent. of all lamps are gas filled. Over 188,000,000 miniature lamps, including flash, automobile and Christmas-tree lamps were made in 1924, showing an increase of nearly 18 per cent. over 1923, 55 per cent. being used for automobile lamps. The average price of incandescent lamps was 30 cents and the total volume of lamp business in 1924 was $104,000,000. Incandescent lamps are also used for search lights with powers which go as high as 3 kw. A recent innovation is the incandescent lamp with an inside frost. This permits easier cleaning. Toggle and tumbler switches have come into much greater prominence for the control of house lighting units.

Illumination Intensity.—Enormous increases in intensity of illumination have been made. Where 4- or 5-foot candles were considered extravagant, this year finds 16-foot candles in the armature-winding room of an electric motor factory, 31-foot candles in a drafting room, and 14-foot candles in an adding-machine room.

Amongst the improved municipal lighting systems of the last few years, the alteration in Chicago's system is typical. The previous system in this city comprising many types of old-fashioned incandescent and arc lamps has been replaced by modern incandescent lamps ranging from 100 to 600 candle power. The addition to Chicago's lighting system cost $2,000,000 and involves 6,000 new units. In Detroit the new street-lighting system consists of nearly 18,000 units of high intensity, as compared with 650 old units. In connection with street lighting a new constant-current regulator has been developed with the unique characteristic of maintaining unity power factor at all values of the load.

There has been a great increase in the use of illumination for sign lighting. On January 1, 1925, there were 1,125,000 lamps in use for signs. Flood lighting is still increasing. Exteriors of many buildings are completely illuminated at night by flood light. A new application for incandescent lamps is to be found in manual and automatic traffic-control signals. Most of the large cities and many of the smaller cities have installed more or less complicated traffic signal systems.

An interesting application of electrical illumination is to be found in the airplane beacons which have been installed between New York and Chicago at an average distance of 15 miles apart. These beacons have proved themselves quite satisfactory for the guidance of the night air-mail pilots. The most powerful beacon in existence is on a mountain top at Dijon, France. It has a beam candle-power of one billion. It is used for the Paris-Marseilles flyers.

Incandescent lamps are being used extensively in place of open-flame lights in mines, giving added safety and dependability. Much experimenting has been done on incandescent bulbs for railway signals lamps. By means of narrow beams of light directed by very efficient optical systems, lamps as small as 0.4 of a candle-power are being used which give more than twenty times the illumination obtained from the old-style oil lamp used for this purpose. The arc lamp, which had such extensive use in the past, is now chiefly used for special lighting such as motion picture projection and the illumination for certain instruments requiring enormous intensities of light. Successful experiments are being conducted on tungsten-arc lamps, the present application being chiefly for the illumination for microscope slides.

The photo-electric cell now provides an accurate means for photometric measurements and is rapidly replacing the older methods. In connection with the manufacture of lamps and reflectors, it is of interest to mention that a new formaldehyde product, similar in many of its properties to glass, has been discovered. The new material can be turned on a lathe, can be rolled, folded and takes a high polish. It is not brittle, and it absorbs ulti-violet radiation.

TRACTION AND DRIVE

Electric Railways.—Electrification has been steadily increasing. A survey made in 1924 showed that throughout the entire world there were 2,351 electric locomotives with an aggregate horse power of 4,259,148. Of these, 1,446 locomotives, totalling 2,780,692 horse power operated on alternating current, while the remaining 905, totalling 1,478,456 horse power, operated on direct current. The distribution amongst the five leading electric railway countries was as follows:

Country	*Number of Electric Locomotives*	*Total Horse Power*
Italy	504	1,209,736
United States..	465	862,956
France	366	384,460
Germany	304	518,841
Switzerland ..	214	384,152

One of the most interesting developments in electric railways is the combination of single-phase alternating-current supply to the locomotive with the direct-current drive. A recent test of this equipment on the New York, New Haven and Hartford lines used 11,000 volts alternating current between track and trolley and inside of the locomotive there was a transformer which stepped down this voltage. This lower voltage operated a synchronous-motor direct-current-generator set, which in turn supplied the direct-current motors on the trucks. Due to the high efficiency of the various units employed and their compactness, it has been proved possible to obtain the advantages both of alternating-current supply and direct-current motor operation.

A motor-generator type of locomotive has recently been built for the Detroit and Ironton Railway. One of the unusual features in connection with the branch for which this has been built is the use of 22,000 volts between track and trolley. The locomotive contains its own substation which includes a transformer and synchronous-motor-generator set. The locomotive transformer is 2,000 kv-a and may be connected to receive 22,000 or 11,000 volts and will deliver secondary current at 1,250 volts. The traction motors are 225 horse power, 600 volts, direct-current series machines.

Several of the American railways have recently adopted gas-electric cars for branch lines. An example of this is the Trenton Branch of the Reading Company. This branch is nearly four miles long and has four intermediate station stops. The maximum grade is 1.1 per cent. The service was previously handled by two steam locomotives, each weighing 211,625 lbs. The present gas-electric car weighs 90,000 lbs. The gas engine delivers 250 horse power at 1,100 r.p.m., has six cylinders and is water cooled. The main generator is 600 volts. Two 140 horse-power motors are located on the forward truck of the car. The operation is very simple and speeds up to 46 miles per hour are obtainable.

An interesting development is the application of the Diesel electric locomotive for yard switching. Its particular advantage is to be found in the fact that it does not incur the heavy standby losses found in the steam locomotive.

Marine.—Electric drive is being used more and more extensively for ship propulsion, and turbine electric drives are to be found on naval craft and ferry boats in increasing numbers. The most interesting development, however, is the use of Diesel electric drives which have recently been applied to electric hopper dredges, tankers, tug boats and fire boats.

TELEPHONE ENGINEERING

Telephone.—One of the most interesting advances in telephone practice in the past few years has been the growth of automatic switching systems. The traffic in many of the large cities has increased to such an enorous extent that the telephone companies have felt that the only possible way of giving adequate service was by replacing the manual system by the full automatic system. In January, 1925, there were 993,000 machine switching telephone stations in operation in the Bell system, as against 576,800 in January, 1924. In January, 1925, there were 185,300 machine stations in New York City, operating out of 21 central offices.

Due to the very complexity of the telephone system in a large city such as New York and the huge investment required in apparatus, it is necessary to replace the existing manual exchanges very slowly. This condition has forced the telephone companies to develop automatic apparatus in such a manner that it can be made to function in connection with manual apparatus. Therefore in those cities in which these changes are being made, part of the traffic originates from a manual exchange and terminates in a manual exchange; part originates in a manual exchange and terminates in an automatic exchange, and vice versa; and some both originates and terminates in automatic exchanges. The introduction of full automatic switching has made many problems for the telephone companies since it is not only necessary to install the new apparatus, but also to educate the telephone public in its proper use in order to insure continuity of good service when a given section is cut over from manual to automatic switching. There is little doubt that most of the larger cities will have full automatic telephone service within the next ten or fifteen years.

New York—Chicago Cable.—The toll and long distance service of the various telephone companies has steadily improved in scope and quality of service. In August of this year a very important telephone cable connecting New York and Chicago was completed after seven years' work. This cable is 861 miles long, 717 miles of which are overhead and the remainder underground. Between the two ends are seventeen repeater stations, and the cable is loaded every 6,000 ft. The cable provides 250 telephone channels and 500 telegraph channels. The total cost was approximately $25,000,000. It is the longest cable of its kind in the world, the next longest being the Boston to Washington cable which is 450 miles in length.

The multiplexing of both telephone and telegraph wires by the use of carrier currents, which was made possible by the simultaneous advent of the thermionic telephone repeater and the electric wave filter, is reaching important proportions. In the case of telephone circuits, it is usually customary to add either three or four high-frequency channels in addition to the voice-frequency channel to a pair of wires, thus increasing the capacity of the physical circuit either four or five fold.

The shortest length of line which it is now economical to multiplex with carrier facilities lies between 150 and 200 miles, but it is expected that further improvements and simplifications will extend the field of applicability of carrier systems. At the present time there are about 45,000 miles of carrier telephone channels and 180,000 miles of carrier telegraph channels in commercial operation in the United States.

Havana—Key West Cable. — The longest undersea telephone cables in the world connect Havana with Key West, the distance being about 110 miles. These three cables provide grounded telegraph circuits in addition to the voice-frequency telegraph circuits and also, above the range of frequencies assigned to the telephone channels, supply carrier telegraph facilities. Among the developments which have made these cables possible are refinements in cable transmission theory. On the basis of this theory the cables, which are the continuously loaded, single-core type, were designed with a cylindrically wound copper tape, concentric with the central conductor but insulated from it, this tape together with the armor wires and sea-water forming a return path of lower impedence for the high-frequency currents than the armoring and water alone.

The problem of inductive interference is being systematically investigated by a joint committee of the National Electric Light Association, The Western Union Telegraph Company, The Postal Telegraph and Cable Company, The American Telephone and Telegraph Company, The American Railway Association, The American Electric Railway Association, and representatives of the electrical manufacturers. The main matters under consideration are the measurement and effect of residual voltages and currents, the wave form of generators, and the relation between the telephone interference factor and noise, the harmonics due to the permeability of the steel in transformers and other apparatus.

TELEGRAPH ENGINEERING

Telegraph.—Two new systems of carrier current telegraphy for use on telephone lines have been placed in service this year. The first employs carrier-frequencies below the voice range and can be used simultaneously with telephone messages. The second system uses frequencies in the voice range, 400 to 2,000 cycles; affording 10 simultaneous two-way channels over a single pair of telephone wires. This system is used only when the pair of wires is not being used for telephone communication. Both new systems depend upon ultra-sensitive relays which have recently been developed.

New York—Azores Cable.—A remarkable cable has just recently been completed between New York and the Azores. This cable is of special interest because of its ability to handle four times the traffic of previous cables of the same size and length. This is due to the use of the new magnetic alloy known as permalloy. This magnetic alloy under the conditions used has a permeability of 2,300 as against 115 for the material used in previous cables such as the Key West-Havana cable. The New York-Azores cable is helically wound with permalloy tape. In addition to its high permeability this type has low hysteresis and eddy-current losses. The cable can transmit 2,000 letters per minute. Another permalloy cable, connecting New York and Penzance, England, has been proposed, and will probably be laid in the near future.

A great increase in telegraph speed has been made possible through the development of a machine called the "Stop-Start" telegraph printer equipped with a typewriter keyboard requiring only momentary synchronism. It can transmit from forty to eighty words a minute, any distance up to 5,000 miles. Printing-telegraph service has been successfully established between New York and London, over a 3,900 mile cable with six regenerative automatic repeater stations. Tape printers are used.

RADIO ENGINEERING

Radio Telegraph.—Very successful applications of radio telegraphy have been made in the air service. Light and compact transmitting and receiving sets are carried by many of the military aircraft. Another important application is the direction finder which permits the exact location of ships, even in dense fog.

Much experimentation has been done during the last year in connection with short waves, and communication has been established utilizing waves from 100 meters to less than 5 meters. One particular type of short-wave circuit is now in operation between New York and Europe, New York and South America, and between San Francisco and Hawaii. The adoption of short waves for communication over long distances is contrary to the indications of earlier experience, in which it was found that the longer the distance the longer should be the wave-length for reliable service. In employing short waves for long distance communications, these waves are launched into space like high-angle gun fire in such a manner that the waves travel in the upper atmosphere and come back to earth some distance away.

The adoption of short waves has enormously increased the number of possible non-interfering communication channels. Almost all of the trans-oceanic telegraph stations in the world are crowded into a wave-length band 10,000 cycles wide but the short wave band below 100 meters includes 10,000,000 cycles; thus there is room for a thousand times as many messages as are now being handled by all the long wave stations put together.

In the commercial radio systems the adoption of what is known as the Beverage-Rice antennæ system eliminates practically all static and intercepts on one antenna all the signals from the stations in Europe. These signals are then automatically separated in more than a dozen receiving sets and sent over line wires to the operating room in New York City. The antennæ system consists of two separate antennæ, each ten miles long joined by a transmission line.

Radio Broadcasting.—In the past year the most outstanding novelties in the operation of broadcasting stations are to be found in the use of higher powers, up to 50 kw., the interconnection of stations both by short waves and land wires, and the marked increase in the faithfulness of tone modulation and amplification. The attitude of broadcast listeners has totally changed since the inception of broadcasting, with the result, that the industry has closely followed the public's desire. In the early days the novelty of radio telephony was so great that the character and technical quality of the broadcasted material was completely overlooked. It seems that the broadcast listener was interested only in determining how far he was able to receive and also how many stations it was possible for him to enter upon his log sheet.

While great improvements have been made in the commercial receiving sets, much is still left to be desired from the standpoint of tonal quality. Some of the most recent improvements involve the simplification of control (many sets now can be operated with one dial for station selection), reliability of operation, ease of maintenance (house-current power-supply), and a general improvement of quality, particularly due to the introduction of better audio-frequency amplifiers and loud-speaking apparatus, for example, the cone type of loud speaker.

Some of the probable advances lie in the direction of more economical vacuum tubes, a more efficient loud-speaking apparatus which does not require the use of power vacuum tubes for its successful operation and a general simplification and standardization of design. The present tendency amongst broadcasting stations is towards interconnection. In the case of important events, such as President Coolidge's address of November 3, more than twenty-five stations spread throughout the country have been interlinked, permitting the reception of the message at virtually every place in the United States.

Radio Telephony.—The development of radio telephony for commercial messages is making notable progress. An experimental system has been demonstrated by telephone engineers which enables a passenger on a ship, several hundred miles at sea, to communicate with any telephone subscriber on the land using the latter's regular telephone instrument. The system is duplex in its operation, permitting the subscriber on land and the person at sea to hold a two-way conversation exactly as over the usual telephone circuit. Although most of the development work was done during the years just previous to those here reviewed, there has been no very extensive installation of ship-to-shore telephony, largely because of the numerous commercial problems involved.

The serious study of transatlantic radio telephony continues. To illustrate the progress which has already been made: in a recent demonstration, a speaker in New York talked through his ordinary telephone to a group of persons in London, the voice being carried from New York to the radio transmitter located about 70 miles out on Long Island, where it was automatically relayed to the transatlantic radio link. The extremely difficult character of the problems involved in the offering of regular commercial service may be gathered from the fact that, due to the erratic variations of atmospheric conditions as they affect the transmission of radio signals, the sending power required to produce a given intensity of received signal may increase by a factor of 10,000 within the space of a few hours.

Miscellaneous.—During the past year photographs were successfully transmitted across the Atlantic by radio, and reproductions appeared in many of the American newspapers. In April, 1925, the first commercial picture-transmission service was introduced. It embraces the cities of New York, Chicago and San Francisco, making use of the long distance telephone and telegraph lines between these points. The actual sending time of a 5″ x 7″ picture is only seven minutes. The picture to be sent is prepared in the form of an ordinary transparency and after transmission it appears as a negative from which prints can be made without delay.

PHOTOGRAPHIC ENGINEERING

Photographs by Wire.—During the convention of the American Medical Association in May, electrocardiograms were transmitted by a phototelegraph method from a hospital in a middle western city to the medical convention in Atlantic City. At the same time the heart sounds of the patient in this same clinic were transmitted over telephone wires, amplified and faithfully reproduced in the stethoscopes of the physicians attending the convention. In this manner an actual diagnostic conference was held by these physicians in Atlantic City although the patient was many hundreds of miles away.

Another recent interesting application of the transmission of photographs by wire has been made in several municipal police departments. They transmit from one city to another, both the photograph and the fingerprints of fugitives. Another very important addition to the art of communication is the perfection of the apparatus which is known as the public address system. This apparatus is used in two forms: local and remote. In the local form, the voice of the speaker is collected by a microphone, greatly amplified and reproduced by a group of powerful loud speakers located above the speaker's head. In this way a speaker using his natural voice intensity can readily be heard by an audience filling a large auditorium or stadium. In the remote type, the speaker has placed by his side a microphone and the amplified output of this microphone is connected by telephone wires to one or more auditoriums in which are located the necessary re-amplifying and loud speaking apparatus. In this manner the speaker, or any other source of sound, may be heard simultaneously in several auditoriums, located, if desired, in different cities.

MOTOR ENGINEERING

Applications. — Since the starting and running requirements of motors are very different, and a large part of the development of induction motors has been in connection with running conditions, it is interesting to note that recent investigations have shown how to improve the starting characteristics of these motors. It is now possible to build induction motors in which the starting current is limited to approximately 4½ times the full-load current.

During the last year a new type of synchronous motor having field poles of special design and with rotor windings arranged for two methods of connection was developed. The particular feature of this new motor is that it has two running speeds. This promises a great extension of the application of the synchronous motor for such uses as mine fans, and ammonia compressors in which it is distinctly desirable to have two efficient running speeds. The cost of this motor is only slightly higher than that of an ordinary motor whose horse power and speed are equal to the low speed rating of the two-speed motor.

Another very important motor development is the new adjustable speed brush shifting alternating current motor. It is intended for single and polyphase, 60-cycle circuits operating at 220, 440 or 550 volts and has a three-to-one speed range which is controlled by shifting the brushes. The high-speed power factor is about 95 per cent. and the low-speed power factor about 70 per cent. The efficiency, which remains nearly constant over the entire speed range, is high as compared with the wound rotor induction motor employing secondary resistance. Among the applications of this new motor are: cloth-pressing machines, rubber calenders, oil-refinery cross-process pumps, rolling mills, machine tools, newspaper presses and dough mixers.

New types of alternating current motors have been designed for the operation of elevators, which overcome most of the previous disadvantages of the ordinary alternating current motors when used for this purpose. These new motors include single- and double-winding induction motors, double motor sets, single and polyphase commutator motors.

A new high-frequency alternator is now available for supplying high-frequency for inductive furnaces. These furnaces are being used largely for producing alloys of nickel-iron, gold-platinum, osmium-iridium, and other high melting-point alloys where freedom from contamination and thorough mixing are necessary.

Many motors are now built totally enclosed. The ventilation is obtained from an external source through pipes. These motors find application in places where fumes and acids would cause serious damage to the motor.

A special type of generator has recently been designed with a drooping voltage-current characteristic for use is arc-welding outputs. This drooping characteristic is necessary for the lowered resistance of the welding circuit after the arc current has been established. To avoid the cost and complication of separate excitation, the generator has a split field. By using the armature-reaction on this field, and installing a third brush, a constant voltage is obtained. This generator is being supplied as an integral part of a compact portable arc-welding set.

RECENT APPLICATIONS

A marked increase in the application of electricity for industrial heating has taken place recently. The present methods of heating by electricity are the metallic resistor, electric arc, and magnetic induction. The metallic resistors have been fairly well standardized by the manufacturers, and range in size from 50 watts to cast-iron protected units of several kilowatts. In general the temperatures obtainable by means of such resistors do not exceed 500 degrees F, unless they are used in specially constructed ovens or furnaces, under which conditions it is possible to obtain temperatures as high as 2,000 degrees F.

One automobile manufacturer alone has 14,000 kw. of electric japan baking ovens, and factory after factory is replacing its oil and gas and steam ovens by electric ovens. Among the chief advantages are uniform temperature, automatic temperature control, lower maintenance, reduced personal hazard and the elimination of noise, dirt and fumes.

With the improvement of the radio, the attention of the public was brought to the comparatively poor quality of the talking machine. Research in this field has been stimulated to such an extent that at least two large talking-machine companies have produced machines which operate electrically; that is, the conversion taking place between the record and the listener is principally electrical rather than mechanical. This has resulted in a material improvement in the quality of reproduction. Moreover, at least one large company is now manufacturing its master records by an electrical process, which has greatly increased the tone range and volume obtainable from the record.

A new X-ray tube has been designed having a 50-milliampere output at 250,000 volts, which is being used in research, manufacturing processes and therapeutics. This tube is the largest yet made, commercially, and has a water-cooling system, whereby circulating water is carried directly to the inside surface of the anode of the tube.

A new type of self-contained portable X-ray outfit has been developed for use in dentistry, medical diagnosis, physical laboratories, and other applications. The tube and transformer are completely immersed in oil. The apparatus is quite safe and is easily operated and can be connected directly to the 110-volt alternating-current house-current supply.

An interesting application of high-frequency electricity is to be found in the so-called Radio Knife. The radio knife to a certain extent can take the place of the scalpel in surgery. This knife, which consists primarily of a round ended stylus, and a metal plate which is placed under the body of the patient, has impressed between these two electrodes a high frequency (one million cycles) source of electricity. When the stylus is brought in contact with the skin of the patient a cut is made electrically into the patient, the depth of this cut being regulated by the intensity of the current and the angle of the cut by the angle at which the stylus is held. The incision has the advantage of being self-cauterizing and almost bloodless. Surgeons who have used this device state that it has future possibilities in surgery.

A very important instrument recently developed is called the "Stethophone." This consists of a microphone of special construction which is placed over the heart of a patient. The microphone feeds a vacuum-tube amplifier which is also equipped with filters which operate a series of telephone receivers over which are placed the bells of stethoscopes of medical students or of physicians who wish, simultaneously, to listen to the heart beats of the patient under examination. In this way a large audience of such students and physicians are enabled to study the heart sounds of the patient together with the lecturer. By means of the filter circuits it is possible to subordinate any of the main heart sounds, thereby making sounds such as murmurs more audible, and consequently more easily studied.

Among many new important instruments designed for electrical laboratories is a six-element portable oscillograph. This instrument is particularly valuable because of its completeness, its ease of operation and its ability to record six variables simultaneously. It is being used successfully for tests in automatic substations, electric railway locomotives, power plants, circuit breakers, relay and circuit tests. An important addition to testing instruments is the Klydonograph, or surge recorder. By a photographic method this instrument records graphically the nature, time, intensity and duration of line surges.

RESEARCH

Important recent researches in electrical engineering have concerned themselves with the properties of dielectrics, solid, liquid, and gaseous. Due to the increased use of very high voltages both on open-wire and cable construction, it is extremely important to note the effects of these voltages upon the properties of such dielectrics as are commercially available. Many of the large companies and some of the technical schools have installed high-voltage generating apparatus with which to investigate dielectric properties.

A detailed study of the magnetic properties of various magnetic materials has occupied the research laboratories of the large manufacturing companies to a very large extent during the last year, chiefly in an endeavor to permit the calculation of the magnetic properties of the materials used in machines, rather than to depend upon empiric formulas for design.

A study of the molecular and crystal nature of solids has been greatly advanced in the past year by the use of the X-ray refraction apparatus. So important is this form of investigation that one manufacturing company is building X-ray apparatus of this nature on a commercial basis. It is believed that much of the empiric knowledge concerning the properties of various compositions, such as the alloys, will be placed on a firm theoretic base by the use of this X-ray analyzer.

Extensive investigations have been made on the properties of cold light. While most interesting material of a theoretical nature has been gathered on the properties of luminous and phosphorescent substances, both animate and inanimate, there is at the present time no very extensive application which can be made of these properties.

The vacuum tube rectifier circuit has been altered in the past year in such a fashion as to permit the production of alternating currents from a direct current source. The inventor of this scheme has termed the apparatus the "Inverter." Although only laboratory models have been built thus far, it is quite likely that the development will permit the use of this apparatus in power sizes, thereby giving a static device for the transformation of direct current energy into alternating current energy.

Experiments have recently been conducted in France with a three electrode tube containing mercury-vapor. By proper adjustments of the constants of the circuit in which this tube is used, it has been found possible to obtain amplifications of more than 1,000,000 to 1. If this apparatus becomes commercially available it will have numerous applications.

An American laboratory has succeeded in producing bars of copper, each bar a single crystal, with the result of increasing the electrical conductivity 13 per cent. above that of commercial copper used for electrical conductors.

The sustained oscillations of certain crystals exhibiting the Piezo-electric effect have been used as frequency standards in communication investigations. The constancy and accuracy obtainable is so great that certain radio transmitters are using such crystals for master oscillators.

Among the new magnetic materials developed for telephone purposes, one consists of very finely divided iron dust cemented together under extremely high pressure to yield a material of substantially the same density as iron, of only 1/20,000 the electrical conductivity of iron, nearly the same initial permeability as iron, and yet, because of its finely divided ingredients and the consequent microscopic free poles distributed throughout it, possessing practically no residual magnetism even after exposure to strong fields.

MECHANICAL ENGINEERING

By Calvin W. Rice

Secretary, American Society of Mechanical Engineering

and

Leon Cammen

Associate Editor, Mechanical Engineering

INTRODUCTION

Engineering Morale.—One of the most significant things, considering the field of mechanical engineering as a whole, is the fact that the engineer is gradually reaching, and in some lines has reached, the point where he is not afraid to undertake anything, from a point of view of engineering. In the past when a question of unusual performance of a machine came up there frequently was apprehension as to how this machine would work. This applied to structures of unusually great size or machines subject to unusually big stresses or running at theretofore unknown speeds. In fact, when the Quebec Bridge collapsed twice, the most prominent engineers of the country agreed that the failures were due simply to the then prevailing lack of knowledge of the behavior of materials under the stresses to which they were exposed in that particular structure. When the question of forty or fifty thousand k.w. generators first came up some ten years ago the designers were frankly uncertain as to the reliability of machines of such size.

All this was due to lack of exact knowledge of the underlying processes of operation of machinery and behavior of materials. What was then called factor of safety was (and was frankly recognized to be), to a considerable extent, of the nature of a factor of ignorance. The work of scientists and engineers within the last decade in particular has eliminated a good deal of the uncertainty which prevailed in this respect. New methods have been developed which make it possible for the engineer to stop guessing and supposing as to what is going on and to know instead exactly what he has to face and to what extent the materials and machinery which he produces are capable of handling any situation that may arise.

It is because of this that the engineer is no more afraid to go the limit in his designs. In 1916 the Ford Motor Company designed a plant carrying a superheat up to three hundred and fifty degrees while pressures in steam boilers up to 600 pounds were earnestly advocated. The reservation was made, however, that there was still a problem how to obviate the mechanical defects involved in the design of engines and turbines for such steam pressures. Today boilers are being built in this country for pressures up to 1,200 pounds and there is no serious question in anybody's mind as to their ability to work in a satisfactory manner. This is so because we know today how the materials used in the boilers will behave at temperatures in excess of 1,000 degrees Fahrenheit. There is no longer any reason to fear hidden defects due to improper casting such as blow holes or slag enclosures because the use of X-ray permits to see what is inside the casting and at the boiler wall.

Growth of Exact Knowledge.—With the knowledge thus obtained (and we are only at the beginning of engineering work backed by ample exact knowledge) the engineer is reaching out beyond the most optimistic imaginings of only ten years ago. Locomotives with engines operating at 350 pounds pressure; steam turbines of 80,000 horse power, of which a single one would be sufficient to supply all the electric power needed in some of the smaller European countries; measuring methods permitting an accuracy of the order of 1/200,000,000 part of an inch; machinery actually running at speeds of 660,000 revolutions per minute; photographic methods that permit to record easily the flight of a bullet; observation methods that show the motion of a wing of a dragon fly; these are but a few of the very many significant achievements of modern mechanical engineering.

Natural Resources.—It is also very significant that within the last few years and in the past year particularly, as far as one can judge from public expressions of engineers, the feeling of fear as to the continuation of natural resources is disappearing. When a century ago Malthus propounded his famous theory in accordance with which the growth of food resources occurred in arithmetical progression and the growth of population in a geometric progression with the threatening result of population outrunning food supplies, there was real perturbation among scientific men. Some twenty years ago Crookes startled the world by predicting that the exhaustion of the supply of nitrate fertilizers would lead the soil to lose so much of its productivity as again to threaten the existence of the human race. And it was only a few years ago that the late Senator La Follette expressed the opinion in a debate on the floor of the Senate that "dollar a gallon gasoline" was in sight within a few years, while predictions as to the exhaustion of coal and consequent stoppage of the wheels of industry have been in the past too numerous to mention.

Production of Power.—Engineers have given up making such predictions nowadays. In the first place they found that with the increase in the perfection of design of our machinery such economies have been obtained as to decrease the use of natural sources of power while increasing the production of power. In the second place they have solved so many difficult problems in the past when it became really necessary to have them solved as to acquire a serene confidence in their ability to handle any situation that may arise. The threat of exhaustion of oil as a source of gasoline was met by better design of the engines which is already saving about twenty-five per cent. of the fuel used, and by processes of cracking which increased the recovery of gasoline from oil from twenty to about fifty per cent. And then the engineers are confident that by the time the oil supplies are exhausted they will either design engines that will use an entirely different fuel or produce engine fuel oils from different sources, be it by converting lime and coal into calcium carbide, carbide into acetylene and acetylene into alcohol, or perhaps by converting coal direct into motor oil, or by burning coal to carbon monoxide and synthesizing a fuel by catalysis, or other means.

It is well, however, while recognizing the enormous influence of the research on development of modern engineering not to overestimate it. An important investigation was completed last year in Germany on the laws of radiation of heat in furnaces. It was realized that phenomena of heat radiation exercised a profound influence on the performance and efficiency of furnaces and it was expected that a more thorough knowledge of these phenomena would help in the design of furnaces. It was rather surprising to find that the main fact that this extensive investigation has established was that the furnaces now in existence have been correctly designed and were in accordance with laws unknown at the time when they were built. Apparently by some mysterious faculty of reasoning engineers have found the correct solution of the problem even though they did not know enough about it at the time to prove that it was the correct solution.

MACHINE TOOLS

Progress in Construction.—There are seldom any spectacular developments in this field. There were not any in the past year, which does not mean, however, that substantial progress has not been made. This progress was partly in the construction of bigger and heavier tools. Thus, a huge turning machine was recently built which swings 300,000 pounds between centers and has eight electric motors. A 36-inch grinding machine was built on a carriage for use anywhere along its 45 feet of working length. Then an enormous machine was built for planing and upsetting steel plate designed for making lock-bar pipe. This machine has two main bodies, 45 feet in length, carrying lead screws. The screws alone are six inches in diameter, have triple threads and are connected to a drive shaft operated by a two hundred horse-power motor. The machine has to be immensely rugged, as in one operation, upsetting the edges of one-half inch plate, the pressure of approximately 400,000 pounds is applied.

On another hand, it will be found that precision machinery has also developed greatly. Only a few years ago working to 1/1,000 of an inch was considered high accuracy. Today sensitive comparators and light interferometers provide a precision of the order of 1/1,000,000 of an inch for gauges and indirectly make a real interchangeable manufacture possible at a low cost. Not only that, but entirely new instruments are being developed all the time. There was known for a long time an instrument called stroboscope, which permitted to measure the speed of rotation of parts without touching them. This has been now developed into a rotoscope, which enables to observe, as if they were standing still, rotating bodies, having speeds ranging as high as 20,000 revolutions per minute and possibly higher. Such instruments are applied, for example, for studying vibration of high-speed shafts or determining causes of disparity in the output of sewing machines, all supposed to be driven in the same way and at the same speed. The motion of a dragon fly's wing has also been investigated, by the same apparatus, and it has been found that the wings, contrary to hitherto made assumptions, are not flapping up and down but are caused to execute a definite conical movement. Twenty or ten years ago all of these matters were subject to guess work. Now they are gradually coming into the fertile field of exact knowledge.

Velocity of Machinery.—It is primarily because of the application of such knowledge and the ability to produce parts of high precision that the velocity of machinery used in modern engineering is rapidly increasing. Only a few years ago 1,600 revolutions for an automobile or aëroplane engine was considered to be about the limit of commercial speeds and an attempt by an American automobile builder to put on the market a 3,400 r.p.m. motor failed rather dismally. Today the light aëroplane engines run at speeds up to 4,000 revolutions without any distress, while, in special machinery, speeds are beginning to be employed which are scarcely believable even in these days of ever rising achievement. Thus, in France a device called the superhigh speed turbine has been built which attained a measurable speed as high as 4,000 revolutions per second. There is reason to believe that the actual maximum speed was in excess of 11,000 revolutions per second, equivalent to 660,000 revolutions per minute. Rotors of special steel are now under construction which it is expected will permit the device to run at velocities of 1,000,000 revolutions per minute.

POWER GENERATION

Utilizing Tides.—Apart from such conventional methods of power generation as the utilization of rivers and waterfalls, and oil, gas and steam power (discussed elsewhere), an increasing amount of attention is being given to other forms. Utilization of the power of the tides has for scores of years attracted the attention of inventors, but until quite recently all attempts at doing it in a practical manner have failed. In the last year for the first time a true ray of hope became visible. In France some successful experiments were made with the Pinard-Sala system in which a funnel is used located under water with the wide end open towards the incoming waves. The funnel then contracts gradually and ends in a vertical cylinder in which operates a floating piston. The power delivered to the piston is determined therefore not by the ratio of the crest of the wave to its trough but by the total mass forced into the funnel which is proportional to the ratio between the cross section of the funnel and that of the vertical cylinder. This embodies therefore fundamentally a principle somewhat similar to that successfully used in the hydraulic press. In tests made with the conduit of sheet metal, twenty-three feet long, it has been found that with waves which are not of sufficient violence to knock over a man so much pressure was obtained in the conduit itself that the blades of the latter were twisted in a few moments and the conduit burst.

Another development in the direction of utilizing the force of the tides which deserves earnest consideration is embodied in the scheme of Dexter S. Cooper for harnessing the rise and fall in the Bay of Fundy. There it is intended to enclose the Passamoquoddy Bay by two walls admitting water through a series of gates into the Bay on the high tide and permitting this water to run out at the other end through another series of gates at low tide, thus obtaining a continual and steady supply of power. By a referendum vote the State of Maine approved granting permission to Mr. Cooper to install his project. Further approval of the project would, however, be necessary by the Federal government of the United States and the Dominion of Canada before actual work is started.

Harnessing the Winds.—In another direction an earnest effort is being made to put the wind to work. The windmill and the sail are among the earliest forms of generation of artificial power, but they lost their importance in industrial countries and on the high seas with the development of steam power. They are apparently coming back, however, particularly in Europe where in the last year several new types of windmills embodying the most recent advances in engineering design have been built. In this the designers of windmills have been particularly assisted by information gathered in aëro-dynamic laboratories in connection with work on aëroplanes.

Another line of development deals with the application to power generation of the so-called Magnus effect. Magnus, a scientist of the middle of the Nineteenth Century, noticed that if the wind blew against a stationary cylinder the pressure was the same on both sides of the cylinder, but that if the wind blew against a rotating cylinder the pressure on one side was greater than on the other and the cylinder tended to move across the direction of the wind. He used this observation to explain the deviation on projectiles discharged by rifles and guns. The German engineer Flettner applied this principle to ship propulsion. On the small vessel Buckau he erected a cylinder about 61 feet long and 9.2 feet in diameter and rigged up a small electric motor by means of which this cylinder could be rotated. It was found that even moderate winds developed sufficient force to give the ship a speed favorably comparing with that which it would have under conventional sail rigging. A Swedish engineer, Savonius, improved this device by cutting the cylinder in half and putting it together in such a manner as to leave a short distance between the axles, thus producing an off-set effect. It is claimed that the Savonius cylinder, with the same wind and the same power consumption for rotating it, gives a greater output than the Flettner rotor.

Earth's Internal Heat.—Among other things the subject of utilization of the internal heat of the earth was given increased attention. The great success of the plant at Larderello, Italy, where the steam coming from underground sources in the form of soffioni is used to drive turbines, has attracted attention to the possibilities of the utilization of subterranean heat. A small power plant was installed in Sonoma County, California, and tests made in the latter part of the year have shown that it is fully capable of steady and economical operation. There is no likelihood that very large amounts of power can be produced this way, however, as only in comparatively few places are the conditions sufficiently favorable.

STEAM POWER ENGINEERING

Expansion of Turbine.—The progress in steam power engineering within the last years has been enormous. Where a few years ago there was a question as to whether 40,000 k.w. in a single unit was practical, today a steam turbine of 80,000 k.w. is under construction and units of 100,000 k.w. and more are in sight. It is difficult to realize what a steam turbine of 80,000 k.w. means. It is not a big piece of apparatus as far as size goes, and perhaps a better comprehension of its power may be had if it is considered that one such unit would probably be sufficient to supply all the electric light consumed today in a country like Jugoslavia with a population of fifteen million souls. In proportion to the increase of the steam turbine there was an increase in auxiliary equipment. Although the increase in consumption of the turbine and the bleeding of steam at successive stages for water heating have lessened the amount of steam to be condensed per k.w. capacity, the modern condenser has increased in size to 70,000 or 80,000 square feet of surface and requires such enormous quantities of water for condensing purposes that a plant of large capacity can not be located except within reach of a lake, river or ocean.

The efficiency of power generation has also increased enormously. Twenty pounds of steam per k.w.-hour was considered quite good only a few years ago. First class power plants are making a k.w.-hour on fifteen pounds of steam today and ten pounds is distinctly in sight. "A pound of coal per kilowatt-hour" is believed to be a goal within reach of the mechanical engineer.

Other types of steam generators are appearing. In this country a unit is being installed by the Edison Electric Illuminating Company of Boston in which are to be employed a boiler and turbine operating at 1,200 pounds pressure. So great are the stresses induced in such a structure that the boiler drum is made from a forging with walls four and one-half inches thick. All steel castings used in the work, in addition to ordinary testing, have been examined for flaws by X-rays, in addition to which special tests have been developed for the testing of piping, valves and fittings.

A still higher pressure, 100 atmospheres or 1,422 pounds rating is employed in an installation at the Vienna Locomotive Works (Vienna, Austria), where the steam is generated by the Loeffler system. In this method the water is not evaporated in water tubes but in the boiler drum lying outside of the furnace, for instance, near the turbine, so that the latter automatically regulates the evaporation. Evaporation is achieved only by admitting superheated steam to the evaporator and then an increase of pressure may be obtained by varying the heat content of the super-heated steam. It offers the greatest safety even at the maximum pressure as only the superheater consisting of coils of tubes of small diameter lies within range of the furnace.

Improving Furnaces.—The modern power plant engineer is all the time endeavoring to burn more and more fuel for the same furnace capacity, thus imposing on the furnace walls temperature loads of a magnitude unheard of previously. It has already reached the point where an ordinary furnace wall does not stand up any more and various ways are being devised to increase the capacity of the furnace wall to handle the present enormous duties.

One such way to improve the furnace was embodied a couple of years ago in the Hell Gate Station in New York City where water-cooled walls have been installed. Another way, however, is to improve the ability of the refractory substances used in the furnace walls to stand up under the present conditions of intensive firing. The problem is not an easy one because research in this direction has indicated that present refractories would have been fully capable of withstanding, under the temperatures developed in power plant furnaces, had it not been for the fact that coal contains materials which at the temperatures present in the furnace, unite with the refractories and act as fluxes, lowering the melting point of the refractories. To meet this condition it has been suggested to line the furnace walls where they come in contact with fuel with special refractories made from the fuel ash, the idea being that this lining would not be fluxed by coal constituents and would prevent their fluxing the furnace wall proper. Another direction in which great promise is seen is in the use of super-refractories, among which sillimanite may be mentioned. Sillimanite is a mineral which occurs in small quantities in the United States and is said to have been discovered in larger quantities in India and which can also be produced artificially. The study of refractory materials for furnace walls in America is considered so important that it has been taken over by the American Society of Mechanical Engineers and arrangements have been made for actively carrying it on.

Use of Pulverized Fuel.—The fight between the stoker-fired furnace and pulverized coal furnace has been merrily going on in the past year, the former being the more usual type, a sort of established method in the field of power generation, while pulverized coal is playing the part of the young but successful aggressor. At first the honors were with the stoker, the employment of pulverized coal, especially on a large scale, though successful for many years in cement kilns, having been attended with some trouble when applied to power plants. These troubles, however, have been largely eliminated and there is no question as to the brilliant future of pulverized coal in the field of large power plants. In the past year several plants of great capacity have adopted it as a fuel. The Baldwin Locomotive Company installed powdered-coal firing in place of oil firing, not because the latter was technically unsatisfactory but because the supply of oil proved to be irregular and lacking in absolute certainty. The Rummelsburg Central Station near Berlin, the largest central station in Germany, has adopted pulverized coal because with this method of firing it could use any coal that it found obtainable.

Improvements in the use of pulverized fuel have brought about the use of refuse fuel, of which there are many millions of tons lying around all coal-mining districts. Efforts in this direction have been particularly active in England. At the Nechells Central Station, Birmingham, fuel from the pit heaps is being burned, notwithstanding the fact that it contains up to twenty per cent. of ash and less than nine thousand B. t. u. per pound, which means a very low-grade fuel indeed. A still worse material containing up to thirty per cent. of ash is used at the Philadelphia power plant in Durham.

Benson Burner.—As usual there have been several types of new steam generators proposed, and intensive work was done to develop some previously known. Among these latter the Benson Burner is worth particular mention. Though proposed several years ago it has been first tested on a commercial scale in the past year and is now earnestly being developed in England and especially in Germany. In this boiler water is supplied under a pressure of thirty-two hundred pounds to the square inch and heated in the top of the boiler to a little over 900 degrees Fahrenheit. This pressure and temperature were selected for the reason that when this combination is used the steam occupies exactly the same volume as the water. There is, therefore, an evaporation without change of volume and no absorption of latent heat. Moreover, because of the poor heat conductivity of the water it is possible to maintain steam in the top of the boiler and water in the lower part. Tests made with this boiler at Rugby, England, have indicated the possibility of attaining a quite unusual efficiency.

Other Generators.—The two other steam generators worth mentioning are: the Becker boiler and the generator of the Combustion Engineering Corporation. In the former there is no water content in the ordinary meaning at all. Completely atomized water is injected into the pipe system and immediately transformed into steam. The flash boiler effect is, therefore, attained and the boiler is particularly applicable wherever steam is needed only at certain times; because of the rapidity with which steam can be raised it may also be used for taking care of peak loads. In the second steam generator referred to above, pulverized coal is burned under extremely high temperature conditions. The combustion chamber is in the shape of a rectangular box set on end with the sides of the box made up of boiler tubes. The spaces between the tubes have fins providing an air-tight enclosure. The pulverized-coal burners are located in the corners of the box and to raise the temperature of the flame are supplied with air specially preheated. It is claimed that the gases coming from the burners have a whirling motion around the chamber. From there they pass downward into a so-called settling chamber and on the way heat more boiler tubes. It is claimed that this construction results in the evaporation of 35 pounds of steam per square foot of heating surface, a very unusual output.

Last year at Hartford, Connecticut, was installed the first commercial mercury-vapor boiler and turbine developed by the General Electric Company. In this unit heat is applied directly to the evaporation of mercury which drives a turbine. Mercury vapor is then condensed in the same manner as water vapor with this distinction, however, that because of the high temperature of the mercury vapor the condensed water is in its turn evaporated and the steam is used to drive an ordinary steam turbine. There are, therefore, really two circuits and theoretically the efficiency of the plant ought to be very high, the output of the steam turbine being largely a by-product of the operation of the mercury-vapor part of the unit. That the principle of operation of this kind of plant is correct is indicated by the fact that in the past year efforts have been made to apply the same arrangement to marine boilers.

OIL ENGINES

Important Progress.—While there have been no unusual developments in the field of oil engines in the last year, there has been a large amount of solid and valuable progress. The growing recognition of the important field that the oil engine came to occupy in modern industry was well illustrated by the Oil and Gas Power Week in April, 1925, organized under the auspices of the American Society of Mechanical Engineers in association with a number of other prominent engineering organizations.

The most talked of progress of the oil engine was in the marine field. The U. S. Congress placed at the disposal of the U. S. Shipping Board twenty-five million dollars to be used as a revolving fund for making loans to operators of Shipping Board vessels desiring to reconstruct them into motor ships. This was done because it was recognized that the so-called Class A vessels have no chance of making money with the present steam propulsion, but would pay if equipped with the more economical Diesels.

Ship Conversion.—In Europe particularly has there been great advance in the application of Diesel engines in ship building. Not only enormous freighters were converted into motor ships or built as such, but Diesel drive was applied to passenger vessels, among them some of very large capacity. The most notable are the 22,000 ton *Aorangi* and the Swedish American Line vessel *Gripsholm*, the latter to be used in the New York-Sweden trade.

With the growing knowledge of the operation of Diesel engines there has been a material increase in the size of the engine output per cylinder and more expert design of the details until now the reliability of Diesel drive on shipboard is in no way inferior to that of steam operation. So great, in fact, has become the threat of the oil engine in the shipbuilding industry that the builders of steam turbines who were at first inclined to be quite complacent about the situation have become alarmed and are vigorously developing new types, with unusually high steam pressures and new cycles as a means of competition with the rival power.

Engine Design.—In the design of the oil engine itself there has been comparatively little radical new development, the attention of engineers being primarily concerned with the improvement of the existing types for which a growing market has already been created. One or two of the new types put forward in the last couple of years have been tested and some have been found good. Thus reports of tests on a vessel equipped with the North British engines with sliding cylinders, which were considered a daring innovation, proved them to operate in a satisfactory manner. Of the new developments the following deserve particular mention: at the Beardmore Ship Yards in England an attempt has been made to build a crude-oil aircraft motor. This motor works essentially on the Diesel principle with fuel injection, but is also equipped with high-tension ignition. At 1,200 r.p.m. the engine, which weighs around 1,800 pounds, is supposed to deliver 800 horse power. (This output is, however, for gasoline as fuel, all data on the output with crude oil as fuel being withheld from publication.) Another motor of similar construction about which the greatest secrecy is preserved is said to contain eight cylinders in line and deliver 1,050 horse power for a weight of 2,354 pounds. This is not encouraging as far as ratio of output to weight is concerned as there are now on the market excellent gasoline-driven explosion-type engines delivering a horse power for a little more than a pound of weight.

Modified Cycles.—In the field of modified cycles there have been two notable developments. A French engineer, Andreau, designed an engine in which the expansion stroke is considerably longer than the intake stroke. Such a design is justified by theoretical considerations and is said to give a motor of greater output than the conventional motor. The Andreau motor received official recognition from the French Bureau of Inventions.

W. Brown of Sydney, Australia, invented a double-expansion internal-combustion engine which has been tested both in Australia and in this country, and is said to have given an increase of nineteen per cent. in horse-power output with a fuel economy of seventeen per cent. An engine was also built in which, in addition to double expansion, triple and quadruple expansion can be obtained. In this engine the length of expansion is from two to four times that of compression, in addition to which an auxiliary chamber is used in which a well mixed expansive mixture is prepared for later use in the main chamber.

Crankless Engines.—Further progress was also made in crankless engines. The Almen barrel-type engine for use on automobiles was tested by the United States Navy authorities and found to be promising of important results. A 150-horse-power crankless oil engine was shown at the Marine Show in New York, but this has not yet been run under its own power. On the other hand, a 100-horse-power Michell engine designed by A. G. M. Michell (the inventor of the Michell blocks, extensively used with marine turbines) has been run under test at the University of Queensland and is said to have given very satisfactory results. The great advantage of crankless engines, providing a full and satisfactory reliable performance can be obtained, lies in the fact that they may be built so as to be substantially free of vibration and are expected to be economical in respect to fuel consumption. Another novel type of engine is represented by the one invented by W. H. Smith Whaley and built by the Sun Shipbuilding and Dry Dock Company. This engine differs from other heavy-oil engines by the fact that the cylinder clearance at the time of the fuel injection is opened by a piston valve communicating with a static receiver having many times the capacity of the cylinder clearance, the piston valve staying open as long as the fuel is being injected. It is claimed that by these means a much greater output and more economical operation are secured. A single-acting four-cylinder two-cycle machine rated at 750 horse power has been built and it is said that it weighs only about 90 pounds per horse power, a figure which would represent a substantial improvement on the current practice in marine engine design.

Materials for Cylinders.—In the past Diesel engine designers had to contend with the difficulty of finding proper materials for cylinders. Ordinary cast iron did not seem to stand up under the combination of temperature and stresses which were encountered in the operation of Diesel engine cylinders and there were certain objections, not insuperable, but serious, to the use of steel cylinders. Judging by information which is coming through from England there is a chance that this particular problem will be solved by new types of cast iron, among others by so-called Perlit cast iron which is cast in carefully pre-heated moulds from a melt containing definite proportions of carbon and silicon. This is but one of the instances where mechanical engineering is materially assisted by progress in metallurgy and chemistry. Other instances of this coöperation between science and branches of engineering will be indicated in the sections dealing with fuels and motor-car engineering.

FUELS

Fuel Resources. — Fuel consumption of modern industrial nations and in particular the United States which is foremost in this respect is becoming so enormous that grave doubts are entertained as to the ability of the resources in sight to satisfy them long. Not only this, but with the demand for fuels growing at an unprecedented rate the prices are also tending to increase alarmingly. Some thirty years ago gasoline was a drug on the market and was treated by oil refineries as a nuisance to be got rid of. Today if it had not been for the so-called cracking processes which permit to double the amount of gasoline recovered from oil there would not have been enough to go around. Furthermore, the Diesel and other types of oil engines are rushing in, making demands on the same sources of fuel which are needed for motor vehicles and possibly coming aviation. In America in particular oil firing has made substantial progress in steel manufacture and industrial firing. Of late it has been extensively adopted for heating in large office buildings and apartment houses and now, owing to recurrent shortages of anthracite, is beginning to make its way into domestic firing.

At the same time great improvements in power-plant engineering have made it possible to burn with substantially equal efficiency and economy practically any carbon-containing material (short of graphite); and lignites, brown coals, bituminous coal, both high and low volatile, semi coke and even coke can be burned in appropriate furnaces if only a reliable source of supply at a suitable price can be found.

Coal By-Products. — Under these conditions an effort to recover from coal the more valuable by-products, especially such as could be used in internal-combustion engines, has been natural. High temperature carbonization of coal, in which are recovered gas (such as would burn on gas stoves), tar, and residual coke, has been known for more than one hundred years. The efficiency of conversion in the high-temperature carbonization process has been, however, such as to make it impractical for any purpose except town gas manufacture. It has been found at a comparatively early date that by lowering the temperature of carbonization some 600 degrees Fahrenheit, it became possible to produce from coal ammonia (when the nitrogen content of the coal was sufficient), liquid oils (which were usable in internal-combustion engines and, as by-products), gas and coke (both of which could be applied industrially). Notwithstanding the apparent simplicity of the process, however, hitherto no complete commercial success has been attained, though in the past year a great step forward has been taken, largely because of a clearer comprehension of the principles and chemical reactions underlying low-temperature coal carbonization.

The Maclaurin process, the primary purpose of which was to produce a smokeless fuel, has been developed to the point where the Gas Department of the Glasgow Corporation is erecting a battery of five Maclaurin producers. In Germany low carbonization of coal in revolving retorts is already being practiced on a semi-commercial scale. The interesting feature in this German arrangement is that the coal retort consists of two drums, fresh coal entering at the bottom of the inner drum, passing up to the top and being pre-heated in the course of this operation. The actual carbonization takes place during the downward movement of the coal between the inside and the outside drums. In addition to this simple process in which coal alone is treated, other processes have been developed of a more complicated nature. In the Bergius process, powdered coal is subjected to high pressure and temperature with agitation in an atmosphere of hydrogen. This is done in several steps with the result that a partial reduction to motor fuel is obtained. Comparatively little is known as to the cost of this process and as to whether the motor fuel can compete with gasoline where it is as cheap as in this country.

The work on synthetic motor fuels has been ceaselessly going on in the past year. It is reported that Dr. Fischer, in Germany, succeeded in producing by the catalytic treatment of carbon monoxide under heavy pressure a fuel which he calls Synthol. Tests were made with it in a motor cycle and it is claimed that a good performance was obtained. The Synthol is really a mixture of various alcohols ranging from ethyl and methyl alcohols to the alcohols containing up to nine carbons. The production of this fuel is in many respects similar to synthetic production of methanol or wood alcohol which caused a good deal of excitement in this country in the early part of the past year.

Alcohol as a Fuel.—Increased attention is also being paid to the possibilities of alcohol as a fuel. In the United States this question is not arousing interest, first because of the availability of cheap gasoline and second, because of the obvious difficulties in distributing an alcohol fuel under the restrictive legislation resulting from the Eighteenth Amendment. In England, however, the question of producing a motor fuel from home grown materials is a very live one. The Jerusalem artichoke appears to be the most promising. From experiments made on a semi-technical scale by the British Department of Scientific and Industrial Research it appears that the yield of about 18.7 British gallons of ninety-five per cent. alcohol is possible per ton of tubers. Furthermore, by a bacillus process butyl alcohol and acetone (both valuable in chemical engineering) may be obtained. By a fermentation of the tubers by yeast and the action of an organism belonging to the bacillus butylicus, liquor is obtained consisting of seventy per cent. of grain alcohol, ten per cent. of acetone and twenty per cent. of butyl alcohol. It has been further found that by means of suitable treatment a cellulose can be prepared from artichoke stalks. Jerusalem artichokes can be grown in enormous quantities, not only in England proper, but in many of its colonial possessions.

LOCOMOTIVES

Steam Engines.—Up to a few years ago the steam locomotive had undivided sway in the transportation system and it looked as if the reciprocating engine of the type then existing (that means comparatively low steam pressure, simple design, with little attempt at economy in fuel) had come to stay definitely. Within the last few years, however, partly as a result of the rapid increase in the cost of fuel and also through developments in the power-plant field, signs have appeared that if the reciprocating steam engine wants to remain the chief type of power plant on locomotives it cannot do it without a fight. The electric locomotive has, of course, shown some very remarkable performances both in the way of economy of operation and ability to handle enormous loads over difficult grades. Today, however, it is not a very serious competitor of the steam locomotive because it would cost many billions of dollars to electrify the American railroad system and there is little likelihood that any attempt to do so on a broad scale would be now undertaken. There have been, however, other developments which are of vital interest to railroad engineers.

Within the last couple of years, in England, Ramsay and, in Sweden, Ljungström have built locomotives propelled by steam turbines and the Swedish locomotive not only successfully operated on home railroads, but found its way experimentally on to some of the foreign systems (e.g., Argentina). Last year, the Krupp Company in Germany also entered the turbine locomotive field and while none of these has yet proved the claims made for the turbine locomotives, essential and promising progress has been made.

The reciprocating steam locomotive is threatened from another angle and that is by the oil-engine type. Referring particularly to American developments the following deserve special attention. The Ingersoll-Rand Company in coöperation with the General Electric Company have placed on the market an oil-engine electric locomotive, particularly adapted for switch service. This has been tested for a considerable time on the New York Central Lines and has recently been adopted to some extent by other railroads. The Baldwin Locomotive Works also entered this field with a locomotive equipped with a Knudsen engine and other locomotive companies are experimenting with the same idea.

Locomotive Improvement.—It has often before happened in engineering that makers of a certain design were jogging along without any sincere attempt at improvements simply because there was no competition. When competition arose an effort at improvement was made and the industry was benefited. The introduction of electric light largely served to eliminate the old flickering open gas flame and to replace it by the beautiful incandescent mantle flame. The same is happening in the locomotive field. On one hand greater attention is being devoted to the three-cylinder locomotive type which until comparatively recently was not looked upon favorably by many engineers. It has been shown, however, in tests made by the Pennsylvania Railroad for the Missouri Pacific that the three-cylinder locomotive is much better balanced than the old two cylinder and promises to be more economical in operation. A still more radical step in the same direction was taken, however, by the Delaware and Hudson Railroad with the Horatio Allen locomotive in which the pressure of 350 pounds as compared with the former standard pressure of 200 pounds is used. It is calculated that the use of the higher pressure will save about one-third of the fuel now used on locomotives of similar capacity. The locomotive has already been tried in both passenger and freight service and has given every proof of being a development carrying great promise.

A test made last year shows the high stage of reliability which modern locomotives have reached on American railroads. A locomotive recently made the run from Harmon, thirty miles north of New York, to Chicago and return with no other attention given it than supply of fuel, water and oil. On some railroads locomotives are regularly taking runs of over five hundred miles without being detached from the train.

Locomotive Size.—Already several years ago a claim was made that steam locomotives have reached their ultimate dimensions. The width of the largest locomotives used and the height have become such that nothing more could be added without making it impossible for the locomotive to pass through existing tunnels. So great was the growth of the locomotives upwards that the stack has practically disappeared, at least with the locomotive seen from the outside. The present indications are, however, that in at least one direction in which there doesn't seem to be any limit, the locomotive continues to grow, and that is lengthwise. The Garratt Locomotive, built in the past year for the London and Northeastern Railway, is an enormous machine consisting of two 2-8-0 engines, each of the three-cylinder type. The boiler for this huge machine is seven feet in diameter and the tractive effort is equal to that of two ordinary freight-train engines. The locomotive is to handle trains weighing about 1,000 tons on a sharp upward grade (with 2 miles at 1 in 40 up) and is to replace three working engines used at present.

Another enormous machine is the modified Fairlie locomotive built by British works for the South African Government Railways. This is a locomotive of the articulated type and consists of two units working as bogies carrying a cradle on which is mounted a boiler. This locomotive again is to haul enormous trains over difficult grades (over some parts of the line the grades are 1 in 55 with 528 feet radius curves).

MOTOR CAR ENGINEERING

Balloon Tires.—The past year was both fertile of new developments and promising of still greater developments in the automobile industry. The introduction of the balloon tire in the previous year has brought a whole flock of new problems to the automobile engineer. One of these had to do with the tendency of balloon equipped tires to "shimmy," which means, to obtain a side-to-side sway, especially noticeable to people driving in such cars for the first time. This problem has not yet been completely solved although better study of the subject of balancing has indicated how to handle it.

Compression Ratio of Engines.—During the war it was found to be necessary to increase the power output of aëroplane engines. One obvious way to do it was to raise the compression ratio of the engines, but when this was done various troubles developed, such as pre-ignition and a peculiar knock in the engine, both of which were found to produce ultimately with the higher compression ratio a lower output instead of a greater one. An investigation was started by the engineering department of the Air Service at McCook Field and the staff of the General Motors Research Laboratories, and several ways were found to combat pre-ignition and knock, the former by better cooling of the spark plugs and similar means, and the latter primarily by changes in fuel. It was found on one hand that addition of substantial amounts of such materials as benzol and cyclo-hexane eliminated the knock; on the other hand it was found that the addition of very minute amounts of such materials as iodine produced the same effect. Work was started in the latter direction and a number of substances, some of which were known only as laboratory curiosities, were tried. Ultimately it was found that an alkyl, tetraethyl of lead, had the best result in the elimination of the knock and permitted to use much greater pressures without bringing the engine into distress. This opened visions of smaller and more powerful automobile engines capable of giving perhaps as much as forty per cent. more miles per gallon, and the tetraethyl of lead for a while looked like the beginning of the biggest revolution that the automobile industry has seen.

Then a fog of doubt was dramatically cast over this situation. Some three score of men in the factories of the Standard Oil Company of New Jersey and the DuPont de Nemours Company, making tetraethyl of lead, became poisoned by the lead emanations and developed symptoms of lead insanity. Some of them died, others partially or fully recovered, but the matter created a tremendous stir in the press with the result that a conference was called by the chief of the Health Service of the United States and a committee appointed to investigate the subject of safety of use of tetraethyl of lead in gasoline. This committee has not yet made its report at the time of this writing. In the meantime, however, the sale of "lead gasoline" has been voluntarily stopped by its manufacturers.

Gear Shifting.—One of the nuisances of automobile running, namely, gear shifting, seems to be on the way to elimination. Several devices have been recently proposed, chiefly in Europe, and have shown sufficient promise to indicate that the time is not far off when the present gear shift will be done away with.

Air and Oil Cleaners. — Supercharging has become a practically standard part of the racing automobile. It does not seem, however, that at least in its present shape, it may be applied to commercial cars. On the other hand, there has been a remarkable increase in the adoption as standard equipment of such devices as air cleaners and particularly oil cleaners. This latter is going to contribute materially to increasing the life of the engine and helping maintain it in good condition. There has been also increased attention given to the matter of vibration which led to the adoption of crank-shaft balancers by several prominent manufacturers.

HYDRAULIC ENGINEERING

New Hydroelectric Developments.—Just prior to the war the practice in water-turbine design seemed to have been completely standardized. It would be too long to tell the reasons for the change that came about within the last few years. The result was, however, that the development of this art has taken on new life and has already been revolutionized in many respects, with other and perhaps still greater changes coming. Hydroelectric engineering in America has attained a surprisingly high stage of development. The efficiencies which are regularly secured today under operating conditions by both the water end and the electrical end of the plants are truly amazing. The Niagara Falls Power Company installed a 65,000 kilo-volt-ampere generator driven by a 70,000 horse power hydraulic turbine with a guaranteed efficiency of 98.1 per cent. at full load on the generator, and tests have shown that this guarantee is well maintained. The machine has a total weight of 1,500,000 pounds and the total height from the floor to the top of the generator is 26 feet and 4½ inches. So big and heavy is the machine that it had to be assembled on the spot as there was no way of transporting it from the factory and the wheels have for a short period actually developed 84,000 horse power.

Muscle Shoals.—At Muscle Shoals a hydroelectric installation is under way, and its total capacity will amount to 610,000 horse power which will make Muscle Shoals the most powerful hydroelectric station in the United States. Four generators are now built for that plant with a rating of 32,500 kilo-volt-ampere designed for a guaranteed efficiency of 97.9 per cent. at full load. One way of giving an idea of the size of these generators may be stated by the fact that approximately 100,000 cubic feet of air per hour will be required for cooling each unit. At the Minnesota Power and Light Company's new hydroelectric development on the St. Louis River there has been put in an unusual type of vertical generator. Notwithstanding the fact that it is to develop 15,000 kilo-volt-amperes, the whole plant is built with an idea of making it a one-man station, the operating room being so arranged that the operator can watch the governor, exciters, auxiliaries and various gauges in connection with the generator unit.

High Efficiencies.—The remarkably high efficiencies both at the generator end and the hydraulic wheel have not just "growed up" like Topsy. They were the result of expensive research, of hard work and introduction in modern installations of a number of refinements in the design of the main plant and auxiliaries. There are no data available to enable one to make a comparison of the cost per kilowatt of modern installations and the less efficient plants of ten years ago. That this cost has gone up not only because of the general rise of price level, but because of the more elaborate equipment of the modern plant there can be no question. On the face of it it would appear that this greater cost is commercially justified as otherwise the new types of plants would probably not have been adopted, and yet one cannot help wondering as to whether or not we have gone too fast in an effort to obtain maximum efficiency, possibly at the cost of losses elsewhere. For example, it would appear that in many places slower and cheaper turbines might have done just as well as, if not better than, the faster types on which the buyers of the equipment insisted.

There has been also a growing feeling that unnecessarily elaborate governing devices are installed in modern hydroelectric plants with the result that not only is the cost of the installation inordinately increased but even the chief purpose of governing, that is, securing uniform and safer operation, is defeated at times where the governors are made too sensitive.

REFRIGERATION

Better Operation in Plants.—In this field a large amount of work was done towards the improvement of operation of existing plants. While in no wise spectacular it is unquestionably useful and will save the consumers in industry considerable sums. The most important has been along the lines of further investigation of the thermodynamic properties of ammonia vapor carried out principally by the United States Bureau of Standards.

Industrially this year has seen the definite coming into its own of the domestic refrigeration. Domestic refrigeration apparatus has apparently reached the stage of perfection, in the way of economy of operation and reliability, where the companies are no more afraid of pushing its sales on a large scale. While there are still many difficulties in the way, chiefly of a commercial nature, there is little question as to "ice by wire" having seriously come to threaten the business of the iceman. All of this domestic refrigerating machinery is electrically driven and operates with heat exchange media which are non-explosive and non-poisonous.

New Apparatus.—The only significant development in the way of new apparatus is the Platen-Munters refrigerator, of interest because it has no moving parts at all. The only motive force for the whole apparatus is derived through the heating coil and by the application of heat to this coil the refrigeration desired is obtained in another portion of the machine. There has not been sufficient experience with this device yet to determine how it compares with the more standard refrigerating apparatus (compressor operated) in the way of economy in apparent consumption and reliability.

AUTOMOTIVE ENGINEERING

By H. L. Horning
Waukesha Motor Company

Engines. — In automobiles and trucks, two cylinder engines have practically disappeared, there being one very successful two cylinder engine, and four cylinder engines are giving way to six cylinder engines in trucks in some services. This tendency has developed in all sizes of equipment. The year 1925 may be designated as the six cylinder year for during this period marked inroads have been made by small six cylinder engines into the sales of four cylinder cars, and the cost of production of small light speed six cylinder engines has been brought into close competition with fours. On the other end of the scale, automotive engineering has made great strides in producing reliable high speed sizes, of a large size, for motor buses and rail cars. These engines of high horse power are essential to meet the demand of the public for bus service equaling motor car performance.

Tendencies.—The general tendency of design has been towards smaller, high speed engines, lower ratio of rear axle to engine speed and towards six cylinder engines. Cast in one piece cylinder and crankcase is prevalent in motor car engines, and buses. The tendency is towards detachable cylinders, cylinder heads and very deep crankcases. Crankshafts are growing in size and stiffness and bearings are large in diameter but shorter in width and in many cases the stiffness of shaft has not only resulted in much smoother running, but also in the satisfactory operations of crankshaft, main and rod bearings of much less projected area. The force feed lubrication through the shaft is growing in popularity and is almost a standard among the better and moderate priced parts.

There is a distinct tendency away from long stroke engines where smoothness of running, reliability and low cost are desired. Developments in better shaped combustion chambers make this possible and the difference in economy and power of long stroke versus short stroke and small versus large engines has been wiped out by considerations of better mechanical design and a better application of the laws of thermodynamics. The public demand is for high acceleration and deceleration. The engineers have met the acceleration by the adoption of high compression, compact high turbulence head engines, hot spot manifolds and carburetors giving high power mixtures for acceleration purposes and at full load and high rear axle ratios and low vehicle weight.

Fuels.—Automotive engineering has for the past decade given great study to this process of combustion in the cylinder of the engine as a hopeful means of increasing the power output and economy of operation. During this year effective efforts have been made to market fuels which were the results of the highest order of research. By the addition of many kinds of stabilizers, which the Automotive Industry has discovered, the present fuels have been prevented from developing explosive waves in cylinders of engines. The marketing of anti-knock fuels is preparing the way for engines of higher compression; thus taking advantage of the higher efficiencies to be attained by higher expansion ratios.

The year 1925 sees the dawn of the day of Diesel engines for all services. During this year there have been many new developments in this type of internal combustion engines. With the rapid development of the sciences of chemistry and physics there is a growing understanding among engineers of the process of combustion and the laws of thermodynamics, and sub-atomic physics is pointing the way to the most outstanding developments in internal combustion engines of the second quarter of the Twentieth Century. Today the highest thermal efficiencies of these engines approach 38 per cent. whereas in common practice motor cars go as low as 5 per cent. utilization of the energy of the fuel. Developments of the year in our best laboratories indicate that soon it may be possible to attain efficiencies on the road of 15 per cent. to 20 per cent.

Gasoline. — The Society of Automotive Engineers has through a coöperative fuel test conducted over the last five years by the United States Bureau of Standards and with the support of the American Petroleum Institute and the National Automobile Chamber of Commerce, developed important facts concerning the availability of power from commercial gasolines and these tests have pointed the way to modification in the specification of gasoline which has resulted in vast increases in the supply of gasoline from the available crude. Through these researches in fuels the general methods of production of gasoline have been indirectly affected and gasolines of greater utility are being produced. During these tests 1,000,000,000 gallons of gasoline of a wholesale $100,000,000 value have been added to that available from the crude by old specifications.

Reducing Wear.—The greatest engineering advances have come about with the object of increasing the life of the wearing parts. Among these may be mentioned the growing use of air cleaners to remove dust from the mixture and to increase the life of cylinders, pistons and rings. Another improvement is the filtering of the used lubricating oil, thus removing the products of wear and combustion and oil disintegration. Means have been adopted for filtering the gasoline, thus the automobile engineer has gone a long way in 1925 to deliver clean oil, fuel and air to the engine. The engineers have learned, through the coöperative fuel tests, to control dilution of the crankcase oil and methods of removing this are common. Most engines are so designed and are being sold that dilution is not a problem in 1926 cars.

Clutches and Transmissions.—The multiple disc and single plate clutch are practically standard, the cone clutch having almost disappeared. In transmissions, no great improvements have appeared in motor cars, however, in motor trucks and buses, transmissions giving a wide range of ratios have brought about higher speeds of the vehicle without corresponding depreciation of engines. Due to a wide adoption of high gear ratios on buses these vehicles make gasoline and oil mileages, which were not possible for heavy cars a few years previous. This is a great development, although in motor cars the tendency is the opposite owing to the use of smaller high speed six engines; the necessity of low gear ratio has grown in the last year. A number of means are being developed to provide a noiseless over-gear and one of the great improvements pending in the industry is the general adoption of a quiet over-gear.

Tires.—Perhaps the most outstanding of all the recent improvements has been the balloon and semi-balloon tires. These have been widely adopted in the short space of three years and have added more than any one item to the comfort of riding on all roads and have made the small short wheel base car more popular than ever and hastened the day of the more general use of small cars. With the vast increase in automobiles and the gradually increasing traffic density, the increasing difficulty of maneuver in the cities and the increasing mileage of good roads, the day of the small car has arrived and the balloon tires are making it increasingly popular. While the comfort has greatly added to the popularity of the balloon tire its greatest usefulness is in preserving the mechanism of cars from the road shocks. It never will be known how much this has added to the life of cars and the car mileage, and the economic value is beyond the wildest guess.

Rear Axles.—There has been no great advance in rear axles, but all types of vehicles are being suspended on better springs. Better riding qualities are being developed on all sizes of vehicles and a great improvement has been made, particularly in small short wheel base cars. The widespread use of four wheel brakes has also marked the public demand for high touring and city speeds.

New Developments and Services.—One of the outstanding developments of the year has been that of motor buses, the production of these having practically doubled. Buses of all sizes and types have developed rapidly and there have been many failures of designs, much experience gained and several successful buses developed. Starting five years ago in city service, buses using 300 cubic inch engines and a 31 passenger capacity have grown in service to engines of 1000 cubic inch displacement and 60 passenger bodies, weighing empty 16,000 lbs. These buses have increased in speed from 25 miles per hour to 70 miles per hour.

Gas-Electric Buses.—One of the most interesting developments during the year is the use of gas-electric drives in buses and there have been several large installations of this type of vehicle. This development is in its infancy and much research is ahead of it. In this drive a generator is directly driven by the engine and the current from this is developed and fed to electric motors, propelling the rear wheels. The main objects of this type of drive are a smoother get-away, a quicker acceleration and an ease in handling. This type of drive appeals to the electric railway interests whose organizations are equipped through training to handle this type of apparatus.

The country has witnessed during the year a complete acceptance of the motor car, truck and bus as short haul utilities by railway interests, and street railway companies have taken up the bus and taxicab as a means of meeting the new order of things. Closely related to these developments is the steady growth of gasoline rail-cars for passenger service of short lines which appears certain to develop as rapidly as present equipment can be worn out. Motor boats are developing along all lines and power types of internal combustion engines and are used for many new services.

Statistics of Industry.—The year 1925 ended a quarter of a century in which the World's largest industry was developed. The automotive industry in America is the foremost in the World of all the great domestic industries. On January 1, 1926, there were registered in the United States, 20,435,000 motor cars and motor trucks and buses. During this year 3,883,000 motor cars have been produced and 420,000 trucks. The exports of American motor cars and trucks during 1925 have reached 540,000 units which together with the domestic market was the largest in the history of the industry in number and in value. The wholesale value of the products of the automotive industry reached the enormous sum of $4,500,000,000 in 1925.

Many industries have been revolutionized in earnings and output and character of product by the automotive industry. As a measure of these the following statistics cover a few of the commodities which are used by the automotive industry and its products:

12 per cent. of the total production of steel.
47 per cent. of the total production of aluminum.
54 per cent. of the total production of plate glass.
70 per cent. of the total production of upholstering leather.
82 per cent. of the total consumption of rubber.
16 per cent. of the total consumption of lumber.
8 per cent. of the total consumption of copper.

9.5 per cent. of the total consumption of tin.
10 per cent. of the total consumption of lead.
3.8 per cent. of the total consumption of zinc.
82 per cent. of the total consumption of gasoline.
55 per cent. of the total consumption of lubricating oil.

So we may go on and trace the influence of the automobile on good roads and the allied industries, and the general increase in transportation with its activities.

Passenger traffic between all adjacent cities has vastly increased and the traffic from country to city multiplied many times.

Economic Lessons of the Industry.—The reason for the very rapid growth of the industry has been the vast buying power of America and the wealth-producing power of the automotive products. There is no stratum of society which is not beneficially affected by the advent of automotive transportation. There are few industries on which the nation depends for its wealth which have not been speeded up and their earning power greatly increased by automotive products. Vast areas have been developed and made available for homes and the congestion of city dwellers has been solved, as well as the dwellers on the farms and remote sections of the country freed from their isolation. It is impossible to estimate the values added to suburban and farm land by the increasing use of transportation of motor car and truck.

Cost of Production.—The automotive industry has attained its greatest achievements by the perfection of low cost methods of production of intricate machinery and has led the world in proving the economic principle that vast improvements in cost invested in further time-saving devices and systems, together with lowering of prices to the public as fast as possible, broaden the market and develop an industry and ultimately bring greater profits than excessive unit profits. The industry has proven that the greatest utility is attained when every class can afford its products. There is no industry that has given the public so much for its money, and since the war the buying power of the dollar has gained 60 per cent. in purchasing automotive apparatus.

COMMERCIAL AVIATION

By Archibald Black
Consulting Air-Transport Engineer

General.—The most outstanding developments on the constructive side in aëronautics in 1925 have been the further pushing up of certain world records; continued progress in helicopter development; successful demonstration of anti-stalling devices for airplanes; further improvement in night-flying equipment and operations; the development of air-cooled engines of larger power than heretofore considered practicable; and last, but by no means least, the sudden awakening to the commercial possibilities of the airplane in the United States. On the negative side of the slate might be noted the destruction of the U. S. S. *Shenandoah*, with the loss of several lives, through unusually severe storm conditions during a flight over Ohio. This accident was a severe blow to the advocates of the airship for both military and commercial purposes but the effect will only be temporary. Airship designers are now studying the problems which this accident brought to the forefront. Work in the various fields of research affecting aëronautics has been constantly carried on throughout the world, the United States having rendered a very creditable account of itself in all branches.

Air Transport.—More or less steady improvement has been shown in the development of air transport throughout the world. This improvement might be credited mainly to the educational effect of continued operation rather than to technical advances in equipment. While constantly fluctuating, the volume of traffic generally tends to increase and a few of the European airlines are nearing the position of self support. In all countries other than the United States it has become the accepted policy to subsidize privately operated commercial air-transport routes. In this country, due largely to the prevalence of public opposition to the principle of subsidies, a different course has been followed. Instead of subsidizing private operators the government itself entered the field in 1918 with the initiation of an Air Mail Service by the Post Office Department. This service, which has been gradually expanded since its inception, does not cover its operating charges but it is regarded as a practical laboratory for the development of equipment and information on operating conditions. As such it is rendering a very useful service in addition to greatly advancing the delivery of certain mails. As the result of the European and American policies regarding the development of air transport, Europe has many privately operated and few government routes while the United States has very few privately operated lines but a very active government-operated Air Mail Service. Compared upon a rational basis, that of mileage flown, in the absence of any better one, this country stands about first or second among the nations of the world. This is, of course, contrary to the prevailing impression created by comparisons on the basis of numbers of routes rather than their operations.

Significant Air Transport Developments. Early in 1925 the Ford Motor Company, which had been interested in aëronautics since 1918 or 1919, started the operation of some airplane routes between certain of its plants. This move was followed closely by the announcement of plans of a group of nationally known business men to enter the air transport field on a large scale under the name of National Air Transport, Inc. The two announcements appeared to take hold of public sentiment in a manner never before possible, and very important moves in airline development are indicated as a result. Among those directly resulting from this change of sentiment was agitation for the establishment of air routes for the transport of mail, packages and possibly passengers, under the terms of the Kelly Bill. Responding to this expression the Post Office Department planned the establishment of eight such routes for 1926. Up to the present, contracts have been awarded for operation of five of the proposed lines while others are under consideration. Thus the United States seems assured of the creation of a comprehensive system of air-transport lines immediately.

Night and Fog Flying Equipment.—The most noteworthy work in the field of night-flying equipment is probably the development of electrical apparatus of lower initial cost combined with some improvement in reliability. Experimental installations of fog-piercing lights have been installed and are now being tested in the United States and England. The results are said to be very promising but the work has not yet reached the stage where final conclusions can be drawn. The question of fog being of greater importance in operations in England than in most other countries, particular attention is being given to this problem over there. In addition to the fog-piercing lights alone, experiments are planned using a combination of radio direction finding equipment for locating the landing field and fog-piercing lights for effecting the actual landing. During the year the U. S. Air Mail Service placed in operation its night service between New York and Chicago. While this was not the first scheduled night operation of the U. S. Air Mail Service, it is of particular interest on account of the difficulties involved in the territory flown over. A portion of the route passes through the Allegheny mountains and over some closely wooded areas. While marred by one accident during the several months of operation to date, this route has marked a very important advance in commercial aviation.

Airplane Design and Construction.—Some new types of commercial airplanes were produced which are worthy of special reference. Fokker turned out a three-engined monoplane for passenger or package transport, following his customary construction of plywood wings and steel tube fuselage. This machine is equipped with Wright air-cooled engines and is indicative of the recent trend toward the air-cooled engine in commercial operations. De Havilland, Roe and Beardmore were each active in England in the production of new designs for transport use, while in France Farman continued the "Jabiru" type which has been used on some of the French air routes. In the United States the Curtiss Company developed the "Carrier Pigeon," a transport type for mail and package carriage which is of particular interest because of its adoption by National Air Transport for its proposed routes here. The British are at present working on the design of a freight-carrying airplane to have a carrying capacity of 8¼ pounds of actual pay load per horsepower. This is worthy of note as marking a very important advance over present types which seldom show better than some 4 or 5 pounds. Certain of the military productions are of some interest in connection with civil activities, one of the notable productions in this class being the Loening amphibian. This design incorporated several unusual features including an inverted engine installation. While the inverted engine installation is not entirely a new idea it is one which has been given very limited consideration previously. Having many advantages, particularly from the viewpoint of propeller clearance and visibility, this arrangement is likely to become more popular among the airplane designers in future. The Curtiss 1925 Pulitzer Racers and also the Gloster-Napier, Supermarine-Napier and the Macci Schneider Cup Racers are all either military designs or have a strong military tinge. Yet they are of some interest in connection with civil activities through pointing the way to further reduction of resistance and consequent increase in speed.

Airships.—Activity in the airship field was marred by the loss of the *Shenandoah* previously mentioned. While there is no doubt that airship development will be seriously affected by this accident, the work will certainly be carried on. It seems questionable if rigid airships can be designed to withstand such extreme conditions as the *Shenandoah* encountered but the accident will result in provision of greater strength and more power in future designs. The combination of the two changes will go toward eliminating the danger of a repetition of the accident. While the increase in strength will allow the airship to withstand greater storms, the increased power will enable it to avoid storm areas more readily. As indicating the continued faith in the rigid airship, the Bureau of Aeronautics is understood to favor appropriations to continue its work in this field while the British have given no indication of abandoning their stupendous airship operating scheme. In the meantime work on non-rigid and semi-rigid airships is being continued unaffected by the disaster. One of the interesting developments of the year in the airship field was the design and erection of a novel form of airship mooring mast by the Ford Motor Company at Dearborn, Mich.

Engines.—The most striking development in the engine field is probably the marked return to favor of the air-cooled engine. This type is now being developed in sizes which would, a few years ago, have been considered well beyond the practicable size for adequate cooling. The tendency is toward still larger sizes and the near future will probably see the production of air-cooled engines developing well over 500, and possibly over 600, horsepower. Both in the United States and in Europe this type of engine has already been developed in sizes up to 400 horsepower and the larger units in this range are undergoing service tests. Important advances have been made in extending the life of all types of engines and some airplane engines are known to have been in service, with the usual overhauls, over 1,350 hours. This is equivalent to about 135,000 miles of flying. A considerable amount of experimental work and research is being carried out on various engine problems. Several very novel types of internal combustion engines are being tested to determine their practicability and attempts are being made to develop heavy oil engines of the Diesel type for aircraft use. A sleeve valve engine of 450 horsepower has been built experimentally in England and is being tested. Reduction in the weight-horsepower ratio has been constantly carried on and some very successful American designed and built engines weigh as little as 1.2 and 1.32 pounds per horsepower. As a direct result of the outstanding success of American designers, the United States is now exporting instead of importing engines. The recognition given to our leadership in this regard is even more strikingly shown in the number of foreign transport and racing types which are being equipped with American engines.

Miscellaneous.—Instrument development has been carried on to keep pace with the development of aircraft and air speed indicators are now available which read up to 350 miles per hour. In the United States the vertical form of airplane instrument is coming into favor and this type allows the use of a very compact arrangement on the instrument board. In the field of aërial photography technical progress was made chiefly along the lines of greater independence of lighting conditions, greater camera range and increased accuracy in surveying and mapping. The stereoscopic method of obtaining elevation contours from aërial photographs has now reached the stage where a high degree of accuracy is obtainable. In the field of wind-tunnel research a large volume of additional information has become available but this took the form of small advances throughout rather than any outstanding or radical improvements. However, the development of still higher wing lifts through the use of auxiliary flaps, etc., is worthy of mention, as are also the experiments with vertical fins placed near the tips of the wings which were found to increase lift somewhat.

WORLD AIR TRANSPORT IN 1924-25

MILEAGE OF SCHEDULED SERVICES OVER TWELVE-MONTH PERIODS AS NEARLY AS POSSIBLE COMPARABLE.

Country of Registry	Miles Flown	Remarks
Australia	262,895	
Belgium	160,000 *	
Great Britain..	890,000	
Canada	294,778	Includes some non-scheduled operations.
Colombia	169,500	
Czechoslovakia.	126,400	
France	2,249,000	
Germany	1,860,000 *	Considerable duplication of mileage included.
Hungary	225,410	
Italy	No lines running in 1924	
Netherlands ..	482,800	
New Zealand ..	6,352	
Poland	124,203	
Soviet Russia..	288,600	
Sweden	69,280 †	Unofficial estimate.
Switzerland ..	268,400	Considerable duplication of mileage included.
United States..	2,220,761 †	Including air mail service but no non-scheduled operations.
World total .	9,698,379	

All data from British official reports except as noted.

* F. B. Austin in *Saturday Evening Post*, 1925.

† Estimated from miscellaneous sources.

Non-scheduled mileage in U. S. estimated at 857,048 additional; in Great Britain 139,000 additional; figures not available for other countries.

RECENT OUTSTANDING WORLD RECORDS

COMPILED BY E. L. JONES.

(No important changes in balloon or airship records.)

NAVAL ARCHITECTURE AND MARINE ENGINEERING

By James Swan

Editor of "Marine Engineering," New York

Conditions.—The extreme depression in world shipping which has prevailed practically throughout the past year has had the effect of reducing commercial shipbuilding to the lowest point it has touched in many years. In addition to this, the disarmament agreement has resulted in taking away from the larger shipyards that which, in America, at least, has been a chief source of income,—the building of large naval vessels. As a result of this condition, many of the yards have devoted their energies to the acquirement of such outside work as their equipment was capable of handling; structural work, forgings, hydraulic turbines and the like; with the result that progressive development in naval architecture and marine engineering has been practically at a standstill.

It is a general experience that in such allied sciences and arts as naval architecture and shipbuilding temporary periods of slackness are taken advantage of for carrying out research or experimental work, not possible when business demands occupy a plant's full capacity. Ships, however, are too expensive to be built for experiment alone; their building must have some commercial justification behind it. While a new vessel may embody certain experimental or tentative features, the transaction of her building is and must be essentially commercial.

Diesel Engines.—Notwithstanding the general adverse conditions which have surrounded it, shipbuilding and engineering have made material advances during the past year. Without doubt the most outstanding feature has been the continued and steadily expanding adoption of Diesel engines for ship propulsion. Heretofore confined in the main to relatively low speed vessels of moderate power, the past year has witnessed the completion of several motor-propelled ships of the ocean liner type, some of them equipped with machinery of over 20,000 collective shaft horsepower. While these vessels have been in service but a short time and their commercial success can only be satisfactorily and finally determined from operating experience extending over a much longer period, the results so far obtained are reported to be eminently satisfactory and there seems to be little reason to doubt that the motor liner has come to stay.

The eventual success of any particular ship must, in practically every case rest upon her overall commercial efficiency; in other words, the first cost with its resulting yearly charges, for interest, depreciation and insurance must enter into the picture as well as the actual operating costs and the savings which may be realized as the result of using some particularly economical form of machinery, such as the Diesel engine.

In this respect, the Diesel owing to its relatively high first cost, has been at somewhat of a disadvantage. While for long voyages at low power it has shown remarkable results, from both the engineering and commercial points of view, on shorter trips with a larger percentage of time spent in port, its advantages are not so apparent. Up to the present, practically all Diesel marine engines have been of the single acting type, a fact in part responsible for their relatively high weight and cost per horsepower developed. So long as powers remained small, this presented no very serious difficulty; but for such large powers as are necessary for passenger liners it became a very great, if not insurmountable, obstacle in the way of the commercial success of this type of machinery. The solution of this difficulty has come, in part at least, with the development of the double acting Diesel with a much larger output per unit of weight and cost than is possible with the single acting type.

Reduction Gears.—The preceding remarks apply to relatively large and heavy engines, coupled directly to the propeller shaft. Recently a number of vessels have appeared in which small, fast running motors, drive the propeller shaft through the medium of mechanical gearing or electric generators and motors. The former type of drive has been considerably developed in Germany, and to some extent in this country. Some form of flexible coupling or hydraulic clutch is advisable, between the motor and the gears, to eliminate shock and torsional vibration, but this system is nevertheless probably the cheapest form of Diesel drive, so far as first cost is concerned. The electric reduction gear has been highly developed in naval work in this country in connection with steam turbines. For services requiring economy at widely varying rates of speed, it is undoubtedly well adapted and offers great possibilities for the future.

More recently electric reduction gears, in conjunction with small Diesel engines, have come into prominence. This system is being highly developed in this country, although the largest power installations so far made are to be found in three fruit steamers built in Great Britain. It is particularly suited for tow boats, owing to its unrivaled maneuvering qualities, and has already been fitted in a number of American vessels of this class, with more in prospect. The Diesel electric drive also offers advantages where considerable power is used for other purposes than propulsion, as in refrigerator ships and oil tankers. Two American oil tankers, fitted with this type of machinery have entered service during the past year, and are reported as being very satisfactory and efficient in every way. Diesel electric drive has been or is being installed in a number of American yachts, formerly propelled by steam power.

Economy of Machinery.—While great advance has in past years been made in the economy of performance of marine steam plants, it is a well known fact that they have been outstripped in this particular by the large shore power stations. This has been due in part to the natural and justifiable conservation of marine engineers, but mainly to the fact that many of the methods in common use on shore are, in their present form, entirely unsuited and impracticable for installation on shipboard.

The rapid advance of the Diesel engine has brought to marine steam engineers, with renewed force, the necessity of increasing the economy of their machinery. As has been already remarked, the cost of Diesel engines, even of the double acting type is high, per unit of power produced, and the question arises whether, in view of its relatively low first cost, the marine steam plant, by the adoption of certain shore powerhouse devices and practices may not be brought reasonably close to a Diesel plant, in overall efficiency.

The path, as pointed out by stationary engineering practice, leads to high steam pressures and superheat, high vacuums and improved condensing apparatus, "stage" feed heating by steam withdrawn from the turbines, reheating of the steam itself and the effective utilization of the waste heat in the boiler uptakes, either for preheating the furnace draft or for feed-water heating.

With the exception of stage feed heating and steam reheating, all of these means of effecting economy of fuel are in more or less limited use in marine plants. High steam pressures predicate the use of watertube boilers. These are already extensively used though not as yet at the pressures obtaining ashore. An American cargo steamer recently completed, uses steam at 250 pounds and 150 degrees superheat and is showing excellent results, though still materially below those of the best shore plants. Additional vessels are contemplated to use steam at 350 pounds and 200 degrees superheat by which a further and material saving will be effected. High vacuums are steadily maintained at sea, but the condenser becomes a constant source of trouble owing to the salt cooling water, since with the high pressure watertube boilers, pure, fresh feedwater is essential. It seems probable that before much higher pressures can be successfully and continuously used at sea some certain means must be devised to produce leakless condensers and thus prevent any salt water from finding its way into the feed system.

Stage feed-heating and steam reheating are entirely practical for machinery running constantly under a given load. Ship machinery runs at varying speeds and has to be frequently reversed and maneuvered. While this may not present insurmountable difficulties, the fitting of such devices would materially add to the complication and crowding of the machinery and therefore appears of doubtful utility from a practical standpoint.

Turning to the utilization of waste heat in the furnace gases, it may be said that moderately heated forced draft has long been in use in marine plants but that recently developed devices pave the way to a much greater preheating of the furnace draft than has heretofore been considered practicable and their very general adoption seems probable.

Practical Application.—The extent to which the various methods outlined may be expected to improve marine steam plant economy, if utilized to the fullest practicable degree, is largely a matter of conjecture. Actual trial alone can satisfactorily determine what can and what cannot be done while at the same time preserving the reliability and ease of operation which are essential to satisfactory shipboard performance. To this end a contract has recently been placed in Great Britain for the construction of a steamer with machinery embodying most if not all of the devices which have been mentioned; the intention being to give them a thorough and exhaustive test under actual service conditions. It is the expectation of the designers of this ship and her machinery, and they are among the very best in Great Britain, that a shaft horsepower will be produced for 0.66 pound of fuel oil. The corresponding figure for a Diesel installation is 0.45 pound but the lesser cost of the steam plant, estimated at approximately 70 per cent. of the Diesel, is expected to largely offset the difference in operating expenses. This experiment is perhaps the most important, in its field, which has been undertaken since the introduction of the steam turbine for ship propulsion, something over 25 years ago, and its outcome is awaited with the greatest interest by shipbuilders and operators, the world over.

Pulverized Coal.—A most notable development in marine engineering during the past year is the work at present going on preparatory to the introduction on shipboard of pulverized coal as a fuel for generating steam. While this type of fuel is already used to a considerable extent ashore, the type of apparatus has been such that the resulting flame was too long to be effectively used in the relatively restricted combustion spaces of a marine boiler. Apparatus has now been devised whereby the flame is shortened without reducing its phenomenal heat-producing properties, and practical trial at sea only awaits the production of a satisfactory grinder for ship's use and the design of air supply and ducts to feed the powdered fuel to the furnace. As very low grade coal can be used and the heat liberation obtained is enormous, it appears practically certain that the marine use of pulverized coal fuel has before it an enormous field of usefulness. It is of interest to note that this development is a peculiarly American one, so far almost entirely confined to this country insofar as ships are concerned.

Contrapropeller.—Turning from the power plant itself, the most notable recent development in ship propulsion has been the practical adoption, in a number of merchant vessels, of what is known as the contrapropeller. In brief this is a device for applying to the ordinary marine propeller certain principles which have long been taken advantage of in water power turbines. By fitting stationary guide blades in front of or behind an ordinary propeller the wake, or water left behind the vessel as she moves forward, is guided to the propeller in such a manner as to increase its efficiency and at the same time draw from the wake and turn to useful account, energy which would otherwise pass astern and be wasted. The contrapropeller has been fitted on 150 foreign (mostly German) and 12 American vessels and a saving of from 10 to 15 per cent. in effective horsepower for a given speed is reported to result from its use. As it can be fitted easily on vessels in service as well as on new ships and is comparatively inexpensive, it is likely to be extensively used, particularly on ships of moderate speed and power.

Bracketless Construction. — The most notable development in hull construction during the past year has been, without doubt, the invention, by Sir Joseph Isherwood, of the "bracketless" system of hull construction for tank steamers. The Isherwood system of longitudinal framing has been in use for many years, and, so far as tank steamers are concerned, has become practically universal. In the past, large brackets have been considered as essential in these vessels to connect the longitudinal hull framing with the stiffeners on the bulkheads forming the several oil carrying tanks or compartments. These brackets are present in large numbers (about 2,500 in a tank steamer of 10,000 tons deadweight capacity), are very heavy, costly to make and fit and rivet in place and a bother to keep oiltight where attached to the bulkheads. By a slight change in arrangement and increase in weight and strength of the general hull framing, it is proposed to do away entirely with the brackets, a much simpler and cheaper hull being the result. The first vessel to be built under this system is now in course of construction and, if the results anticipated are obtained, and there seems to be little doubt that they will be, it is a matter of great importance to the builders and owners of this very large class of commercial vessels. While not an American invention, the bracketless system is of particular interest to the shipping interests of this country, as the American fleet is by far the largest fleet of oil carrying vessels in the world.

Channel System.—Another development in hull construction, of much more restricted use, but still of importance as applicable to the construction of certain large fleets of small vessels—harbor barges, to be specific—is the Ellis Channel System of hull construction, in which the ordinary plated sides, bottom and decks of a "box" barge are replaced by structural channels, riveted flange to flange. Several barges of this description are already in service in New York harbor and should they prove as serviceable as hoped for and if they can be profitably produced at the very low price which characterized those now in use, a considerable activity in their production may be looked for.

Outlook.—The past few months have brought unmistakable signs of a revival of shipbuilding in this country. A considerable amount of new tonnage is under contract or actually in course of construction. Included in this are the two largest commercial vessels ever undertaken on this side of the Atlantic; passenger liners of the very highest type. A very large motor tanker, possibly the largest vessel of this type in the world, was contracted for in the last month of the past year and a number of other vessels are being considered and will, in all probability be contracted for in the near future. While new naval work has been practically at a standstill, two 10,000-ton cruisers, of very high speed are shortly to be laid down, one in a navy yard and the other by a private firm. The machinery for both of these ships, representing a total of about 200,000 shaft horsepower is to be built by contract.

Altogether the outlook for American shipbuilding and marine engineering was far more hopeful in the latter part of 1925 than it was in the opening months of the year.

MATERIALS OF ENGINEERING AND CONSTRUCTION

By C. Laurence Warwick

Secretary, American Society for Testing Materials

The six years that have elapsed since the *American Year Book* was last published have witnessed two outstanding developments in the field of engineering materials, namely, the rapid growth of standardization and greatly increased interest in research. The importance of standard specifications and tests for materials in relation to future industrial development can hardly be overestimated and is resulting in the constant extension of standardization into new fields. The importance of research in materials has been somewhat slower of realization. However, the industries are coming to appreciate their dependence upon research for the development of new materials and for extending and amplifying our knowledge of present materials. Moreover, standardization itself is ultimately a stimulus to research; for the suitability of materials for given services cannot always be measured by present-day standards, so that intensive study of materials and their properties is practically an economic necessity. Indeed, in some fields engineering practice has outstripped knowledge of materials, and here we see the more intensive research at the present time.

Fatigue of Metals.—Much has been learned in the past five years respecting the strength of metals under repeated stress and the phenomena of "fatigue" failures—a subject of growing importance in the design and operation of a large variety of machinery and structures subjected to repeated stresses. It is now known that fatigue is not due to "crystallization" of the metal as was once thought, but is really a progressive fracture that starts at some point of high localized stress and proceeds by spreading of minute cracks, which may be due to slip along cleavage planes in the crystals of the metal. Failure usually occurs suddenly and without appreciable plastic deformation.

It has been well established that wrought ferrous metals have an endurance limit, defined as a unit stress below which the metal is capable of withstanding an indefinitely large number of stress reversals; that this endurance limit seems to be more consistently related to tensile strength than to elastic limit; and that the ratio of endurance limit to tensile strength (the so-called "endurance ratio") for a number of steels of various compositions and heat treatments ranges from 0.45 to 0.55. The endurance limit of many steels is raised by suitable heat treatment, though not necessarily in the same ratio that static elastic strength is increased by such treatment. It seems to have been well established that if metal is repeatedly stressed below its original endurance limit the effect is to raise both the static and endurance strengths.

The existence of an endurance limit for the non-ferrous metals and alloys is not so well established. The brass and bronze compositions so far investigated seem to have an endurance limit; but it is not yet definite that such alloys as duralumin and monel metal have an endurance limit and further tests are necessary. The endurance ratio for non-ferrous metals is distinctly lower than for ferrous metals, ranging from 0.25 to 0.45 and varying widely for different metals and for different conditions of the metal.

Studies are now being made of the fatigue strength of metals at high temperatures. H. F. Moore and T. M. Jasper find that in most cases the endurance limit of normalized carbon steel, nickel and monel metal decreases slightly from ordinary temperatures up to 800° F. and falls off rapidly for temperatures above 900° F.; and that the endurance limit at any particular temperature approaches the tensile strength at that temperature as determined by prolonged tests (see under Properties of Metals at High Temperatures).

The endurance properties of metals have been determined for the most part by subjecting specimens to millions of cycles of alternate flexural, torsional or direct tensile and compressive stresses. The time consumed in such tests is very great, which lends much importance to the development of short-time tests. H. F. Moore reports that the endurance limit of many wrought ferrous metals may be reliably determined by observing the rise of temperature of specimens subjected to some hundreds of cycles of reversed stress; and D. J. McAdam has devised an accelerated torsion test in which the applied stress is automatically increased as the specimen "gives" under the originally applied stress. Important studies are also being made of the significance of the range of stress reversal with respect to the elastic strength of the metal.

Properties of Metals at High Temperatures.—A new importance has been given recently to the study of this subject by two significant industrial developments: the high temperatures (750° F.) and working pressures (600 lbs. per sq. in. and higher) now used in modern steam-power-plant operation; and the high temperatures, ranging from 750° to 1,000° F., developed in the "cracking" of crude oil. The metals at present commercially available for these services undergo considerable loss in strength at temperatures above 600° F. and metallurgists are not entirely agreed upon the details of their "strength-temperature" curves. Accordingly, two important problems are presented: first, the precise determination of the properties of metals at high temperatures; and second, the development of materials that exhibit improved properties, both as to mechanical strength and chemical stability, at these temperatures. As a first step towards the study of these problems, the American Society of Mechanical Engineers and American Society for Testing Materials have brought together in a Symposium on the Effect of Temperatures upon the Properties of Metals (Am. Soc. Testing Mats., *Proceedings*, vol. 2, *24*) a complete résumé of existing knowledge of the subject, including a comprehensive bibliography, and have sponsored an extensive investigation to standardize test methods, study the properties of metals at elevated temperatures and correlate tests in different laboratories with behavior as it appears in actual service.

Experimentation has brought out certain significant facts. Up to about 850° F. high strength of most steels is a function of composition and heat treatment, and steels having highest strength at ordinary temperatures show similar superiority throughout the entire range; from 850° to 1,100° F. the benefits to be derived from heat treatment are limited and strength is a function largely of composition. Above temperatures of 1,100° F. it is improbable that commercial steels can be produced to withstand continuously large loads, and we shall probably have to turn here to chrome-nickel, chrome-iron-nickel and similar alloys that show such great resistance to oxidation, corrosive agencies and high temperature and have been used for a number of years in many chemical and metallurgical processes.

Investigators are turning their attention to a study of flow in steel under long-sustained loads at various temperatures. H. J. French and W. A. Tucker (U. S. Bureau of Standards, *Technologic Paper No. 296*) describe three stages of flow of a low-carbon boiler steel, and find that the load that permits long life at 1,100° F. without flow, approximates the proportional limit at that temperature determined by the usual short-time test, a conclusion which has been confirmed by others. The correlation of long- and short-time tests at high temperatures is an important problem.

Corrosion.—Recent years have witnessed the inauguration, under the auspices of the National Research Council, of organized study of corrosion of metals. Technical literature is replete with valuable data. Much progress has been made in studying the theory and mechanism of corrosion and the electrochemical theory (W. D. Bancroft, "The Electrolytic Theory of Corrosion," *Journal of Physical Chemistry*, vol. 28) as amplified by recent investigations is generally accepted as explaining the fundamental phenomena of corrosion. The 1925 Corrosion Symposium of the American Chemical Society (*Industrial and Engineering Chemistry*, April, 1925) gives a balanced cross-section of present corrosion thought. The effects and relationship to each other of the numerous factors that influence corrosion are coming to be more clearly understood. These factors, it appears, have relatively a retarding or accelerating influence depending on surrounding conditions and the resultant of these contending forces determines the rate of corrosion in any particular case. Two interesting problems reported upon this year are the cause of pitting, now attributed to differences in oxygen supply rather than in the metal itself, and the formation of protective films which greatly retard the progress of corrosion. Microscopic study of corrosion holds many interesting possibilities.

An important line of attack of the corrosion problem is that of comparative corrosion tests. An outstanding example is the elaborate series of tests of uncoated steel and iron sheets exposed to three atmospheric conditions and totally immersed in four kinds of running water (Report of Committee on Corrosion of Iron and Steel, Am. Soc. Testing Mats., *Proceedings*, vol. 1, *20-25*). These tests, while not yet completed, have clearly indicated the superiority of copper-bearing metal in resisting atmospheric corrosion, although such material seems to show no superiority in the immersion tests. A similar series of exposure tests of various metallic-coated iron and steel products has been started this year (*ibid.*, vol. 1, *25*).

Accelerated corrosion tests are of great practical importance, for if properly related to the factors of ordinary corrosion they may give in a comparatively short time reliable indications of the rust-resisting properties of metals under conditions of actual service. A critical comparison and evaluation of four principal tests—total immersion, alternate immersion, spray and accelerated electrolytic—is being undertaken by the American Society for Testing Materials as a contribution to the organized study of corrosion (Report of Committee on Corrosion of Non-Ferrous Metals and Alloys, Am. Soc. Testing Mats., *Proceedings*, vol. 1, *24*).

Reference is made to a comprehensive tabulation of the properties of corrosion-resistant alloys—of which the iron-chromium alloys are the basic type—and some important contributions to knowledge in this field (Symposium on Corrosion-Resistant, Heat-Resistant and Electrical-Resistance Alloys, Am. Soc. Testing Mats., *Proceedings*, vol. 2, *24*).

Light Alloys.—Aluminum and magnesium and their high-strength "light alloys" with such hardening elements as copper, silicon, zinc and manganese, in both the cast and wrought state, are finding many engineering applications where light weight is an economic advantage or indeed an absolute essential, familiar illustrations being aircraft and automobile construction. Abroad, the magnesium-base alloys have been rather highly developed but in this country the greatest development has been with the aluminum-base alloys, of which the most prominent is duralumin, an alloy of aluminum with copper and magnesium. Duralumin, while having a tensile strength annealed of about 30,000 lbs. per sq. in. and after heat treatment and "aging" of about 60,000 lbs. per sq. in. with elongation of 20 per cent., is relatively difficult to fabricate; but a new alloy of aluminum and copper, containing slight percentages of silicon and iron, is described by R. S. Archer and Zay Jeffries (*Mining and Metallurgy*, February, 1925), which after suitable treatment has about the same strength as duralumin combined with improved working qualities. These experimenters also describe an aluminum-magnesium-silicon alloy that in the annealed state is quite soft, but which can by artificial aging be greatly hardened, having excellent machining and cold-forming properties. The development of the best properties of these alloys is dependent on thorough mechanical working.

S. Daniels and D. M. Warner (*ibid.*, July, 1925) describe an aluminum-copper-silicon alloy that may be sand cast and heat treated to give high strength, ductility, resistance to shock and good machineability. Other references are:

Streeter, R. L., and Faragher, P. V.—"Aluminum and Its Light Alloys," *Mechanical Engineering*, May, 1925.

Daniels, S.—"Magnesium and Its Alloys," *ibid.*, October, 1925.

Heat Treatment.—Heat treatment of metals, brought to a considerable degree of perfection with alloy steels, is now being applied to ordinary carbon steels, wrought iron and cast iron. R. H. Smith (Am. Soc. Steel Treating, *Transactions*, May, 1925) has shown that low-carbon steel may have its tensile strength increased from 50,000 to 125,000 lbs. per sq. in. by heating to high temperature and very rapidly quenching. The ability of wrought iron to resist shock is greatly increased by proper annealing. Pearlitic cast iron, formed by allowing molten iron to cool extremely slowly, gives a metal of fine microscopic structure, extremely adaptable for light and medium castings. It would seem also that the physical properties of ordinary cast iron can be materially modified by heat treatment (F. Grotts, *ibid.*, June, 1925). Recommended practices for various kinds of heat treatment are being formulated by the American Society for Steel Treating.

The science of metallography is an essential aid in studying effect of heat treatment upon the physical structure of metals. Standard methods of metallographic testing have been published (*1924 Book of A. S. T. M. Standards*), and magnifications of 5,000 diameters and higher are now possible. Metallographic testing is beginning to find a place in commercial specifications, recent specifications for condenser tubes containing a requirement for grain size.

X-ray metallography, a comparatively recent development, comprises two main divisions: X-ray crystallography, in which X-rays are used to study the crystal structure of metals; and metal radiography, in which internal defects in metal are shown by the X-ray. A recent report (Committee on Metallography, Am. Soc. Testing Mats., *Proceedings*, vol. 1, *25*) outlines the subject and gives an excellent bibliography. It is now possible, through studies at Watertown Arsenal and elsewhere, to make X-ray photographs through 3½ in. of metal and to detect a cavity 1/16 in. in diameter, and it is not improbable that improvements now being perfected may make examination of somewhat thicker sections a possibility. As a method of commercial inspection radiography is at present expensive, but the possibility of detecting dangerous flaws before parts are put into service is a decided advantage and the expense may be justified in the case of specially important installations. Thus, this method of examination has already been applied to certain important steel castings for the Weymouth Power Station of the Edison Electric Illuminating Company of Boston (*Mechanical Engineering*, May, 1925). The value of radiography as a means of controlling foundry practice is being recognized.

Cement.—Cement has become one of the most important materials of construction, yet our knowledge of its constitution and the processes by which it hardens is by no means complete. For the past decade efforts to improve concrete have been directed largely towards the study of aggregates, amount of water and influence of various admixtures (see under Concrete), and the belief is now growing that cement itself must be studied and further improved. Thus, the Portland Cement Association has established a fellowship at the U. S. Bureau of Standards for the purpose of making a fundamental study of Portland Cement and placing the art of making and using it on the highest possible scientific basis. The fellowship has completed about a year's work devoted to studies of the chemical systems involved and the hydration of cement in the presence of excess water.

Meanwhile, the American Standard Specifications and Tests for Portland Cement are widely accepted throughout the country as a basis of purchase. However, some difficulties are being experienced in securing concordant test results, for the testing of cement is not an exact science and the results are greatly influenced by seemingly minor variations in procedure. A Manual on Cement Testing has recently been issued (Am. Soc. Testing Mats., *Proceedings*, vol. 1, *25*) as an aid in the routine procedure of testing.

The requirements of cement for modern highway construction have been admirably discussed by A. T. Goldbeck (*ibid.*, vol. 2, *25*), who states that concrete for highway construction would be even more suitable from a technical standpoint than it is at present if it developed high tensile strength within a very few days with low shrinkage under action of moisture and temperature. Whether high-strength cement is the answer, as some highway engineers believe, has yet to be demonstrated from an economic point of view; although Goldbeck concludes that if cement of high early strength can be obtained with no decided increase in cost and no danger of disintegration, it is desirable and something towards which cement manufacturers should strive.

An interesting development in this direction is the production commercially of a high-alumina cement (similar to the French "ciment fondu") which in 48 hours has a compressive strength in 1: 3 mortar of about 6,000 lbs. per sq. in. compared to say 700 lbs. for Portland cement, and which in 1: 2: 3 concrete shows considerably higher transverse and compressive strengths at 24 hours than Portland-cement concrete at 28 days (H. S. Mattimore, *ibid.*). There has also been developed in England a modified Portland cement with slow initial set followed by rapid hardening, attaining in about three days the 28-day strength of normal cement (*Mechanical Engineering*, June, 1925).

Concrete and Reinforced Concrete. —The application to field practice of the principles of proportioning developed by laboratory experimentation is an outstanding feature of the Standard Specifications for Concrete and Reinforced Concrete prepared by a joint committee of five national organizations (Am. Soc. Testing Mats., *Proceedings*, vol. 1, *24*). These specifications represent the consensus of present opinion regarding materials, proportioning, construction and design of concrete and reinforced concrete structures, and they constitute an important step forward in the matter of "design" of concrete mixtures. In place of the common practice of specifying proportions of say 1: 2: 4, irrespective of nature and grading of aggregates, and using a fixed basic unit stress for concrete of perhaps 800 lbs. per sq. in. on the assumption of 2,000-lb. concrete, the specifications require that the engineer shall determine, by tests of available aggregate in advance of use, the proportions to produce concrete of the required strength; or, where this is impracticable, the engineer may use tables (based upon many thousand tests) giving proportions in which cement and a wide range of sizes of fine and coarse aggregates should be mixed to obtain concrete of given consistency and desired compressive strength. The basic working unit stress is then fixed at 40 per cent. of the compressive strength at 28 days, thus giving proper recognition to higher quality concrete. The specifications also require that the quantity of water used shall be the minimum necessary to produce concrete of suitable consistency for each particular use.

Field tests made under the auspices of the joint committee in connection with the construction of a large concrete building and a concrete bridge, and reported by W. A. Slater and S. Walker (Am. Soc. Civil Engrs., *Proceedings*, January, 1925) indicate that it is possible to meet the requirements of these specifications provided a tolerance is allowed which permits about 10 per cent. of the strengths to fall below 80 per cent. of the average strength. Examples are not lacking of successful construction under such methods. T. P. Watson (Am. Concrete Inst., *Proceedings*, vol. 21) describes the application of these principles to a reinforced concrete bridge at Pittsburgh and A. W. Munsell (*ibid.*) describes field control of concrete for the Delaware River Bridge at Philadelphia.

In an elaborate series of tests on the bond between steel and concrete reported by D. A. Abrams (Am. Soc. Testing Mats., *Proceedings*, vol. 2, *25*), the conclusion is drawn that the use of 4 per cent. of the 28-day compressive strength of concrete as a working unit stress in bond for plain bars, as allowed in the above-mentioned specifications, is justified in that it gives a factor of safety of at least 2½ against slip.

The "slump" test for consistency generally recommended as a control test for the important factor of water-cement ratio (see *American Year Book*, 1918, p. 609), does not seem to be so well adapted to dry mixes and a promising new test has been devised by F. H. Jackson and G. Werner (Am. Soc. Testing Mats., *Proceedings*, vol. 2, *25*). It consists in determining by weight the amount of concrete retained upon a 12-in. circular steel plate when a greater volume of concrete than could be retained upon the plate under any circumstances is dropped upon it from a given height. The wetter the concrete, of course, the less will be the amount retained. The consistency as thus determined is found to bear a concordant relation to the water-cement ratio and the method gives excellent promise as a control of concrete in highway construction.

The use of concrete in building units such as block, tile and brick is an important development and standards for such units are being studied most effectively by the American Concrete Institute (*ibid.*, vol. 21).

The influence of admixtures, such as calcium chloride as a hardener of concrete, and the effect upon concrete of acid and alkali-carrying waters are important subjects of study. These and others are discussed in the following references:

Abrams, D. A.—"Calcium Chloride as an Admixture in Concrete," Am. Soc. Testing Mats., *Proceedings*, vol. 2, *24*.

Gonnerman, H. F.—"Effect of Size and Shape of Test Specimen on Compressive Strength of Concrete," *ibid.*

Road Materials.—Highway engineers are supplementing their laboratory studies of road materials by the building of test roads for the purpose of observing under known and controlled traffic the behavior of various materials and types of road construction. Three such roads have been constructed by the state highway departments of California and Illinois and the U. S. Bureau of Public Roads. The latter, at Arlington, Va., is in the form of a circular track approximately 625 feet in circumference, and has been used to determine the resistance to wear of some sixty types of concrete pavements and the stability or resistance to "shoving" of about thirty bituminous paving mixtures. The concrete test sections were subjected to approximately 300,000 passages of a solid rubber-tire truck wheel loaded to 3,000 lbs., traveling at a speed of 22 miles per hour, as well as 50,000 passages of the same truck wheel with non-skid chains—equivalent to several years' traffic on the average concrete road. The results and conclusions from the test have been reported by F. H. Jackson and J. T. Pauls (Am. Soc. Testing Mats., *Proceedings*, vol. 2, *24*).

Because of the difficulties experienced in warm weather with the rutting and shoving of certain types of bituminous roads, the stability tests are of much importance. The results of the road tests are being compared with a newly developed laboratory test by means of which it is hoped to reproduce in terms of laboratory results the demonstrated relative stabilities of the road test mixtures. This test, as described by W. J. Emmons and B. A. Anderton (Am. Soc. Testing Mats., *Proceedings*, vol. 2, *25*) involves the molding under pressure of a small rectangular slab of the mixture and, by pressure exerted on one side of the confined specimen, extruding a portion through openings in the bottom and sides of the mold. A somewhat similar test has been devised by P. Hubbard and F. C. Field (*ibid.*), which measures the maximum load required to force a briquette of the bituminous mixture through a circular orifice in a mold. Both give promise of enabling the highway engineer to design bituminous paving mixtures that will have greatly increased stability and ultimately to evolve a theory of proportioning such mixtures.

The subject of sub-grade soils is now receiving the study that its importance in road construction deserves. Such factors as gradation, moisture content and adsorption of soils are being studied in the laboratory and by careful observation of actual field conditions. In fact, the whole subject of soil mechanics is a vital one to the highway engineer, particularly in its application to the sand-clay mixtures that are practically the only type of road economically possible for moderate traffic in many parts of the country. The subject has been discussed in a comprehensive way by C. Terzaghi (*Engineering News-Record,* Nov. 5, 1925, *et seq.*).

Paints.—Study of paint from the point of view of chemical composition is giving way to study of its physical characteristics, of which recent illustrations are stress-strain tests of actual paint films and accelerated aging tests in which ultra-violet radiation from artificial sources is utilized to simulate effect of sunlight. Such studies are yielding data that will have an important influence on paint technology. Elaborate investigations of varnish are being made, as well as of anti-fouling and anti-corrosive paints for ship bottoms (Report of Committee on Preservative Coatings, Am. Soc. Testing Mats., *Proceedings,* vol. 1, *25*).

A nitro-cellulose paint, pyroxylin enamel, has been developed that makes an excellent finish for automobile bodies, being highly resistant to light, heat and moisture. The basic material is cotton, specially purified and nitrated. After a process to prepare it for the admixture of solvents and gums, the resultant clear liquid is mixed with pigments to produce an opaque enamel that dries by evaporation (J. J. Riley, Soc. Automobile Engrs., *Journal,* September, 1925).

The U. S. Government has quite completely covered the field of paint specifications, including vehicles, pigments and mixed paints, and has recently issued a valuable report on the use of paints (U. S. Bureau of Standards, *Technologic Paper No. 274*).

Miscellaneous.—The comprehensive series of tests to determine the effect of sulphur in steel (see *American Year Book,* 1919, p. 605) is well along towards completion. The results of tests on rivet and structural steels with "residual" sulphur and on three grades of steel with "added" sulphur have been published (Am. Soc. Testing Mats., *Proceedings,* vol. 1, *22, 23, 24*). Tests on forging steels with residual sulphur are being made, with rail steels and castings next on the program. Formal conclusions have not yet been published.

P. D. Merica and R. G. Waltenberg (*Mining and Metallurgy,* January, 1925) have found that lack of malleability of ordinary cast nickel is due to the presence of sulphur in excess of 0.005 per cent., which forms an embrittling compound, Ni_3S_2. Malleability is completely restored by the addition of magnesium.

T. H. Wickenden and J. S. Vanick have described the properties of cast iron containing nickel in amounts up to 5 per cent. and chromium in amounts up to 0.50 per cent. (Am. Foundrymen's Assoc., *Proceedings,* 1925). It appears that cast iron can be hardened with nickel and yet be as readily machined as in the softer condition. Both nickel and chromium increase the strength of cast iron and nickel definitely improves its toughness.

Synthetic wrought iron of high grade is being manufactured by the Aston process (*Iron Age,* October 29, 1925). Molten iron is poured into a bath of slag and almost instantly solidifies into particles which settle to the bottom as a spongy, porous mass similar to a well-worked puddle ball. The process has the advantage of suitable control, flexibility and the prospect of alloy base metals and special types of slag not possible with usual puddling methods.

J. L. Schueler describes a new method of coating wire with zinc, termed "galvannealing" (Am. Electrochemical Soc., *Transactions,* 1925). In this process the wire, after leaving the molten zinc, is annealed instead of being wiped as in the ordinary hot-dip process. This heat treatment smooths the coating and makes it flexible and malleable. Test results so far seem to indicate the superiority of this heavy, uniformly applied, non-porous zinc coating.

American Standards for Softwood Lumber have been developed under the auspices of the U. S. Department of Commerce and Agriculture. Based upon tests of many species of wood by the U. S. Forest Service, they embody basic grades for yard and factory lumber and structural timbers and provide for a uniform lumber inspection service, which marks a forward step in the lumber industry. Standards for hardwood lumber are now being formulated.

We are coming to understand much better the physical properties of rubber that have led to its increased use as an engineering materials. The remarkably high resilience that makes it a good tire-tread material is leading to its use in other fields, such as lining of ball mills, of tanks and as a covering for wood and metal structures that are subjected to abrasion.

Physical testing of mechanical cotton fabrics such as tire fabrics, hose, belt and numbered ducks (see *American Year Book*, 1918, p. 614) has so well demonstrated its value that the principles and methods developed are being applied to other textiles used in engineering applications—and indeed to some textiles that are not strictly associated with engineering. Yarns and thread, cloth cement bags, asbestos textiles, rope and cordage, knit goods, woolens and rayon are among the materials now being tested in this way.

Gears and pinions, manufactured from cotton products bonded with phenolic synthetic resins under heat, give excellent wearing qualities with minimum noise and are finding important applications in industrial motors and the timing gears of automobiles.

Testing and Nomenclature.—Viewing the field of testing materials as a whole, one sees increasing evidence of the endeavor to develop tests that will more exactly define and determine those properties of a material that make it suitable for a given service. Some of our present-day routine acceptance tests determine, instead, certain properties that are possessed by materials found by experience to give good service. Such tests are of the "indirect" type, serving to control the uniformity of a satisfactory product; but it may not follow that materials not possessing those particular properties will not give good service. This is frequently brought out in applying new materials. Often it is difficult to devise a rational test for the intrinsic "suitability" of a material for given service and it is in such cases that actual performance tests are most valuable. This is well illustrated by the road tests and corresponding laboratory studies of bituminous paving materials already mentioned. Another illustration is that of mechanical rubber goods. The chemical and physical tests usually specified for such goods are often not a true index of the service life of the article, and investigators are therefore working on tests to measure such properties of rubber goods as the resistance to natural deterioration with age and to various kinds of abrasion.

Accelerated performance tests are a natural development of this type of testing, in which the several factors that bring about failure are intensified in order to hasten ultimate break-down. While the principal criterion of usefulness of the accelerated test is that it shall truly predict the behavior and life of materials under actual conditions of service, many of these tests are *per se* valuable tools in the hands of experienced investigators.

Testing of full-size structural members continues to contribute to our knowledge in important ways. Prominent examples this year are tests of built-up column sections of towers of the Delaware River Bridge and of concrete floor slabs of the bridge. Tests of strength and fire resistance of full-size walls, partitions and columns are bringing out valuable data that will influence specifications and tests for individual building units such as brick, tile and block.

The establishment of logical systems of nomenclature and the adoption of standard definitions of terms relating to engineering materials are receiving considerable attention in several of the national engineering societies.

Standardization.—There has been substantial progress this year in the promulgation of standards for materials. The American Society for Testing Materials has supplemented the 220 standards published in its 1924

Book of Standards with 36 additional standards covering copper trolley wire, condenser tubes, lime and gypsum, waterproofing materials and textiles; and has published 47 new tentative standards, including specifications for castings and bolting material for high temperature service, structural silicon steel, ferro-alloys, bronze trolley wire, bituminous roofing materials and paint pigments, and tests for petroleum products, road materials, electrical insulating materials and slate. Its standardization activities have this year been extended into the fields of electrical heating wire, slate, natural building stones and naval stores. The American Railway Association, Society of Automotive Engineers and American Concrete Institute have been active in materials standardization work within their respective fields.

The Federal Specifications Board is undertaking the unification of the purchase specifications of the various departments of the government, seeking at the same time to bring them where possible into accord with generally accepted commercial practice so that the field of supply for government purchases may be widened. The Board has issued about 350 specifications, many of which cover engineering materials.

The Division of Simplified Practice of the U. S. Department of Commerce is effectively giving expression to the efforts of a number of industries to reduce to an economic minimum the sizes, shapes and varieties of various manufactured products. About thirty-five simplified practice recommendations have been formulated, including some applying to such engineering materials as paving brick, concrete reinforcement bars, hollow building tile and paving asphalts.

The Department of Commerce has just issued a National Directory of Commodity Specifications, which contains a classified list of 27,000 specifications for about 6,500 commodities, indicating which ones are in general use, by whom they were prepared and where copies may be obtained.

The American Engineering Standards Committee, sponsored by the leading national technical societies and the several departments of the government, is functioning as an agency for coöperative work in the formulation of engineering standards, seeking to avoid duplication of standardization work and promulgation of conflicting standards. It is, essentially, the national clearing house for industrial standardization, placing this work upon a broad national basis and greatly facilitating the adoption of truly national standards.

The standardization movement has gained the attention of industry as a whole and the active support of many of its important groups. The objection to standardization on the ground that it weakens the incentive to invent and to develop new materials and new processes, is giving way to the realization that standards are simply an expression of the results of experience in the successful use of commodities and that they really conserve our time and energy for the pursuit of that fundamental research upon which the ultimate progress of our civilization depends.

INDUSTRIAL STANDARDIZATION

By P. G. Agnew

Secretary, American Engineering Standards Committee

Rapid Development. — Industrial standardization has developed with rapidity in the last few years; since it is now for the first time treated in the *American Year Book*, it seems fitting there should be included a brief outline of the general movement.

Significance. — By standardization is meant the concentration upon specific products and materials, both in production and in use, to the end of bringing about the greatest possible industrial efficiency. Through standardization yearly savings almost incredible in magnitude can be made. Actual savings now being made in the automobile industry due to organized standardization activities are estimated by the industry itself at 750 million dollars per annum.

Industrial standardization involves: nomenclature, including definitions of technical terms used in specifications and contracts; specifications for use as a basis of purchase, for example, specifications for paint, cement, metals; methods of testing apparatus and materials, particularly as a basis of acceptance; uniformity in dimensions necessary to secure interchangeability of supplies and the interworking of apparatus and parts, such as bolts, nuts, pipe, gears; provisions for safety; and concentration upon the optimum number of types, sizes and grades of manufactured products.

Four Stages.—According to the scale upon which it is carried out, the process of standardization may be classified roughly into four stages, namely: by individual firms, by technical and trade associations, on a national scale, and on an international scale.

Standardization by individual firms is now well developed in all the principal industrial countries, and unquestionably it has been pushed furthest in the United States. Every industrial plant is now carrying on standardization of its own products and processes, and its competitive success largely depends upon the completeness with which it has studied and solved these problems. Standardization within the plant is an essential element in mass production, and mass production in turn has been the chief contribution of the United States to the development of industry.

Group standardization, by technical and trade associations, is largely a development of this century. In many cases standards so developed have come into such general use as to make them essentially national in character, but generally systematic coöperation and understandings with other interested groups is necessary to bring about full national recognition.

Standardization upon a national scale has become necessary because of the fact that the scope of most standardization projects affects not only one industry but several. Standardization cannot reach full effectiveness until it is treated as a national problem. There are now national standardizing bodies in nineteen countries, all but one of which have been organized since the war. The work of these national bodies is being woven intimately into the industrial fabric.

Until recently the movement has been largely centered in and carried on by the technical man. It is now becoming recognized that standardization is a managerial problem of the first rank in industrial production, distribution and utilization, and as such deserves the fullest industrial support. It is significant that the American Engineering Standards Committee early in the year organized an advisory committee of first-line executives, who are now giving time and assistance to the solving of national standardization problems.

Government Activities.—The Government's activities in standardization, which are very broad, are carried on from the point of view of the Government as a purchaser and as an aid to industry and the public.

The Federal Specifications Board, whose function is to unify the specifications of the various branches of the Federal Government and to bring them into harmony with the best commercial practice wherever conditions permit, has completed its fifth year. Up to the close of the year 1925, the Board had officially promulgated approximately 350 specifications, which have become mandatory upon the various Government departments.

The Bureau of Standards is a highly developed and efficient laboratory devoted primarily to research and the standardization of fundamentals.

The Division of Simplified Practice is undertaking to bring about a reduction in the number of sizes and styles of manufactured products by getting the various industries and users together in conference. The work of the Division is having a highly stimulating effect upon the whole industrial standardization movement. Since its organization in 1921, about 40 simplified practice recommendations have been carried through and accepted by industrial groups concerned. A dozen more simplified practice recommendations are awaiting final acceptance.

In August, 1925, there was published by the Department of Commerce a Directory of Specifications, which contains classified and alphabetical lists and brief descriptions of existing commodity specifications. The classification includes approximately 27,000 existing specifications covering 6,000 commodities, and it will be found very useful in connection with purchases. The astonishing multiplicity of specifications on the same subject, as evidenced in the Directory, has brought sharply forward the problem of unifying them into consistent groups. Such a unification is an industrial and economic problem of the first importance.

A wide range of standardization activities is also being carried on by the Department of Agriculture.

American Engineering Standards Committee.—Typical of the progress has been made in the standardization movement as a whole is the work of the American Engineering Standards Committee, in which over 250 trade and technical organizations are now coöperating through more than 1500 accredited representatives. This Committee is the agency through which industrial standardization in this country is passing from standardization by and within associations, societies and governmental agencies, to standardization on a national scale, and through its method and procedure the standardization work of the many bodies concerned is being broadened and unified into a system of national industrial standards.

The work on individual projects is carried on in joint technical committees, composed of accredited representatives of all interested groups—manufacturers, employers, distributors, technical bureaus of the Federal Government, et cetera. The representation is arranged through technical, trade and governmental bodies. In giving its approval to a standard the Committee considers particularly the adequacy of representation of the various interests on the technical committee, and the procedure which has been followed, in order to make sure that all organizations concerned have had an opportunity to participate in the work, and that the work has been carried out under a procedure that has been regular, open, and above board, and that the standard represents a real consensus on what is best in American engineering and industrial practice.

Scope of the Movement.—The scope of the national standardization movement, in which 250 national organizations are now participating, covers projects in the following fields: civil engineering and building trades, mechanical engineering, electrical engineering, automotive (automobile and aircraft), transportation, shipbuilding, ferrous metallurgy, non-ferrous metallurgy, the chemical, textile, mining and wood industries, and the paper and pulp industry.

Typical of the work accomplished in the field of mechanical engineering is the project on screw threads, a standard which touches practically every industry. The approval of the standard on screw threads for fire hose couplings constituted an important step in the prevention of conflagration through lack of interchangeability of fire fighting apparatus. Substantial progress has been made in the work on pipe flanges and fittings. The standard on gauges and systems of gauging, including the question of fits, was completed and ready for issue at the close of the year. New projects include those dealing with pins and washers, radio, manhole frames and covers, power piping, graphics and drawings.

A particularly important part of the work has been in the field of mining standardization, and at present work on no less than 16 mining projects is going forward. These include codes for rock dusting (which was completed at the close of the year), mine illumination, ventilation, the use of explosives in coal mines, and underground transportation.

The industrial safety program now

includes over 40 safety codes, of which 16 have been completed, and work on a dozen others is well advanced.

International Coöperation.—Standardization on an international scale is still in its infancy, yet through the coöperation of the various national standardizing bodies there has been real accomplishment in several subjects, the most notable of which is ball bearings. Over 50 of the more important sizes of ball bearings are now standard throughout the world and are, of course, completely interchangeable.

Of special interest in the field of international standardization is the First Pan American Conference on the Uniformity of Specifications, which was held in the first part of January, 1925, at Lima, Peru. At this Conference, an official one, resolutions were passed providing for starting standardization work in the various Pan American countries. It was decided to hold another such conference in the United States within two or three years.

In the latter part of October, 1925, there was held in Zurich, Switzerland, a conference of technical experts, representing nearly all of the European standardizing bodies. The following subjects were among those discussed: screw threads, widths across flats, shaft heights for electrical machinery, shaft ends, couplings, grinding wheels, and pipe.

In April, 1925, there was held at The Hague a meeting of the International Electrotechnical Commission, at which a considerable forward step was taken toward agreement on the rating of electrical machinery, a subject which has been before the Commission for nearly a score of years. Substantial progress was also made in a number of other subjects, such as nomenclature, transformer oils, and lamp bases and sockets. The next meeting of the Commission, according to present plans, will be held in New York in April, 1926.

In connection with this meeting of the International Electrotechnical Commission, there will also be held in New York a conference of the chairmen and secretaries of the national standardizing bodies, for which the American Engineering Standards Committee will be host.

ENGINEERING STATISTICS

By W. H. Rastall

Industrial Machinery Division, Department of Commerce

Machinery Data.—The machinery manufacturing industry of the United States, owing to the infinite variety in the type, value, and purpose of its products, does not lend itself readily to statistical presentation. There are but few classes of machinery which can be defined accurately, but, in presenting the following, reference is made to machinery as used in the factories, mines and construction enterprises of the country. An effort has been made to eliminate all reference to household equipment, electrical and agricultural machinery, locomotives, office equipment, and the like.

The only general survey made of the machinery industry as a whole is that given by the United States Census, the returns for which are shown in the following table:

Year	Establishments	Wage Earners	Primary Horsepower	In Thousands of Dollars			
				Wages	Cost of Materials	Value of Products	Value Added by Manufacture
1914	11,392	405,422	856,423	$274,432	$ 405,159	$ 978,064	$ 572,905
1919	12,483	666,979	1,428,393	856,442	1,317,008	3,200,184	1,883,176
1921	10,364	425,728	(1)	547,628	869,748	2,053,609	1,183,860
1923	9,849	587,161	1,611,884	834,536	1,200,612	3,009,516	1,808,907

[1] Not called for on schedule for 1921.

American Machinery Exports.—It will be noted that for 1923 the value of the products of this industry was in excess of three billion dollars, with the result that it is one of the most important in the country when considered as a whole, although it may be improper to consider the production of these various types of equipment as a single industry because of the diversity of products involved. On the other hand, the United States is distinguished abroad for the labor-saving and other machinery produced in this country, for the ingenuity of its designers, and for the superiority of the engineering represented by this equipment. American machinery is shipped in very large quantities all over the world. The total returns for 1925 are not yet available, but in 1924 these exports were in excess of $130,000,000.

England and Germany are usually considered the most serious competitors for equipment of this character, but both of the above countries absorb very large volumes of American mechanical equipment, shipments to Great Britain alone being in excess of $14,000,000 for the year 1924. Many American machinery manufacturers recognize the importance and value of this export business and devote very careful attention thereto, in some instances exporting well over 25 per cent. of their total production, although this export ratio is a factor which varies greatly according to the nature of the product and the circumstances of the industries it serves.

The following table shows the detailed production of different types of machinery for the years 1921 and 1923, and also the volume that was exported in each year. This will provide a statistical foundation from which the industry can be studied.

Type of Machinery	Production		Exportation	
	1921	1923	1921	1923
Dredging and Excavating	$ 17,848,733	$ 38,240,576	$ 2,280,591	$ 1,518,005
Oil Well Machinery	27,415,031	52,158,398	11,306,713	6,626,079
Mining	30,290,171	47,589,778	7,563,544	10,137,068
Air Compressors	15,728,629	27,762,309	3,905,684	2,627,546
Metal Working Machinery	81,222,649	189,239,938	19,635,821	13,104,586
Shoe Machinery	9,481,791	12,399,414	1,797,094	1,324,256
Flour and Grist Mill Machinery	8,663,327	9,083,777	1,612,066	1,155,485
Pumps and Pumping	69,255,176	92,814,688	11 966,469	7,462,116
Textile Machinery	115,166,967	127,406,348	19,928,353	9,043,677
Woodworking Machinery	25,681,963	49,544,019	3,544,128	1,754,333
Laundry Machinery	12,982,709	19,077,439	1,304,073	1,262,887
Paper and Pulp Mill	31,580,944	30,341,629	2,987,657	2,006,812
Concrete Mixers	8,665,611	14,462,712	581,861	567,635
Ice and Refrigerating	33,174,126	36,541,766	1,913,014	2,264,867
Road-making Machinery	17,858,209	27,514,113	989,557	921,392
Elevators and Elevating Machinery	61,376,779	106,493,782	1,979,504	2,428,000
Cotton Gins	2,721,290	7,175,031	118,463	315,878

Industry Returns to Normal.—As an industry, machinery manufacture is peculiarly susceptible to changes in economic conditions. Previous to 1918, this industry operated at its utmost capacity because of the exigencies of war, and the demand was continued for some little time after the Armistice because of the boom that prevailed at that time practically all over the world. However, about 1920 there was a very sharp reaction. It was found that practically every industry was equipped for production far beyond any normal demand. Manufacturers and dealers were carrying very heavy stocks of machinery on hand and, through the change from war to peace-time production, large volumes of machinery of endless variety were thrown on the second-hand market. It has required years to relieve this glutted condition in the markets for both new and second-hand machinery. However, 1925 may be considered the first year in which a normal situation has been reached, for in the interval since the Armistice many of the problems resulting from the war and the transition to peace-time manufacture had been solved, and for the first time the volume of business justified manufacturers in general in showing a renewed interest in mechanical equipment; in fact, industry during the year underwent something of a revolution.

Progress in Designing.—Competition has been exceedingly keen in most lines of manufacture and those responsible for production have come to realize more and more clearly that efficient production can only be secured through the use of up-to-date machinery, properly installed, and equipped with appropriate accessories. During recent years very great progress has been shown in the redesign of many types of machinery. For example, that for the woodworking industry has practically been completely revised during the past three years, changes being made in the direction of adopting direct-connected, electric-motor drives and the employment of ball and roller bearings, as it is found that in this way the machines can be made to give greater capacity, more rapid and more accurate production, vibration is eliminated, machinery can be placed to more advantage, the lighting of the workshops is improved, dust is decreased; in fact, from every angle better and more rapid production is secured under cirsumstances that are more healthful and more cleanly, and stimulate the morale of the personnel.

Expansion.—Manufacturers report that the machinery business for 1925 was well in excess of that for 1923 and 1924, and, in general, they look forward to 1926 with a feeling of optimism mingled with the restraint that is necessary to prevent the evils of boom inflation, but it is generally recognized that in practically all branches of the industry factory capacity is in excess of any normal demand, with the result that although the volume of business moving is large and satisfactory, prices are being kept down to low levels through keen competition. A great deal of progress is being made, however, in the direction of standardized manufacture, the elimination of excess variety, the increased attention given to research and improvements in design and engineering, to the more concentrated attention on careful business management on the part of manufacturers, and to improved ethics among them when in competition.

The United States owes a great deal to its machinery industry, as it is the instrument which makes possible the high standard of living, comfort, and wages, for which this country is distinguished, and the people of the United States can look with a great deal of assurance to the progress made by the machinery industry during recent years—a development that was well maintained during 1925.

DIVISION XXX
GEOLOGY, METEOROLOGY AND GEOGRAPHY

DYNAMICAL AND STRUCTURAL GEOLOGY

By Kirtley F. Mather
Professor at Harvard University

Earth Structure.—A critical analysis of the geological relations of earth-condensation and resulting acceleration in rotation of the earth, prepared by the late Joseph Barrell (Am. Journ. Sci., 5th ser., Vol. 10, pp. 408-432, 499-529) indicates that stresses in the earth's body due to changes of oblateness are wholly submerged beneath those due to change of volume. R. A. Daly (*Proc. Am. Phil. Soc.*, Vol. 64, pp. 283-307) emphasized the close relationship between mountain building and igneous action to a degree not possible before the hypothesis of continental displacement had been imagined by Taylor and Wegener. Daly describes the continents as sliding on a thick shell of hot, basaltic glass, rigid but weak, and explains the mountain chains as structures compressed on the downstream sides of gigantic landslides.

A factor not ordinarily considered by geologists is called to their attention by Warren J. Mead in "The Geologic Rôle of Dilatancy" (*Journ. Geol.*, Vol. 33, pp. 685-698). Dilatancy is the expansion of granular masses when deformed due to the rearrangement of the grains, and the term is expanded to include all volume increase due to deformation. Its consequences have far-reaching geologic significance. It is quite likely, for example, that the active thrust-faults in San Benito County, Cal., described by Paul F. Kerr and Hubert G. Schenck (*Bull. Geol. Soc. America*, Vol. 36, pp. 465-494) are developed in response to dilatancy involved in the differential movement of the earth-blocks separated by the San Andreas fault.

The relation of earth temperature to buried hills and anticlinal folds, as presented by W. T. Thom, Jr. (*Econ. Geol.*, Vol. 20, pp. 524-530) suggested a new application of geology to practical affairs as well as an interesting train of purely scientific inquiry. The abnormally high temperature gradients beneath the Salt Creek and other oil-bearing domes is attributed to the truncation of the folds by erosion so that relatively hot strata are now exposed near their tops. Sidney Powers also directed attention to the fertile field for research in structural geology, enriched by data pertaining to activities of the petroleum industry in the Mid-Continent region (*Bull. Geol. Soc. Am.*, Vol. 36, pp. 379-392).

Geologic Processes.—The causes of deposition of calcareous materials in sea water have long been of great interest. In a critical and experimental study of Drew's bacterial hypothesis of lime precipitation, Charles B. Lipman (*Carnegie Inst. Pub.*, No. 340, pp. 181-191) found no proof that deposition of lime is accomplished by bacteria under natural conditions. There are several interactions, physical, organic and atmospheric, constantly going on in the sea-water which determine large lime precipitation without introducing hypotheses such as Drew's.

A great flood of glacier-born waters, which during the ice age swept down the Snake and Columbia valleys and resulted in noteworthy erosion as well as deposition of gravel bars and the Portland delta, was described by J. Harlen Bretz (*Journ. Geol.*, Vol. 33, pp. 97-115, 236-259).

The close relationship between seismology and structural geology is illustrated by the study of clastic dikes in eastern Washington, made by Olaf P. Jenkins (*Am. Journ. Sci.*, 5th ser., Vol. 10, pp. 234-246), who "is inclined to believe" that the jagged, ramifying sand and dust dikes near Walla Walla are fillings of cracks resulting from earthquakes during or subsequent to the glacial period. Similarly, a study of the earth movements accompanying the Katmai eruption of 1912, made by Clarence N. Fenner (*Journ. Geol.*, Vol. 33, pp. 116-139, 193-223), indicates that the tectonic movements accompanying the eruption were not caused by the surficial faulting in the Valley of Ten Thousand Smokes, which he attributes to the intrusion of a sill-like body of not great thickness beneath its floor.

Isostacy.—F. A. Melton presented (*Am. Journ. Sci.*, 5th ser., Vol. 10, pp. 166-174) an interpretation of isostatic anomalies, which emphasizes anew the considerable strength of the earth's crust and suggests the possibility of deep-seated rather than merely surficial heterogeneity within the body of the earth.

Eastern Canada.—Discussion concerning the oldest known rocks of North America was rife at the annual meeting of the Geological Society of America, held at Ithaca during the last week of 1924. F. F. Grout (*Bull. Geol. Soc. Am.*, Vol. 36, pp. 351-364) presented data tending to show that the Coutchiching series in the Rainy Lake district was younger than the Keewatin series rather than older as A. C. Lawson had concluded several years ago. Later, George W. Bain described a thick mass of sediments in the Upper Harricana Basin, Quebec, which seem to be distinctly older than the Keewatin rocks. If so, these sediments of the "Okikeska series" are the oldest rocks now known on this continent.

Mississippi Valley.—Two of the great batholiths of Minnesota, the Vermilion and Giants Range granite masses, are described by Frank F. Grout and Ira S. Allison (*Journ. Geol.*, Vol. 33, pp. 467-508). In each, the differentiation of magmas produced a considerable variety of rocks.

The latest addition to the Geologic Atlas of the United States, under preparation by the U. S. Geological Survey, is Folio 219, descriptive of the Central Black Hills in South Dakota, by N. H. Darton and Sidney Paige. As customary in this excellent and valuable series, the geography, geology and mineral resources of the region are described in detail. Of general interest is the conclusion that the shapes of the Tertiary igneous masses have been greatly influenced by the structure of the rocks invaded by the Tertiary magmas.

Coastal Plain.—The contribution which the oil industry is making to detailed knowledge of geologic structure, especially in such areas as the Gulf Coastal Plain where the determination of structure solely from rock outcrops is extremely difficult if not impossible, is illustrated by a comparative study of well logs on the Mexia type of structure, made by Frederick H. Lahee (*Trans. Am. Inst. Min. and Metall. Engineers*, Vol. 71, pp. 1329-1350). The Mexia fault zone is 30 to 40 miles east of the Balcones fault zone, and the two bound a great graben which is broken by numerous minor faults and which extends for many miles across Limestone and Navarro counties, Texas.

Cordilleran Region.—Among the outposts of the Northern Rocky Mountains on the Great Plains in Central Montana are two small laccolithic masses, North and South Moccasin Mountains. The South Moccasin laccolith is described by Harold S. Palmer (*Am. Journ. Sci.*, 5th ser., Vol. 10, pp. 119-133). The Bearpaw Mountains, 60 miles farther north, are surrounded by a belt of faulted folds of rather unusual characteristics. Frank Reeves (*Am. Journ. Sci.*, 5th ser., Vol. 10, pp. 187-200) presents evidence that this folding and faulting is quite shallow; although the formations underlying the Upper Cretaceous strata were involved in the thrust, according to his interpretation, they responded without being folded or faulted in any manner that has found expression in the structure of the outcropping beds.

Describing the Wasatch Mountains, Hyrum Schneider (*Journ. Geol.*, Vol. 33, pp. 28-48) interprets the Wasatch Front as an initial fault-scarp modified by erosion, rather than a fault-line scarp, and affirms that some of the ranges in the northeastern part of the Great Basin are fault-blocks. In similar vein, George D. Louderback (*Bull. Dept. Geol. Sci., Univ. Calif.*, Vol. 15, pp. 1-44) concluded that the period of scarp production in the Great Basin, especially in the western portion near the Sierra Nevada, occurred during latest Tertiary or early Quarternary time. W. M. Davis has also considered the Basin Range problem (*Proc. Nat. Acad. Sci.*, Vol. 11, pp. 387-392) and corroborates these results.

Pacific Coast.—Richard N. Nelson described the geology of the hydrographic basin of the upper Santa Ynez River, Cal. (*Bull. Dept. Geol. Sci., Univ. Cal.*, Vol. 15, pp. 327-396). The region is in the Santa Ynez and San Rafael Mountains, and the report is an excellent study of an area, somewhat difficult of access, rugged, and of complicated geologic structure. The "structural dynamics of the Livermore region" is the title of a paper by Frederick P. Vickery (*Journ. Geol.*, Vol. 33, pp. 608-628) in which a portion of the California Coast Range, 40 miles southeast of San Francisco, is described.

Alaska.—Aniakchak Crater, discovered in 1922 on the Alaska Peninsula, 150 miles southwest of Mt. Katmai, was described by Walter R. Smith (*U. S. Geol. Survey Prof. Paper* 132-J) as a gigantic hole, averaging 6 miles in diameter, from which between 8 and 15 cubic miles of rock and lava is believed to have been exploded into the air. It is the largest known explosion crater in the world and the nearest counterpart to the craters of the moon. The annual volume descriptive of the mineral resources of Alaska (*U. S. Geol. Survey Bull.* No. 773) includes papers which discuss the geologic structure of various parts of that territory, written by J. B. Mertie, Jr., W. R. Smith and Kirtley F. Mather.

Naval Petroleum Reserve No. 4 occupies a vast and little known portion of the Arctic shore in the vicinity of Point Barrow. The third expedition of geologists of the U. S. Geol. Survey, dispatched to that area, spent the summer of 1925 there, and the report of the first expedition, led by Sidney Paige in 1923, was printed during the year (*U. S. Geol. Survey Bull.* 772). The low flat coastal plain is now known to be underlain by coal seams and to contain several seepages of oil, but its real value as a petroleum reserve seems still in doubt.

EARTHQUAKES AND VOLCANOES

BY KIRTLEY F. MATHER
PROFESSOR AT HARVARD UNIVERSITY

Perspective.—During 1925 a greater number of persons in the United States were startled by earthquakes than during any previous year in the history of this country. For the first time in several years earth tremors shook the congested districts of the Eastern States, occasioning a marked though probably temporary increase of the average man's interest in seismic phenomena. Disasters from earthquakes occurred at Santa Barbara, Cal., Talifu, China, and Osaka, Japan, but in the perspective of history the year was not especially unusual.

NEW ENGLAND-MARITIME CANADA

Eastern Massachusetts was slightly shaken by an earthquake at 8:07 a.m., January 7, which originated not far off Cape Ann. China and bric-a-brac were hurled to the floors in towns north of Boston, and the quake was felt as far south as Providence, Rhode Island.

A very strong earthquake at 9:20 p. m., Feb. 28, alarmed the inhabitants generally throughout eastern Canada and New England. Tremors were felt as far south as Virginia and as far west as the Mississippi, but damage was confined to a narrow belt along the St. Lawrence River. The epicenter was probably about half way between Murray Bay on the St. Lawrence and Chicoutimi on the Saguenay River, in an uninhabited portion of the Laurentian upland (Hodgson, *Bull. Seismological Soc. Am.*, Vol. 15, pp. 84-99). Buildings were badly damaged and many tombstones overthrown at St. Urbain, Rivière Ouelle, and elsewhere upon the alluvial land bordering the St. Lawrence below Quebec. In that city the harbor works on the deep soil and filled ground of the "lower town" were considerably damaged although the quake was not alarming to persons half a mile away on the crystalline rocks of the "upper town." Similar influence of terrane characterized the quake in Boston; panic was narrowly averted in theatres and hotels on the filled ground where formerly were the Back Bay swamps, although in other parts of the city persons were quite unaware of the quake. Estimating the real intensity of this earthquake from the area affected and the damage in towns scores of miles from the epicenter, it appears dynamically of the same order as the Charleston earthquake of 1886. Freedom from loss of life and the comparatively slight property damage were due to the location of the points of origin, beneath an uninhabited wilderness rather than beneath a populous city.

Aftershocks.—The tremors of the February 28 quake were numerous and continued over a period of many weeks. In the first week more than a hundred tremors were noted in Pointe-au-Pic; on March 3 and 21, temblors were widespread in the St. Lawrence Valley. A shock was felt at Kamouraśka and Murray Bay on April 10 and another near the Saguenay River on April 25. The Murray Bay district was again shaken during the night of May 29; none of these tremors did any damage.

Eastern Massachusetts.—This section experienced a slight quake at 2:58 a. m. on April 24, which was felt throughout the area surrounding New Bedford, Marion, Middleboro and Brockton. A fainter and more local tremor rattled dishes at Lynn, Swampscott, and Salem, Massachusetts, at 12:51 p. m., May 4, but was not recorded on the Harvard seismograph, although only a few miles away.

Canada.—Another sharp tremor was noted at Kamouraska, Quebec, at 9:20 p. m., July 26. On October 9 at 8:58 a. m. central and southern New Hampshire was shaken by a local quake of moderate intensity which centered near Lake Winnipesaukee. Windows were broken at Ossipee, and chimneys were cracked at Sandwich, N. H., and Cornish, Me. Seismographs in the eastern states and Canada recorded a moderately severe quake at 6:00 a. m., October 19, but it has not been possible to determine its point of origin from the records and no report of damage nor of sensible vibration has been received. The earthquake may possibly have originated in the region of the St. Lawrence River, but that is by no means certain.

Slight earthquakes, accompanied by rumblings, were reported in the vicinity of Middletown and Hartford in the Connecticut Valley during the evening of October 29, about 8:00 a. m. on Nov. 14, and at 1:20 a. m., Nov. 16.

CARIBBEAN REGION

A tremor severe enough "to crack a few buildings" was reported to have occurred in Kingston, Jamaica, at 12:20 p. m., April 13, and another quake "caused excitement" in the same city shortly before 1:00 a. m., June 15.

EASTERN INTERIOR

A slight tremor was reported in Syracuse, N. Y., during the afternoon of April 7. A considerable area in western Kentucky, southwestern Ohio, southern Indiana and Illinois was disturbed by three distinct tremors at 10:06, 10:14 and 10:30 p. m., April 26, by the most widespread quake which has occurred in the Ohio-Mississippi valley in many years. The heaviest shocks were reported from the vicinity of Louisville and Owensboro, Ky., and small articles were upset at places as far north as Springfield, Illinois. A local shock broke a few windows in Edwardsville, Illinois, during the night of July 14-15, and about 6:00 a. m., September 2, Evansville, Ind., and adjacent parts of Kentucky were shaken for the second time this year.

WESTERN INTERIOR

Montana. — Central and western Montana and adjacent portions of Idaho and Wyoming were considerably shaken by sharp quakes at 6:23, 7:05 and 8:40 p. m., June 27. Many persons in Billings, Butte, Anaconda, Great Falls, Missoula, Livingston and Helena were panic stricken, and property damage totaling about $500,000 was caused in and near the Gallatin Valley. A few individuals were injured, but no lives were lost. Passenger trains were hemmed in by landslides along the transcontinental lines, and railroad tunnels were temporarily blocked by rock falls. The most intense shock was felt as far north as Saskatoon and Calgary, Canada, and as far south as Thermopolis and Casper, Wyo.

Several aftershocks were recorded, one of which, at 2:20 a. m., June 29, was fairly sharp at Helena. Another on July 10, about 8:00 a. m., was reported generally throughout central Montana, and again on July 20 at 10:08 a. m. a distinct shock was felt at Helena. Livingston and Bozeman were slightly shaken at 7:50 p. m., August 12, and a faint temblor was reported from the vicinity of Three Forks at 8:45 a. m., August 29. Other tremors in this train of aftershocks were felt at Helena at 3:45 a. m., September 19, at 2:30 a. m., September 30, and early in the morning of October 6. A slight quake was felt at Great Falls on November 8, at 12:07 a. m., and another shock occurred southwest of Sheridan, Wyoming, at 6:45 p. m., November 17.

Southern Kansas, western Oklahoma and the panhandle of Texas experienced a tremor about 6:10 a. m., July 30. Although the shock was felt over a large area, no damage was caused.

PACIFIC COAST REGION

California and Alaska.—A slight quake was felt in Los Angeles and surrounding towns at 10:15 a. m., January 10; no damage was reported. A very slight tremor occurred at Millbrae, Cal., at 1:05 a. m. February 10. Southeastern Alaska was shaken at 1:55 p. m., February 23, by the heaviest tremors which have been felt in that section for many years. The epicenter seems to have been at a point on the coast about 75 miles north of Valdez. A few chimneys were wrecked in Seward, water pipes and telegraph cables were broken, and buildings were rocked by two tremors which together lasted a half minute or more. The Sierra Nevada, northwest of Lake Tahoe, was shaken by several tremors on March 30, between 9:47 p. m. and midnight. The first shock was most severe, but caused no damage. Slight damage was caused by a quake at Calexico, Cal., on April 15, when three shocks were felt between 7:30 and 8:20 a. m. Other quakes shook Ketchikan, Alaska, at 2:30 p. m., April 29, and Los Angeles at 1:25 a. m., May 1. A very feeble shock was reported at Santa Rosa, Cal., May 10, at 5:04

a. m., and Los Angeles was again disturbed by an earthquake shock on June 12, at 2:18 p. m.

Santa Barbara.—A moderately severe earthquake destroyed or damaged a number of poorly constructed buildings in Santa Barbara and startled southern California at 6:44 a. m., June 29. Because of the emptiness of the business district at that early hour, only 12 or 13 lives were lost. Switches were pulled and gas mains closed by the engineers on duty in the power house so that no fire added to the seismic destruction reported as more than seven million dollars. The quake seems to have been caused by a slight readjustment of the earth's crust along a fault at the foot of the Santa Ynez mountains. The area of destruction was limited to a few acres, and the tremor was startling over an area which is only about 60 miles long and 10 miles wide. Dynamically it was therefore trivial in comparison with the St. Lawrence quake of February 28, which presumably originated much farther below the surface of the earth than did the Santa Barbara shock. Aftershocks were numerous and continued for several days. The stronger ones were felt on July 3 at 8:38 a. m., July 5 at 4:35 a. m., during the forenoon of July 10, and at 1:00 a. m. on July 11.

Later Coast Tremors.—San Francisco and the area immediately south of that city were shaken at 11:25 a. m., July 19, but no damage resulted from that temblor. Santa Barbara and vicinity were again slightly disturbed at 1:50 a. m., July 30. Anaheim, Glendale and other towns in southern California felt a very slight tremor about 2:00 a. m. on August 8, and Ventura reported a similar quake about 10:45 a. m. on August 12. Another light quake was reported from Seattle on August 14, and on August 30 Calexico was again shaken at 5:05 p. m. Other slight tremors occurred in San Francisco and Oakland at 7:30 a. m., September 30, in Santa Barbara at 4:30 p. m. on October 3, at 1:30 p. m. on October 9 and at 1:45 and 5:30 a. m. on October 30, and in Pasadena at 1:15 a. m. on October 5.

CENTRAL AMERICA

A number of quakes were felt in Central Mexico during the latter half of March and the first two weeks of April. Large areas in the State of Durango were shaken on April 1; Chalcahuites is reported to have been partially destroyed, and considerable damage resulted in Canutilla and Zuchil. Accurate reports are wanting, but there seems to have been some loss of life. A moderately heavy shock damaged some buildings in Managua, the capital of Nicaragua, on October 4 about 10:00 p. m.

EARTHQUAKE HAZARD

Research. — The events narrated have drawn attention to the facts that earthquakes may occur anywhere; that greatly increased research in seismology and earthquake hazard is essential to the welfare of crowded cities, and that "earthquakes are dangerous chiefly because we do not take adequate precautions against their effects, whereas it is possible to insure ourselves against damage by proper studies of their geographic distribution, historical sequence, activities, and effects on buildings" and on men. Only one seismograph has been in operation in New England, largely because of the false sense of security engendered by many years of freedom from startling tremors. During December, another seismographic station was installed, so that now both Yale and Harvard are thus equipped, but many more instruments are needed throughout North America.

Government Observation.—On January 31, the President approved an act of Congress authorizing the Coast and Geodetic Survey to make investigations and reports in seismology, and that organization soon outlined a tentative program of instrumental observations which it is hoped may eventually lead to the accumulation of data adequate for making earthquake predictions. At present, although the expectancy of loss and damage from earthquakes may be calculated from the seismic history and geologic structure of a region, there is no scientific basis for earthquake prediction.

Building Laws.—The Seismological Society's Committee on Building for Safety has submitted to the council of the City of Palo Alto, Cal., a "draft of general provisions to be inserted in any building code to secure better construction against earthquakes." Following the Santa Barbara quake a general tightening of building regulations was noted throughout California where the codes had of late years been increasingly lax. Earthquake insurance was written in large amounts, both on the Pacific Coast and in New England and New York State.

The Engineering-Economics Foundation.—This Boston organization, a post-graduate institution devoted to the study of emergency, did a real service by concentrating its resources upon the study of earthquake hazard. Research, held rigorously to observed, recorded and tested fact, provided organized knowledge which was used in teaching groups of engineers, hospital executives, public officials, and insurance men modern methods of meeting emergency so that earthquake loss of life and property might be reduced to a minimum. Records of past earthquakes in the New England-Maritime Canada region were gathered, and knowledge of present conditions in cities, which greatly increase the hazard from even moderate earthquakes, was notably advanced.

VOLCANOES

Mt. Lassen, commonly described as the only active volcano in the United States, maintained its customary calm throughout the year. A detailed report of its volcanic activity, containing a full description of the explosive outbursts of 1914 and 1915, prepared by A. L. Day and E. T. Allen, was published by the Carnegie Institution of Washington. Certain of the volcanic vents in the Aleutian Range and on the Alaska Peninsula were reported to be belching forth unusually large clouds of vapor during the latter part of the summer, but no distinct eruption took place.

Ometepe and Madera, twin volcanoes on an island in Lake Nicaragua, burst into eruption early in August, and ashes thrown from the two peaks spread ruin to nearby plantations. Earthquakes felt in Managua on April 14 were probably due to the activity of these volcanoes.

ECONOMIC GEOLOGY

By W. Elmer Ekblaw

Managing Editor, "Economic Geography," Clark University

Investigations and Results.—The field of Economic Geology has been a particularly busy and profitable realm throughout the year 1925. In exploration, in the development of new deposits and new methods, in the increased production and utilization of the world's mineral supplies, the year has recorded continued progress.

Technical and scientific work of the finest kind has been prosecuted by the national and state surveys and bureaus; and private, corporate, and institutional research and investigation have gone on apace. The United States Geological Survey and the Bureau of Mines have published the results of work accomplished in previous years, and have kept their staffs busily engaged in the field, laboratory, and library. By executive order, the division of mineral resources of the Geological Survey was transferred on July 1, 1925, from the Department of the Interior to the Department of Commerce.

This year's Bulletins of the Survey are rich in their record of valuable scientific achievement; the Water Supply Papers have been numerous and increasingly valuable; and the maps issued have revealed increased efficiency in field work and cartographic technique. *Geologic Folio* 219 (Central Black Hills, S. Dakota), by N. H. Darton and Sidney Paige, is a most valuable contribution to the economic geology of the country. The

Bureau of Mines has likewise achieved continued valuable results in the investigations over which it has charge, and its publications are all worth study. The State Surveys and Bureaus have added much of interest regarding the geological resources of their own regions.

Conservation.—A growing sentiment in favor of wise and intelligent utilization as the soundest policy of conservation seems to be apparent in all fields of geologic industry. In the case of our fuels—petroleum, gas, and coal; of our minerals, both metallic and non-metallic; and of our water supplies, the policy seems tending toward their present use as extensively as the needs of our people demand, with an ever increased prevention of waste, instead of saving them for future conjectural needs.

This tendency was clearly indicated by the consensus of opinion expressed at the Williamstown Institute of Politics by the members of the Round Table, of which Dr. C. K. Leith of the University of Wisconsin, was leader, on "Mineral Resources as a Factor in World Affairs." Though decrying unnecessary waste in every form, Dr. Leith and his colleagues were rather well agreed that laws and restrictions enacted to retard or restrict production and utilization of mineral reserves in opposition to contemporaneous demand might not be wise or beneficial.

The Round Table also discussed the desirability of the "open door" among nations, in the development of their mineral wealth, to promote peace among their peoples. By such an open door policy the monopoly of essential minerals by some power fortunate in the possession of great or exclusive supplies would not work to the harm or suffering of less fortunate nations. The United States, possessing almost incredible reserves of many of the world's most essential minerals, is in a peculiarly fortunate position, but even so, lacks adequate supply of certain other minerals critical in, or necessary to, some of her greatest industries. The United States has never closed her doors to the development of her mineral wealth by foreign firms or capital; but she finds that many of the unexploited possible deposits of the world are now being indirectly or directly barred to her scientists and her capital.

Geophysics.—To an extent never before attained, the year 1925 has been distinguished by the employment of geophysical methods, and geophysical equipment of exquisite precision and delicate adjustment to the discovery of mineral deposits. The use of the "Eötvös" gravity torsion balance has led to the delimitation of new and unsuspected salt domes in the Gulf coastal country and possible new oil fields of great promise; its use is being extended to metallic lodes and veins. The Lundberg-Nathorst method for the location of ore bodies depends upon the electrical conductivity of mineral deposits and the study of equi-potential lines, while the Schlumberger process for the same purpose depends upon electrical currents generated by the ore bodies themselves. Taussig's refined application of electrical oscillations in a wireless aerial suspended from an airplane or airship to the discovery of buried water bodies, petroleum pools, and mineral deposits suggests possibilities almost beyond credence.

Economic Geology, published eight times a year, continues to be the only American magazine that covers the field comprehensively. During the year 1925 the series of articles appearing in the magazine have been characterized by their wealth and diversity of material and excellence of form of presentation. The Society of Economic Geologists has coördinated research work as never before.

Metallic Minerals.—One of the outstanding publications that has appeared this year in the field of metallic minerals is R. H. Rastall, *"The Geology of the Metalliferous Deposits"* (London, Cambridge Univ. Press). General principles are discussed in eleven chapters, while occurrences of metals are discussed in nine more. It is a valuable and comprehensive work.

The significance of the great iron-coal districts of the world has become increasingly evident in the world's work. The great centers of industry, grouped about the fortuitous proximity of coal and iron deposits in the Ruhr-Lorraine industrial center, in the great manufacturing conurbation axially disposed about the Pennines in England, and in the equally great region of industrial activity of northeastern North America centered upon Pittsburgh, dominate the affairs of the world and make the North Atlantic Basin the dominant realm of the world's trade and commerce. The Pacific is never likely to become a major theater of man's activity; the entire supply of coal and iron fronting upon its waters is only relatively small in comparison with the reserves tributary to the North Atlantic.

The great economic and political problems and policies arising from the Ruhr-Lorraine fields are well treated by Guy Greer, in *The Ruhr-Lorraine Industrial Problem* (N. Y., Macmillan).

Significant developments in the metal industry have been the rapid rise to dominance of the Katanga copper district of Africa; the growing relative scarcity of lead; and the rapid increase in the use of specialized alloys, necessitating increased exploitation of zinc, tin, aluminum, tungsten and other similar metals. The precious minerals are being eagerly sought, but no striking discoveries mark the year 1925. The literature of the precious metals has been enriched by the publication of Adolph Knopf's "Geology and Ore Deposits of the Rochester District, Nevada," as Bulletin 762 of the United States Geological Survey, and other similar bulletins.

Non-metallic Minerals.—The use of the non-metallic minerals has grown spectacularly in the past quarter of a century. The rapid industrialization of the civilized nations of the world and the elevated standards of living have caused a demand unprecedented in the world's history. Most sensational of all has been the almost incredible quantity of petroleum produced and consumed each year. One of the valuable publications of the year is "American Petroleum; Supply and Demand," a report to the American Petroleum Institute, prepared by some of the most capable and influential executives in the oil industry, and from the view-point of the oil men as authoritative as it can be made.

The American Association of Petroleum Geologists has issued the ninth volume of its Bulletins, a most valuable and comprehensive series of technical and scientific papers concerned with the occurrence and development of oil deposits, by some of the most competent men in the field of geology. The Association works under a most rigid code of ethics, and the reports and papers of its members may be accepted as authoritative and conclusive. *The Oil and Gas Journal*, a weekly magazine devoted exclusively to the petroleum and natural gas industry, covers the whole field of exploration, production, preparation, and marketing.

The coal industry continues to engage the attention of the country. The strike of anthracite workers and the increased dependence of the prosperity of the country upon a continuous supply of coal have focused the eyes of the whole people upon the industry. A number of important books on the subject have come from the press. "What the Coal Commission Found" by W. Davis, published by the Waverly Press of Baltimore, and "The Case of Bituminous Coal" by Walton H. Hamilton and Helen R. Wright, issued by the Institute of Economics, present in an illuminating way the confusion and lack of coordination in the production of this essential commodity with which our country has been so profusely endowed.

With ever increasing scarcity of lumber, the rapid laying of new roads and building of new structures, and the more intensive development of all our activities, building materials of mineral source—sand, gravel, clay, gypsum, stone, and rock—are being used in greater and greater quantities, with no diminution of demand in sight.

Water.—As population increases, water as a factor in the world's economy becomes increasingly important.

Throughout the United States its value is being enhanced, whether for domestic use, for irrigation, or for power. The control of water supply, the protection of wells from pollution and watersheds from deforestation and erosion, the carrying of impounded waters from pure sources by great aqueducts to the congested centers of industry, have become problems of every municipality. Professional Paper 135 of the United States Geological Survey, by F. W. Clarke, is a valuable compilation of analyses from several thousand sources of the potable waters of the country.

Problems of irrigation and drainage must be solved in many places, if by these means the area of land possible for food and crop production is to be extended. Not only by the use of surface waters, but perhaps even more generally by artesian waters, some of our arid empire may be reclaimed.

Power.—The question of power engrosses the best engineering thought of the day. Programs of "super-power," "giant power," and "internationalization of power" have been proposed. George Otis Smith, Director of the United States Geological Survey, writing in *Economic Geography* for July, 1925, in a brief but exceedingly significant article, "A World of Power," points out the power potentialities of the world, and summarizes by text and illuminating chart the situation to-day, and as it may be later. Who would guess that Africa possesses 42 per cent. of the potential water power of the world, or why?

The most magnificent compilation of papers on the power resources of the world is found in the five volumes of the "Transactions of the First World Power Conference," issued in 1925 as the joint report of the delegates from forty political divisions of the world, from every nation concerned in the world's industries. It presents for the first time in adequate treatment, the primary significance of the world's sources of energy, their distribution and their relation to man's progress.

MINERALOGY AND PETROGRAPHY

By Herbert P. Whitlock
American Museum of Natural History

Crystal Structure.—Since the publication ten years ago of the highly important work of W. H. and W. L. Bragg, on X-rays and crystal structure (*Year Book*), each year has shown an increased interest and activity on the part of mineralogists and crystallographers along this line of research. Such results have been achieved and such possibilities opened up that it may well be said that many of the problems of physical and chemical mineralogy which have hitherto appeared obscure have, in the light of recent investigation, seemed within sight of solution, if not actually solved.

During the past year the literature of this important branch of crystallography has been enriched by two notable books in addition to the many short papers contributed to scientific magazines and journals. Sir William Bragg has written a popular résumé of his course of lectures, which were delivered at the Royal Institution in 1923-24, and which now under the title of *Concerning the Nature of Things* (N. Y., Harper's, 1925), renders available to the American reader an admirable exposition of the scope and significance of crystal structure. The work of Dr. Frederick Rinne, of Leipsig University, which has been translated by Walter S. Stiles and published under the title of *Crystals and the Fine Structure of Matter* (N. Y., Dutton, 1925), constitutes a book both far-reaching and important. Both of these texts are featured by illustrations of great clearness and in the case of Sir William Bragg's work of highly original and novel presentation.

Suggested Reforms in Mineralogical Nomenclature.—The nomenclature of mineralogy has always suffered from the fact that it grew rather than was evolved. Whereas the pioneers in the organic sciences early recognized the necessity of adapting to them a Latin nomenclature, understandable by scholars of every country and capable of indefinite expansion, the early laborers in the field of mineralogy were content to take what terms already existed in their own respective languages for the mineral species then known, and upon them to graft a national nomenclature. In this way there has resulted a deplorable lack of uniformity with regard to mineral names, the same mineral species often having many synonyms in various languages. Recognizing this situation a Committee on Nomenclature and Classification of Minerals was in 1920 appointed by the Mineralogical Society of America, which committee has recently issued a report (*Amer. Min.* 1924, vol. 9, p. 61), recommending certain changes in the nomenclature of minerals, based primarily on priority and uniformity as affecting American usage.

Dr. L. J. Spencer, writing in the *Mineralogist Magazine* (*Miner. Mag.* 1925, 20, p. 353), has reviewed the situation with more breadth of vision and, as far as the representative of a single nation can, has treated the subject with fairness. A perusal of these two attempts, however, will, in the opinion of the writer, render obvious the fact that no revision of the nomenclature that will in any measure be of universal scope can be accomplished except by the joint work of representatives from several nations, a situation which Spencer tacitly admits when he suggests that his list of revisions might be adopted by common consent by the Mineralogical Societies of England, France, Germany and America.

New Minerals.—During the year 1925 a number of new mineral species have been added to list. An outcrop of phosphate-bearing rocks near Hegendorf in Bavaria have yielded three new phosphates: an apple-green, hydrated phosphate of iron, which has been named *lehnerite; wenzelite,* a hydrated iron-manganese-magnesium-phosphate of a pale rose-red color; and *baldaufite,* an iron-manganese-calcium-magnesium phosphate, occurring in flesh-red crystals and resembling wenzelite in general color. A new silicate of the brittle mica group, called *rossmatite,* was found near Prilep in western Macedonia. To a new titanate and silicate of iron and serium, found in minute grains, in the Province of Minas Geraes, Brazil, has been given the name *kalkowskyn.*

There has been added to the long list of unusual minerals from Franklin, New Jersey, a new hydrated arseno-silicate of manganese, occurring in light brown masses, and named *schallerite,* after Dr. W. T. Schaller, of Washington, D. C. From Crestmore, California, another locality noted for the abundance of its new and rare species, comes a new hydrous calcium silicate, named *foshagite,* after Dr. William F. Foshag, also of Washington.

The name *metavariscite* has been assigned to orthorhombic crystallized variscite, a hydrated aluminum phosphate from the Lucin locality in Utah. A new hydrous calcium silicate was found in the vicinity of Kimberley, South Africa. This has been named *afwillite* in honor of Mr. A. F. Williams, General Manager of the DeBeers Consolidated Mines.

TERRESTRIAL MAGNETISM

By Daniel L. Hazard

Assistant Chief, U. S. Division of Magnetism and Seismography

Magnetic Surveys.—The magnetic survey of the United States is carried on under the direction of the United States Coast and Geodetic Survey. The work of the year has been principally the reoccupation of repeat stations for the determination of the change of the earth's magnetism with time, in the Philippine Islands as well as in the continental part of the country. With these additional secular change data it will be possible to reduce the results of past observations to 1925 and construct new magnetic charts for that date. The magnetic observatories at Cheltenham, Md.; Tucson, Ariz.; Sitka, Alaska; and near Honolulu, Hawaii, have continued in operation. The one formerly at Vieques, P. R., was discontinued on November 1, 1924, but a new one to take its place, near San Juan, P. R., will be in operation before the end of 1925.

Much of the field work of the Department of Terrestrial Magnetism of the Carnegie Institution of Washington has also been devoted to the occupation of repeat stations, particularly in South America, Falkland Islands, West Coast of Africa and adjacent islands. Special observations of the diurnal variation at stations in southern South America have given some rather unexpected results. This Department has continued the operation of magnetic observatories at Watheroo, West Australia, and Huancayo, Peru, and has coöperated with New Zealand in the maintenance of the observatory at Apia, Samoa. The available funds of the Department were not sufficient to operate the ship *Carnegie;* but the need of secular change data over the ocean areas, as well as on land, is fully recognized and it is hoped that means will be found to put this specially equipped non-magnetic vessel in commission again in the near future. Canada has made a large number of determinations of the magnetic declination in connection with the survey of the public lands. It operates magnetic observatories at Toronto and at Meanook, Alberta. The latter has heretofore recorded only declination changes, but it is soon to be equipped with horizontal intensity and vertical intensity variometers also. In Europe a coöperative magnetic survey of the Baltic Sea and adjacent land areas has been in progress, re-surveys have been made of parts of France and Germany and plans have been made for a survey of Norway. Evidence of the reawakening of scientific activity in Russia is seen in the establishment of a meteorological and magnetical observatory at Tashkent and a geophysical observatory at Jakoutsk, Siberia, which will eventually include magnetic observations in its program. Even during the war and the subsequent revolutions, the work of the older Russian observatories appears to have been carried on, at least in part. A very important addition to the net of magnetic observatories is the one recently established by Denmark at Godhavn, Greenland. The magnetic observatory at Kew, England, after a notable existence of three-quarters of a century, has finally been discontinued because of electric car disturbance and replaced by a new one at Abinger. Amunden's ship *Maud* arrived at Nome, Alaska, on August 22, 1925, after three years in the Arctic, during which time a regular program of scientific work, including magnetic observations, was carried out.

Instruments.—The compensation of a horizontal intensity variometer for temperature by means of an auxiliary magnet has been worked out successfully by George Hartnell of the Coast and Geodetic Survey, in charge of the magnetic observatory at Cheltenham, Maryland. With both horizontal and vertical intensity variometers compensated for temperature, the construction of observatory buildings will be simplified, as a larger range of temperature in the magnetograph room will be allowable, and the work of reduction of the observations will be made easier. The Department of Terrestrial Magnetism of the Carnegie Institution of Washington has designed a compass variometer for the investigation of local magnetic disturbances, the detection of effects caused by hidden magnetic objects or materials and for registering magnetic intensity variations with high precision. In Japan the sine galvanometer, heretofore considered as an observatory instrument, has been used successfully in the measurement of horizontal intensity in the field.

Investigations. — Special observations were made at the time of the solar eclipse of January 24, 1925, at Greenport and Ithaca, N. Y., and Longs Corner, Ontario. Unfortunately there was considerable magnetic disturbance at the time, so that little additional information was obtained regarding the effect of an eclipse of the sun on the earth's magnetism. The Department of Terrestrial Magnetism of the Carnegie Institution of Washington, with the coöperation of the Geophysical Laboratory of the same institution, is studying the effect of pressure on the critical temperature of magnetization, working with pressures up to 2,000 atmospheres. The results thus far are not conclusive but indicate that there is no very great change in the critical temperature under pressure. It has also made a further study of magnetic storms which begin abruptly and found evidence that they do not begin all over the earth at the same instant, but that they occur first in low magnetic latitudes and progress toward the poles, possibly with a progression in longitude also. The detailed study of the area of remarkable local magnetic disturbance near Kursk, Russia, has been continued, with a large number of gravity, as well as magnetic, observations.

The annual meeting of the Section of Terrestrial Magnetism and Electricity of the American Geophysical Union was devoted to a symposium on the change of the earth's magnetism with change from lesser to greater altitudes.

METEOROLOGY AND CLIMATOLOGY

By Burton M. Varney

Weather Bureau, U. S. Department of Agriculture

General.—Continued international coöperation by this country in meteorological work is recorded in the discussion of the activities of the International Commission for the Investigation of the Upper Air (*Monthly Weather Review*, May), of the International Commission on Solar Radiation (*ibid.*, July), and of the Section of Meteorology of the American Geophysical Union (*Bulletin of the National Research Council*, vol. 10, no. 53, July).

Solar Radiation.—Weather Bureau records of total solar radiation intensity at the earth's surface find increasing applications; *e.g.*, heat energy measurements are now involved in determinations of variability of daylight by electric lighting companies. Researches by H. H. Kimball (*Mo. Wea. Rev.*, Oct., 1924) indicate that midday solar radiation is richer in luminous rays than radiation received either earlier or later, and that daylight intensities are measurable with an accuracy of ±5 per cent. by applying to radiation intensities, as measured by pyrheliometer, the illumination equivalents of a gram calorie per min. per cm.^{2} of radiation for various zenith distances of the sun. The well known increase in the proportion of long wave lengths of direct sunlight as compared with the short, upon decrease in apparent altitude of the sun, Kimball has shown to be reversed for total daylight (direct sunlight plus diffuse skylight—*ibid.*, March), the proportions of the blues and violets becoming slightly greater than that of the reds and yellows as the sun's altitude decreases. Total daylight is bluer in winter than in summer because in winter the dust particles and water droplets in the atmosphere are smaller and fewer, allowing better transmission, especially in the short wave lengths, of both direct sunlight and diffuse skylight. On the question of measurable day-to-day fluctuations in the "solar constant" (that is, of the intensity, expressed in appropriate thermal units, of the solar radiation as if measured just outside the earth's atmosphere with earth at mean solar distance), Abbot believes such fluctuations proved by his determinations based on bolometric measurements (Solar Variations and Forecasting, *Smithsonian Misc. Coll.*, 77, no. 5). Mathematical analyses of Abbot's latest published data by Marvin and Kimball (*Mo. Wea. Rev.*, July) and Clough (*ibid.*, Aug.) appear to prove that fluctuations of atmospheric transparency together with unavoidable errors in Abbot's highly refined measurements completely mask any possible short-period fluctuation in solar intensity. It is believed concerted international action to obtain at high-level stations pyrheliometric measurements of the highest possible accuracy would help to solve the important problem of solar variability. Such coöperation has been suggested to the commission on Solar Radiation of the International Meteorological Committee.

Aërology. — The use of airplanes for getting upper air observations was begun in April, the Weather Bureau and the Bureau of Aëronautics coöperating. Data for various levels up to some 3 km. on pressure, temperature, humidity, height and thickness of cloud layers, visibility, etc., are telephoned to the forecaster at the Weather Bureau upon the completion of each flight. V. E. Jakl analyzed (*ibid.*, March) the results of balloon flights undertaken by the late Dr. C. LeRoy Meisinger, who met a tragic death in the Spring of 1924 through the burning of his balloon. Jakl finds that the flights support conclusions from ordinary aërological observations to the effect that the making of daily free-air pressure maps, on the foundation laid by Meisinger's researches and balloon voyages is feasible and only awaits determination of truer normals for the free air than are now available. From a study of conditions in the free air leading to precipitation, Jakl (*ibid.*, Aug.) finds the view confirmed that whatever the season, rain-making processes ultimately bring about a stratification of the atmosphere, precipitation occurring only in those strata in which the fall of temperature with increase of altitude equals or exceeds the rate at which a body of air containing saturated water vapor would cool upon ascent. L. T. Samuels made an extensive study (*ibid.*, after Nov. 15) of kite and balloon observations over the United States to determine, for winter and summer, average conditions of all observed meteorological elements in four quadrants and the centre of well defined cyclones and anticyclones. Four among the many important conclusions reached are, that features differentiating cyclones from anticyclones in this country are most distinct below about 2 km.; that for corresponding sectors, season, and altitudes, the average wind velocities are greatest in cyclones; that the rate of increase of wind velocity with elevation in both cyclones and anticyclones decreases or even reverses itself beginning at some 500 m. above ground and extending to altitudes of 1,000 to 2,000 m. before resuming the increase with altitude aloft; and that the light winds characteristic of lower levels in the centre of anticyclones, normally give place to high winds aloft. W. C. Haines has developed a plotting board for compounding wind vector quantities, which gives highly accurate results and is rapidly operated (*ibid.*, Oct.).

Instruments.—The publication by R. N. Covert of "Meteorological Instruments and Apparatus Employed by the United States Weather Bureau" (*Jour. Optical Soc. of America and Rev. of Scientific Instruments*, 10, no. 3, March) presents an abundance of technical information in condensed form. S. P. Fergusson (*ibid.*, Jan.) discusses in detail the methods of measuring humidity. A rain-gage for direct measurement of precipitation, which may be constructed of standard commercial materials and parts has been devised (*Mo. Wea. Rev.*, Feb.). Apparatus for testing individually the cells used in aneroid barographs has been developed and constructed in the Weather Bureau laboratory. A new aneroid barometer of special form, and a new microbarograph, have been tested and found to possess features of merit, but to need further development. Plans are under way for obtaining snow-sampling tubes made of duralumin, valuable for its strength and lightness. These tubes are used in measuring the water equivalent of a snow cover for the purpose of forecasting prospective water supply. Several experimental thermo-electric pyrheliometers have been constructed with a view to obtaining larger current values and quicker response to sudden changes in solar radiation as received at the earth's surface. A more sensitive and enlarged solar-radiation register, for use in connection with the pyrheliometer, has been introduced.

Tornado Investigations.—A study of the frequency of occurrence of these storms within the United States, and of resulting loss of life and property, has been made by H. C. Hunter (*ibid.*, May). He discusses tornadoes from 1916 to 1923 inclusive, and summarizes previous tabulations. Seven hundred and fifty-four separate tornadoes are on record for the period. Annual occurrence ranged from 121 in 1917 to 65 in 1919. A tabular review of recorded tornadoes from 1889 to 1897 inclusive shows a total of 424, the worst year being 1893 with 83, the best 1889 with 21. The relative frequency indicated for the earlier period is doubtless deceptive, many storms going unreported because population, and hence opportunity for damage by tornado and for observing them, was smaller. For both periods together, there is record of the loss of 3,232 lives, attributable to 405 tornadoes out of the total 1,178. Aggregate property loss (both periods) is placed at $86,406,000, or an average of somewhat over $5,000,000 annually during seventeen years. And there were, between the periods, nineteen years for which there is no adequate record.

Tropical Cyclones.—C. F. Mitchell (*Mo. Wea. Rev.* Supplement No. 24) presents exhaustive data on the frequency, places of origin and movement of these storms for the West Indies. He finds that hurricanes never develop in the eastern two-thirds of the Caribbean Sea; they either come from far to the eastward, or originate in its western third. They normally recurve into the north and northeast at the first favorable opportunity offered by adjacent pressure distributions, irrespective of the time of year or longitude. In cases where their paths are erratic, the cause is found in the obstruction of the hurricane cyclone by moving anticyclones. S. S. Visher's monograph on tropical cyclones of the Pacific (*Bul. 20 of the Bishop Museum*, Honolulu) is a valuable assemblage of data and a most useful source book on the geographic aspects of storms of this type in the Pacific area.

Temperature Investigations.—Contributions have been made to the study of normal temperatures for the United States, of the frequency of occurrence of stated temperature changes, of temperature as an indicator of prospective rainfall, of methods for preventing occurrence of damaging temperatures in citrus orchards. Marvin and Day have prepared revised daily normals of temperature for 161 stations (*Mo. Wea. Rev.*, Supplement No. 25). For stations having forty years or more of record, the weekly averages of maximum and minimum temperature separately were subjected to a four-term Fourier analysis, on which was based the computation of fifty-two weekly normals. Between these were interpolated the intermediate daily values. The means between the two daily normals thus arrived at are believed to give a normal daily mean temperature of the highest precision. For stations with less than forty years, normal daily values of highest and lowest temperatures were got by drawing a smooth curve through fifty-two weekly averages. Smith and Stevens present (*Mo. Wea. Rev.*, July) a series of diagrams showing the probable frequency, by months, of given amounts of change between the 7 a. m. temperatures of successive days at Montgomery, Ala., the computation employing the Gram-Charlier frequency curve applied to 1,000 observations per month. C. D. Reed finds (*ibid.*, June) through correlation methods, that in Iowa, as June mean temperature goes, so goes the temperature of the next three months. And, eighty-three times out of a hundred, if the June temperature is above normal, July rainfall will be deficient, the rainfall deficit being about a third of an inch for each degree of temperature excess. This significance of June temperature holds with a probability of 70 per cent. or better, throughout a belt which includes Iowa, Illinois and Indiana and adjacent parts of the surrounding states. Results of field tests of certain extraordinary mechanisms devised for mixing the air in citrus orchards to prevent injury to the fruit by freezing, show that Mr. Barnum's famous dictum holds. F. D. Young finds (*ibid.*, August) that these machines are without exception failures, and confirms the view that the only sure means of obtaining complete protection is through orchard heaters, now developed to a state of high efficiency. W. J. Humphreys (*ibid.*, Dec., 1924) presents evidence from certain lakes in low latitudes, and in respect of the processes by which bodies of deep water are cooled, to show that the abysmal temperatures of a sea or lake are, when higher than that of maximum density, determined by, and substantially the same as, the annual minimum temperature of the coolest portion of its surface. Abysmal temperatures thus become indicators of the temperature factor in the climate of the recent past in the region, according as the bottom water is colder or warmer than the surface water at its coldest.

Forest and Agricultural Meteorology.—The effect of weather on forest-fire occurrence has received increasing intensive study. H. F. Gisborne (*ibid.*, Feb.), investigating relations between rainfall and the moisture in the top layer of duff (decaying leaves and twigs covering mineral soil on the forest floor) found that both daily and average inflammabilities vary markedly for different sites affected by the same weather. The weather factor alone, therefore, cannot be used as an index to fire danger. Diagnosis, by the duff hygrometer, of moisture conditions on individual forest sites now recognizes six degrees of inflammability, from none (wettest duff) to extreme (driest duff). Weather forecasts, applied to these inflammabilities on individual sites, give forecasts of the degree of fire danger for each site. At Priest River Experiment Station, Idaho, where the study was made, forecasts proved 82 per cent. dependable on dry sites, up to 88 per cent. on moist. Changes in other weather elements such as temperature or humidity while very important, never produce differences in inflammabilities sufficient to cause serious errors in forecasting fire danger as determined by dryness of fuels. J. A. Larsen (*ibid.*) finds from a study of the length of fire danger season at different elevations in Idaho, that this decreases with increase of elevation in belts corresponding to the forest zonation. For the lower western yellow pine forest (2,000-2,500 ft.) there is, in summers of subnormal rainfall, a possible season of 150 days, which decreases to 76 days for sub-alpine forests at 7,500 feet. In summers with normal rainfall the figures are 139 and 67 days, respectively. Time of beginning of fire season in Spring is normally much earlier at low elevations, because the increase of temperature, which largely controls the Spring drying of the forest floor, advances from low to high elevations. The end of the season is often simultaneous at all elevations on account of the advent of general winter rains or snows. In Washington and Oregon during the fire season of 1925, close coöperation between the Weather Bureau and forestry interests, through especially assigned officials, kept fire losses relatively low in spite of the hazard being one of the worst and longest continued in the history of Weather Bureau records in the region. A. J. Henry discusses at length "The Weather and Agriculture" in *United States Department of Agriculture Yearbook,* 1924 (issue 1925).

Business Meteorology.—In view of increase in rain-insurance business, the need for interpretation of local rainfall records is being more clearly recognized. Thus G. M. French for Los Angeles, W. F. Feldwisch for Springfield, Ill., and E. H. Loveridge for Honolulu (*ibid.*, December, 1924) have analyzed the distribution of rainfall through the day for each month, and presented their results in graphs and tables suitable to form the basis for computing insurance rates.

Climatology — Arctic. — Ward reviews (*Geog. Review*, July) an important monograph by Pollog on temperatures in the Arctic, which gives extensive bibliography, several pages of temperature data, and numerous illustrative temperature curves. *Tropical:* Visher (*ibid.*) discusses, with special reference to Australia and the

Pacific, rainfall conditions as handicaps to tropical development, from the point of view that yearly variability of rainfall leads to droughts and deluges, and the rate of rainfall often to excessive run-off, erosion and soil leaching, all of which necessitates nice adjustment of agricultural and other practice to rainfall conditions before the tropics can be successfully developed. *Medical:* Probably the paper of outstanding interest in this field to the layman is Dr. Rosenau's "The Seasonal Prevalence of Disease" (*Sci. Monthly*, February) in which a wide range of diseases is discussed in the light of their relation and lack of relation to climatic and weather conditions. In a group of papers on relations of the atmosphere to human comfort (*Mo. Wea. Rev.*, October) C. F. Brooks and E. C. Donnelly discuss empirical equations designed to indicate the cooling power of man under various weather conditions, and to provide a basis for classifying weather according to its effect on human comfort; Messrs. Howe, Nichols and Switzer discuss the distribution of weather types in Canada, the United States and Mexico.

The American Meteorological Society.—Membership in the Society shows a healthy growth. Officers for 1925 were: President, W. I. Milham; Vice-President, A. E. Douglass; Secretary, C. F. Brooks; Treasurer, W. R. Gregg. There have been four meetings during the year, those of January and May at Washington, D. C., that of August at Portland, Ore., and that of December at Kansas City, Mo., all except the May meeting being held with the American Association for the Advancement of Science. Announcement has been made that the first award of $100 from the Meisinger Aërological Research Fund, for an outstanding research in aërology by any one in the Americas, will be made at the winter meeting of the Society in December, 1926. The monthly Bulletin of the Society continues to thrive under the editorship of Dr. Brooks.

Bibliography.—The chief publication media in this country for meteorological and climatological papers, notes, abstracts, reviews, bibliographies, etc., indicating American and foreign progress in these fields, are: *Monthly Weather Review*, *Bulletin of the American Meteorological Society*, *Geographic Review*, and *Science*. Outstanding books of the year have been R. DeC. Ward's *The Climates of the United States*, lucidly written, excellently illustrated, abundantly supplied with bibliographic notes. C. F. Talman's *Our Weather; What Makes It and How to Watch It*, a splendid meteorology for lay readers; C. F. Brooks's *Why the Weather*, a series of stimulating popular notes on a wide range of topics. W. R. Gregg's *Aëronautical Meteorology*, bringing to practical aëronautics a much needed summary of recent aërological researches in their bearing on aviation problems.

PHYSICAL GEOGRAPHY OF AMERICAN LAND AREAS

By Wallace W. Atwood

President of Clark College and Clark University

Regional Geography.—Following a long period of concentration on the development of principles, the present tendency is a study of physical geography by applying the known principles to particular regions. As we look over the contributions to the science of physiography made during the past year it is conspicuously true that each writer who is active in the pursuit of field studies is concentrating on the study of a particular region. Some new principles may be evolved and some refinements to principles already well established may be made but the new and present phase of development in this science may be characterized as the regional phase, now that the major physiographic regions of each of the continents have been defined and published in map form. We await a thorough analysis of the physiographic history of many of those regions.

Relation to History.—Each problem in geography is in some way definitely related to a section of the earth's surface. No problem in human geography can be intelligently approached without a thorough appreciation of the physical landscape in which the human drama is being worked out. The development of regional geography is therefore a great step forward in the science of geography and in the contributions which that science is able to make to the related fields of study. The events of history have been influenced by their geographic settings. The location of towns, the growth of cities, the development of railroad routes and canals cannot be correctly interpreted without the background which is furnished by a knowledge of the physical landscape where human adjustments are being made.

Climate.—The climates of the world and the physical features of the landscape, including the soil mantle in the various physiographic units, are of prime significance in the understanding of many of the most vital problems now confronting the more crowded nations of the world. A knowledge of these physical factors is essential in guiding the settlement and utilization of the yet undeveloped parts of the world. Climate and relief will continue to be the chief factors limiting the utilization of the earth's surface. As more intensive utilization of the lands must come in many parts of the earth, the special significance of these factors and the limitations which they impose will be more and more clearly seen and appreciated.

Shore Line.—The most notable and easily the most significant and valuable contribution that has been made to the literature of physical geography during the past year is the report on the study of a shoreline made by Professor D. W. Johnson, *England-Acadian Shoreline* (N. Y., Wiley). This contribution is based on several seasons of field work during which the author has visited every section of the coast under consideration. In the Nova Scotia district, Johnson has found many of the major features definitely related to the fault lines in the geologic structure of that peninsula. Kennebec and Penobscot Bays, as well as Long Island Sound, appear to be directly related to these structural breaks in the region. The volume contains outline maps of the great nest of drumlins along the coast of Nova Scotia and those in Boston Harbor. He treats in detail the harbor at Marblehead and the tying of Marblehead Neck to the mainland at Lynn, and the tying of Nahant and Little Nahant with the mainland is made perfectly clear. The evolution of the Nantasket Beach is made especially clear with the help of maps. The evolution of the shorelines of Cape Cod is presented in detail. Martha's Vineyard and the curved spits or hooks and sand bars associated with Long Island and the entrance into New York Harbor, are here presented with notable clearness and accuracy.

Continental Glaciation.—Of great significance in accounting for the surface features due to continental glaciation is the recent study of Ernst Antevs, *Glacial Recession* (Canadian Geolog. Survey, Memoir No. 146). The geological evidence relating to the recession of the last ice-sheet from New England was studied by Antevs in 1921, and the results of the work were published by the American Geographical Society of New York in 1922. The present memoir is the result of an extension of these studies northward into Canada. The method of studying the ice-retreat is that of Baron Gerard de Greer of Stockholm. It is based on the annual layers of silt and clay deposited in lakes which bordered the ice-sheet during the period of retreat or melting back.

The work in New England showed that the recession of the ice-sheet from Hartford, Conn., to the region of St. Johnsbury, Vt., occupied a period of approximately 4,400 years. This period represents only a fraction of the time that has elapsed since the disappearance of the ice-sheet from New England. The relationship between the waning of the North American and European ice-sheets and the probable correlation of these events are briefly discussed. The view is advanced that the remarkable interruption in the retreat of the ice in the region between Lake Ontario and Mattawa river northeast of Georgian Bay, corresponds to the equally noteworthy interruption of the ice-recession in the Danish islands and southwestern Scantia. According to this view, the time that had elapsed since the ice retreated from the Mattawa region northeast of Georgian Bay is approximately 13,500 years.

Uplands.—Another study in regional physical geography is Frank J. Wright, *The Physiography of the Upper James River Basin in Virginia* (Virginia Geolog. Survey, *Bulletin* No. 11). The area includes the head waters of the James River of Virginia. Similar phenomena are observable in rolling upland country common in many parts of the Rocky Mountains. This is interpreted by recent students to be an old worn down plain developed by running water. The elevations which rise notably above this rolling surface are all recognized as monadnocks; they stand out conspicuously because of their superior resistance to agents of erosion. This question has been studied by Arthur Bevan in his article, *Rocky Mountain Peneplains Northeast of Yellowstone Park* (Journal of Geology, Aug.-Sept., 1925).

While engaged in the general geological survey of the section of the Alaska Peninsula northeast from Chignik Bay, the survey party came upon a most remarkable volcanic crater. It is nearly circular and has a maximum diameter of 6¾ miles. The lowest part of the crater floor is 1,100 feet above sea level and contains Surprise Lake, a body of water with an area of two square miles. The walls of the crater rise from 1,200 to 3,000 feet above the bottom of the crater. A beautifully symmetrical cinder cone, the summit of which is 2,200 feet above Surprise Lake, occupies the south-central area enclosed within the crater rim. This crater is described by Walter A. Smith with the title "Aniakchack Crater, Alaska Peninsula" in the U. S. Geological Survey, *Professional Paper*, No. 132-J.

Wall Maps.—A need has long been felt for a series upon which should be shown the major geographic regions of the world as defined on the basis of their relief features. To fill the gap Wallace W. Atwood has published during the year *The Physiographic Regions of the World* (Wall Maps with Manual, Chicago, Nystrom). The classification adopted is simple and universal in its application: 1. Lowlands and Interior Plains; 2. Uplands and Plateaus; 3. Old Worn-down Mountains; 4. Young Rugged Mountains. These four distinct types of relief form the basis for the sub-division of each of the continents into its primary physical regions. Each region forms a natural unit in the study of physical geography. Each large regional map is accompanied by a small inset map showing the relief features, another which carries the regional and seasonal distribution of rainfall and the prevailing coast winds, a third upon which the regional distribution of population is shown, and a fourth which is a land utilization map. A manual has been published to accompany these maps and the methods of solving geographic problems through comparative map studies has been clearly set forth.

OCEANOGRAPHY AND OCEAN EXPLORATION

By H. A. Marmer
U. S. Coast and Geodetic Survey

Meeting of Section of Oceanography.—In this country a number of organizations are engaged in various phases of oceanographic work. The Section of Oceanography of the American Geophysical Union, therefore, devoted the annual meeting on April 30 to a consideration of the status of American oceanography with a view to coördinating the oceanographic activities of the various organizations. Reports on the oceanographic work carried on by the Bureau of Fisheries, Smithsonian Institution, Scripps Institution, Navy Department, Carnegie Institution, and the Coast and Geodetic Survey were presented by accredited representatives. A resolution submitted by the Section and adopted by the American Geophysical Union endorsed the plan of a proposed U. S. Naval Expedition for research in oceanography.

Improved Instruments.—Of the improvements in methods and instruments used in oceanographic work, two deserve special mention. An improved form of depth-finding apparatus for sounding the ocean depths by acoustic methods—the so-called echo-sounding—was devised by Dr. H. C. Hayes of the Navy Department. The radio acoustic method of determining a ship's position in hydrographic work has in the past year been developed by the Coast and Geodetic Survey to give accurate determination of position to a distance of 200 miles from shore.

Scripps Institution of Oceanography.—During the past year the Scripps Institution for Biological Research of the University of California at La Jolla, California, was changed from a biological institution into an institution of oceanography, and its name changed to the Scripps Institution of Oceanography of the University of California. This gives the United States a research institution in oceanography that should do much to advance the science of oceanography. Four main divisions of oceanography are comprised in the Institution's work, namely, geological, physical, chemical, and geologic oceanography.

Sea Level.—The question of mean sea level has received considerable attention recently, studies showing that altogether apart from the rise and fall of the tide, the level of the sea varies not only from day to day but from month to month and from year to year. The daily and monthly variations are relatively localized in area, but the variation from year to year appears to be much the same over large areas. Along the Atlantic coast of North America there appear to be two prominent variations in sea level, one with a period of approximately four years and the other with a period of about nine years. The question of variation in sea level is especially important in geodesy, which makes use of mean sea level as its basic datum, and in the study of subsidence and emergence of coastal lands.

Amundsen-Ellsworth Polar Flight.—Under the leadership of Roald Amundsen this expedition planned to fly in two airplanes from Spitzbergen to the Pole, which was expected to be reached in seven flying hours, and if a landing could be made, to carry out observations there for 24 hours, and return to Spitzbergen. The two planes took off from Kings Bay, Spitzbergen, on May 21, and after eight hours flying half the gasolene had been used. A descent was made for bearings, which gave the position as latitude 87° 44′ N. and longitude 10° 21′ W. On landing the planes were locked in by masses of ice and it took the party more than three weeks to release one of the planes and prepare a runway. On June 25 the plane took the air and in 8½ hours reached North Cape on the northern extremity of North-East Land. During the flight northward and return, about 60,000 square miles of unexplored area was observed and at the point of descent, 160 miles from the pole, two soundings showed a depth of 2050 fathoms, which tends to confirm Nansen's idea of a deep polar basin. Three birds seen flying northwestward suggest the possibility of land lying in that direction.

Meteor Expedition.—In April the German Survey Ship *Meteor* left Wilhelmshaven for intensive oceanographic work in the South Atlantic and neighboring Antarctic, with a complement of experienced oceanographers aboard. The plans of the expedition call for detailed investigations in various fields of oceanography extending over a period of nearly two years. Oceanic circulation, both surface and subsurface, temperatures, densities, and gas content of the sea water, plankton, and geology of the ocean bottom are to constitute the principal studies. The vessel is fitted out with modern oceanographic apparatus, including several types of echo-sounding apparatus.

Discovery Expedition.—The South Atlantic and Antarctic will also constitute the field of work of the British Royal Research Ship *Discovery.* This vessel was built for Scott's first Antarctic expedition. After being thoroughly refitted she left England in July with a scientific staff for two years of oceanographic investigations. The principal object of the expedition is to obtain information bearing on the whaling industry, the cost of the expedition being met entirely from public revenues of the Falkland Island Dependencies, in which the whaling industry has recently made great strides. Oceanographic conditions in the waters frequented by southern whales are to be studied and intensive work is to be done on the whale feeding grounds. Echo-sounding apparatus is included in the equipment of the ship.

Maud Expedition.—After having spent three years in the Arctic Ocean, Amundsen's Polar expedition in the *Maud* returned to Seattle on October 5. The *Maud* froze in early in August, 1922, near Wrangell Island and drifted, frozen in, until August, 1924, when the New Siberian Islands were reached. Here she came free of the ice and turned eastward, spending the winter near the Medvezhi Islands. Under the scientific leadership of Dr. H. U. Sverdrup the expedition secured soundings and tidal observations, and a series of observations on tidal currents, temperatures, salinities, and gas content of the sea water, both surface and subsurface. The area covered by these oceanographic observations extends from Alaska to the New Siberian Islands. The tidal-current observations are especially valuable since they constitute the first systematic tidal current observations in the Arctic Ocean, and together with the tidal observations should help in throwing light on the question whether the vast unexplored area lying north of Alaska is part of the deep open basin of the Arctic Ocean, or whether it contains a large tract of land.

International Ice Patrol.—Beginning March 23 the U. S. Coast Guard resumed its annual patrol of the area of the North Atlantic most endangered by ice during the ice season. Two vessels, the *Modoc* and the *Tampa* alternated in cruising the ice region in the vicinity of the Grand Banks, the patrol ceasing on July 12. In connection with this patrol work considerable oceanographic work was carried out, consisting of soundings, currents, and salinities. In all 56 stations were occupied at which systematic observations from the surface to near the bottom were made. The electrical conductivity method of determining salinity was successfully used, and experiments were made on the locating of icebergs by means of echo-sounding apparatus.

CARTOGRAPHY

By W. L. G. Joerg

Editor, Research Series, American Geographical Society

The present report covers not only 1925 but also the years intervening since the last report (*A. Y. B.*, 1919), as this period has been characterized by unusually valuable American contributions to the subject.

International Map of the World.—After a practical suspension of its activities during the war the newly established Central Bureau in Southampton (*A. Y. B.*, 1914, p. 606) published in 1921 its first report on the progress of the map. Others followed in 1922 (index map only), 1923, and 1924. Since the last sheets noted (*A. Y. B.*, 1915, p. 607; 1916, p. 608) 32 sheets, exclusive of the map of Brazil, referred to below, have been published by various countries. These sheets cover: in Europe, northern and central Sweden, southern Britain and western France; in Asia, all of India south of 24° N. lat., the Malay Peninsula between 20° and 4° N. lat., the main island of Japan south of 36° N. lat.; in Africa, parts of Portuguese East Africa and the Belgian Congo, and a strip of the Sahara from the mouth of the Senegal to the bend of the Niger.

Map of Brazil in 1: 1,000,000.—Designated as part of the International Map although issued by a private organization is a notable map of Brazil in 50 sheets in 1: 1,000,000, published in the extraordinarily short space of two years by the Club de Engenharia of Rio de Janeiro and engraved by the firm of Dietrich Reimer, Berlin. Although the map conforms with the International Map in its most distinctive feature, the representation of relief in altitude tints, the contours that are obligatory in that series are not employed.

Map of Latin America in 1: 1,000,000.—Likewise of governmental scope is the important undertaking begun in 1921 by the American Geographical Society of New York of publishing a millionth map of Latin America. While not claiming to be a part of the International Map it conforms with and even goes beyond the regulations of that undertaking. Its great merit lies in the fact that it is a critical compilation of source material, much of it unpublished, including surveys by commercial corporations. A diagram on each sheet showing the degree of reliability of the sources used and an accompanying textual discussion of these sources are invaluable innovations. To date eight sheets have appeared. The areas shown are: a strip between 66° and 72° W. and 8° and 28° S.; western Ecuador; Lower California (relief in contours only, interval 100 meters). One sheet (South C-19) has been published both in the Club de Engenharia and the American Geographical Society series and affords a criterion of comparison between the two methods.

Fundamental Maps of the United States.—Two basic maps of the United States are A. K. Lobeck's block-diagram map in 1: 3,000,000, 1921, on which relief features are represented in perspective on a geometrical base in a manner to reveal their origin; and a vegetation map in 1: 8-000,000 by H. L. Shantz and Raphael Zon (*Atlas Amer. Agric.*, Part I, Section E, 1924). The former should be studied jointly with the relief map mentioned in *A. Y. B.*, 1918, p. 638, and Fenneman's map of the physiographic provinces (*Annals Assoc. Amer. Geogrs.*, Vol. 6, 1916). What with these maps and Jefferson's cities map (*A. Y. B.*, 1918, p. 639), a body of standard map material is being established for the study of the physical geography of the United States as a whole.

Agricultural Atlases and the Dot Method.—Of the fundamental *Atlas of American Agriculture* being published by the U. S. Department of Agriculture under the supervision of O. E. Baker five instalments have appeared: Precipitation and Humidity, Frost and the Growing Season, Natural Vegetation, Cotton, and Rural Population. In this as well as the notable *Geography of the World's Agriculture* by V. C. Finch and O. E. Baker (1917), the distribution and amount of products, crops, etc., are shown by means of dots, a method which admirably combines the numerical quality of statistics with the synoptical character of generalized maps. This device is one of the important American contributions to cartography. Abroad it is more or less paralleled by, and has stimulated, the work of Professor Sten de Geer of the University of Stockholm (*Population Atlas of Sweden*, 1919).

Geographical Maps by the U. S. Geological Survey.—A measure of great importance is the Temple Bill, which passed both houses of Congress on February 27, 1925, (68th Congr. *Public.* No. 498, HR 4522). It provides for the completion of the topographic map of the United States by 1945. Other than an increasing number of sheets of this routine but fundamental map, the U. S. Geological Survey has published a number of maps of general geographical interest: maps of Ohio, Kentucky, Arizona in 1: 500,000 with relief in shading by J. H. Renshawe and, on the same scale, contour maps (interval 100 meters) of Arizona and New Mexico by N. H. Darton and a geological map of New Mexico. The 1: 500,000 state base maps (*A. Y. B.*, 1915, p. 607) now cover all the states except California; reductions to 1: 1,000,000 are also available of many states. An important product of war-time investigation is the Survey's *World Atlas of Commercial Geology* (1921). Part I deals with mineral resources, Part II with water power.

Bathymetric Chart Based on Echo Soundings.—The far-reaching importance of the sonic depth finder perfected by Dr. C. W. Hayes, research physicist of the Navy, is illustrated by the map issued by the Hydrographic Office (*Chart* No. 5149) in 1: 850,000, showing the relief of the ocean bottom off the coast of California from San Francisco to San Diego up to a depth of 2000 fathoms. The sonic depth finder opens up a new era in deep-sea sounding and the interpretation of submarine structure.

Air Route Maps.—An important series of maps has just (1924) been published by the Air Service. They consist of strips about 80 miles wide on the scale of 1: 500,000 along the following routes: Boston-Washington, New York-Chicago-Omaha, Norfolk-Washington-Dayton-Champaign (Ill.), Cincinnati-Kansas City-San Antonio, Montgomery-New Orleans-El Paso-San Diego. They show relief in green and brown altitude tints, main roads in white, towns in red. Details of landing fields are shown on the margins. For some areas this map affords the first adequate representation of relief on the scale of a general map.

Educational Maps.—The post-war period has seen the development of an American school of wall-map production, emancipated from European engravers and publishers (for a discussion see *Geogr. Rev.*, July, 1924). The most distinctive series is a set of American history wall-maps by Professors A. B. Hart and H. E. Bolton (1918-21). Professor J. Paul Goode has brought out (1923) the first American school atlas engraved in the United States since the development of modern geography.

Post-War Atlases.—This period, with its international readjustments, has also stimulated the atlas field. New editions of the standard atlases have been published (see comparative review in *Geogr. Rev.*, Oct., 1923); *Stieler*, 10th ed., Gotha, 1925; *Andree* (see *A. Y. B.*, 1915, p. 608), 8th ed., Leipzig, 1922; *Atlas Universel*, 2nd ed., Paris, 1922; and in the *Times Atlas* (London, 1922) an atlas comparable to these Continental atlases has been created for English-speaking people. The *Times Atlas* is further distinguished by the fact that relief is shown in altitude tints. In addition to these customary general reference atlases, the period has developed a new type, atlases of economic geography. The two best of this class are by M. Baratta and L. Visintin, the *Grande Atlante Geografico* (2nd ed., Novara, 1925), and by George Philip and T. S. Sheldrake, *Chambers of Commerce Atlas* (London, 1925).

EXPLORATIONS IN THE AMERICAS

By Robert M. Brown

Professor of Geology and Geography, Rhode Island College of Education

---

MacMillan Arctic.—The outstanding American exploration from the standpoint of popular interest and also from the standpoint of achievement was the MacMillan Arctic Expedition. The expedition was particularly well equipped: airplanes to explore the Arctic areas, especially the stretch of unexplored region lying north of Alaska, radios by which contact with headquarters in Washington could be maintained, cameras for color photography of native life, birds and the Arctic flora, instruments for recording atmospheric and tidal phenomena, and equipment for preserving many natural history specimens.

The MacMillan party left Maine on two vessels, the *Peary* and the *Bowdoin* during the last week in June, 1925, and returned in October, making a record in time as well as in accomplishments.

Three Navy airplanes were carried by the party and it was the hope that some of the great area of unexplored territory lying between the 120th West and the 130th East meridians and north of the 70th parallel might be reduced in amount. A wedge of the map of the Arctic regions between the 60th West and the 90th West meridians culminating at the Pole observed by Peary; an extensive stretch north of Europe covered largely by Nansen but also penetrated by others; and Northern Greenland and Grant Land, make up the sum of the area marked "known" north of the 80th parallel. Within this circle at least 60 percent is unknown, and south of it is one-half as much more of unexplored area.

The planes were much restricted in the consummation of the plans because of unprecedented and persistent fogs, cold and snow. It was not possible to establish bases on the edge of the Polar sea from which to explore this million square miles of unknown area; on the contrary the planes were kept close to Etah, the headquarters of the Expedition. Flights of the airplanes were limited in time and distance. Even so, some 6,000 miles of distance were covered by the planes,—much of it a repetition,—and about 30,000 square miles of area is estimated to have been seen by the fliers which resulted in the discovery of an uncharted mountain range. In addition, a beginning was made in air-current knowledge.

That the expedition did not accomplish its entire program is not strange since an excessive amount was planned for it during the short stay in the Arctic. The failure of the airplanes to realize their hopes gave rise to the report of general failure and the abandonment of the project. In other lines than the air service, the program was amply executed and the results when the observations have been analyzed will be of great moment. The Expedition had this unique feature, namely: of being the first Polar Expedition in daily contact with the press. The value of the radio in explorations of this kind proves to be considerable from the point of view both of explorers and of the public.

Scientific Results. — The National Geographic Society, under which with the coöperation of the Navy the expedition was undertaken, sums up the scientific achievements which make a very considerable addition to the knowledge of Polar conditions. First, it mentions the observations of Dr. Koelz in collecting specimens, some of them rare and a few heretofore unknown, including several species of gulls, Arctic hawks, land animals and fish. Second, Mr. Francis, chief aërographer, collected meteorological data which will have immediate effect in the United States in aiding the forecasting of the weather. It is claimed that no such thorough study of Arctic air conditions relating to the ordinary storm development and especially to the currents of the upper air have before been undertaken. If the future exploration of the Polar Regions is to be largely by some form of air craft, as both this Expedition and the Amundsen trial seem to indicate, such records will be of invaluable service and their extension a demand in the near future. Third, Lieutenant Riggs of the United States Coast and Geodetic Survey conducted a series of observations of tides, currents, temperature and salinity of the ocean waters. These observations are less easily translatable into immediate benefits to mankind but their total adds to the knowledge of oceanic conditions.

Southwest.—No other American expedition gained widespread notice during the year. A number were quietly at work in various fields of the Americas, and among these were:

1. The excavations begun in 1920 at Pueblo Bonito in Chaco Canyon National Monument, New Mexico, under the auspices of the National Geographic Society were continued. Here a massive communal dwelling estimated to contain at one time about 1,200 persons has been uncovered and enough equipment found to partially reconstruct the life of the people that flourished here some 500 years before the discovery of America. The present year's accomplishments are the establishment of a definite pottery sequence for the period of Pueblo Bonito's history and the indications of a foundation series which remains yet to be excavated.

2. A similar piece of work to the above was the Heye Foundation's excavations of Pueblo Grande in the southwestern part of the United States which is claimed to be the oldest town in North America north of Mexico, having existed about 2,000 years ago. It is established that in that day, according to the results of the excavations, the ancestors of the modern Pueblo tribes knew the arts of building permanent dwellings, of weaving cloth, of making pottery, of improving agriculture, and of developing such other arts as years afterwards made the Pueblo the highest civilization in America.

3. Under the auspices of the American Museum of Natural History, New York, two similar types of work are in progress. Investigations were conducted at Globe and Superior, Arizona, and prehistoric dwellings of large size are reported to have been discovered. In another locality the work begun two years ago in the Canyon del Muerto has been continued and remains of a very early people, the Basket Makers, have been revealed.

4. The Captain Field Paleontological Expedition to Argentina returned to Chicago early in the year with three collections of fossils which are expected to exemplify the order of extinct mammals peculiar to South America.

OTHER EXPLORATIONS OF INTEREST TO AMERICANS

By Robert M. Brown

Professor of Geology and Geography, Rhode Island College of Education

Mongolia.—The Third Asiatic Expedition of the American Museum of Natural History under the leadership of Roy Chapman Andrews reached San Francisco early in November. The field of operation was the Gobi Desert in Mongolia with the adjacent foothill country bordering the southeastern base of the Altai mountains. The expedition traveled about 5,000 miles of which about 2,000 were in unexplored country. The chief objective was the search for records of early man. No actual proofs were available that any very early man ever roamed these regions but in the adjacent territories there have been found some evidences of early inhabitants. Complete returns of the success of the expedition are not yet available officially, but newspaper accounts agree that considerable history of the Stone Age was uncovered; crude stone implements found; much additional fossil remains of reptilian and mammalian life added to the collection; and some evidences of rare and unusually early mammalian life exposed. One account further adds that evidences of a great redwood forest that might have covered the entire area of Mongolia were unearthed. The officials of the American Museum of Natural History content themselves with the report that this season's fossil collections probably exceed in importance those of any other year. These expeditions into the interior of Asia in search of records of greatest antiquity are the prominent undertakings in paleontology during 1925.

Himalayas.—Another expedition of great popular interest is the James

Simpson-Roosevelts Field Museum Expedition to the Himalayan regions of southwestern Asia. The three principals, Theodore Roosevelt, Kermit Roosevelt, and George Cherrie, are expected to carry on the Roosevelt tradition of hunting big game; and largely in this fact lies the reason for the general interest in the project. The party entered the Himalayan region from Karachi in northwestern India early in May where a railroad bore them to Rawal Pindi, from whence they proceeded by motor to Srinagar, capital and center of the Vale of Kashmir. From this point the expedition sets out into the mountains.

The object of the expedition is to obtain as complete a collection of the animals and birds of the region as possible. Special stress has been laid on the ovis poli. This animal is believed to be the "Great Sheep" of Marco Polo's writings and no specimen is known to be in America. The animal is said to inhabit crags and glaciers considerably remote from human travel and appears to have been but sparingly seen. The list of other animals which will be the object of the search by the three hunters are strange of sound and to the bulk of mankind mythical. They are the markhor, various species of ibex, the goa, the scharpoo, the goitered gazelle, the Yarkand stag, the snow leopard, and the long-haired tiger.

Two of the principals, Kermit Roosevelt and George Cherrie, were members of Col. Theodore Roosevelt's River of Doubt expedition in Central Brazil. In addition, Kermit Roosevelt was with his father in Africa. The party has then considerable accumulated experience in this type of work.

Amundsen's Aërial Arctic. — A third expedition of 1925 of wide popular interest was Amundsen's flight towards the North Pole. Officially this was the Amundsen-Ellsworth Expedition and it was under the sponsorship of the Aëro Club of Norway. The expedition was equipped with two Durnier-Wahl all-metal hydroplanes fitted with skis to land on ice, and capable of carrying in addition to the equipment three men. The plan to use Spitzbergen as a base and to conduct trial flights were carried out. The distance from Spitzbergen to the Pole is 600 miles which should be accomplished in about seven hours. If the party reached the Pole, a twenty-four hour halt was a part of the program in order to make observations. If difficulty was encountered, the plan was to reach the Greenland coast where Amundsen had a cache at Fort Conger. If this flight proved successful, a second one across the Pole to Alaska was projected. The distance is 1800 miles or about 21 flying hours across the Pole from Spitzbergen to Alaska.

Favorable conditions for the flight were promised and on May 21, the planes left Spitzbergen; within an hour the expedition encountered fog but rose above it and in two hours the party were in clear weather again. After flying eight hours an open-water lead was seen and a descent was made in order to get bearings. One plane was immediately caught in an ice jam and the second plane was soon locked in the ice. This was in Latitude 87° 44′ North, about 160 miles from the Pole. It was estimated that 611 miles had been covered in the eight hours, or enough to have easily reached the Pole,—the extra distance of about 190 miles is accounted for by the headwinds which caused a drift of the planes. The labor of extricating one of the planes from the ice occupied the next three weeks while the world waited for news. After a number of failures, the party were able to clear a space on the floe large enough for a take off. On June 15, after a flight of nine hours, the party reached the northern end of Spitzbergen and two days later they were at King's Bay, the starting point. Apart from the experiments in the use of airplanes, Amundsen's task was a geographical exploration of the Norwegian section of the Arctic region. As in the case of the MacMillan flights unknown land areas were looked for but no indications were noted. On the contrary, excessive depths of the Polar ocean were recorded at the point of landing.

Difficulties.—It would appear that the problem of aërial navigation near the Pole is beset with certain mechanical difficulties; chief among them are the problems of steering a course and of finding geographic position. The use of the compass in high latitudes embodies a knowledge of location so that the correction (magnetic declination) may be made, and furthermore in positions so near the magnetic pole, the vertical component of the earth's magnetism is stronger than the horizontal. In order to overcome this difficulty both Amundsen and MacMillan used a solar compass. "This instrument, provided the flight is maintained on a given meridian, indicates to the navigator true north, for once the instrument is set a clockwork mechanism automatically corrects for the constant change in the sun's hour angle." The second problem of finding one's position has been partially solved by various instruments which give distance, direction, speed, and drift data so that a process similar to dead reckoning is used. The use of the sextant, the best known instrument for this purpose, is not adapted to the conditions offered in flying.

Arctic Future. — The problem of flights is at the dawn. The two Polar expeditions were unusually fortunate when it is remembered that Polar expeditions have only recently been launched without casualties and that flying under the best of conditions has not been long reasonably safe. Landings, especially forced landings, would apparently wreck any expedition if the ice conditions about the Pole are as bad as have been reported in all Polar trips, and landing in open lanes was in Amundsen's case close to tragic. The explorations from the air in the case of Dr. A. Hamilton Rice's Expedition in 1924 from Manaos up the Negro, Branco, Uraricuera and Parima rivers in Brazil demonstrated how much may be accomplished in comparison with the slower process of boats or animal power. It is confidently expected that successes similar to the Brazilian successes will attend polar flights in the immediate future.

DIVISION XXXI
CHEMISTRY AND PHYSICS

INORGANIC AND PHYSICAL CHEMISTRY

By Hugh S. Taylor
Professor at Princeton University

New Elements.—The number of elements which remain to be discovered has this year been still further reduced from four to two. Noddack and Tacke have announced to the German Chemical Society the discovery of Elements, Nos. 43 and 75 respectively, the eka-manganese elements of the seventh group of the periodic table. For these elements, the discoverers have suggested the names masurium and rhenium. They have been discovered, as was hafnium, by the X-ray method of analysis due to Moseley. The search was made among platinum ores and was successful in the mineral columbite. No data are yet available to indicate any actual separation of the elements, the identification being made from the position of the characteristic X-radiations of the elements in question.

Other Elements.—The new element, hafnium, has been the subject of intensive study both as to physical and chemical properties. It gives promise of commercial importance as a useful metal for filaments as a source of light or for thermionic emission. A wealth of patents have been filed on methods of separation, preparation and purification (e.g., Br. Pat. 219034; 219327). Thorium in a ductile form has been developed by the Westinghouse Electric Company's Research Laboratories; and tantalum in commercial quantities by the Pfannstiehl Company. A new process of chromium plating due to C. G. Fink has reached an important stage of commercial development. The same worker is responsible for an electrochemical process for the renovation of antique metal articles which are badly weathered.

Transmutation.—Efforts at transmutation of the elements have centered this year on the effort to obtain gold by electrical bombardment of mercury. The most positive results are given by Miethe (*Naturwissenschaften*, Vol. 12, pp. 597 and 1211), who obtained amounts, capable of being weighed and analyzed, from the residual mercury in a mercury vapor lamp after operation at high voltages. Other German scientists have announced negative results but Miethe in a recent lecture (*Deut. Chem. Ges.*, June, 1925), maintained his stand and gave the results of atomic weight determinations of the gold. Nagoaka (*Nature*, vol. 116, p. 95), similarly reports gold from mercury arcs struck under paraffin oil with a potential of 15×10^4 volts/cm. at the moment of discharge. In one set of experiments iron and mercury electrodes were used, in the other tungsten and mercury. The method of test for gold was the production of ruby glass.

Reactions of Inert Gases.—Numerous reports of combinations of mercury with helium have been made. Manley (*Nature*, vol. 114, p. 861, vol. 115, p. 337), reports a helide of the formula HgHe, stable below red heat formed by combination in the glow discharge. Boomer (*Nature*, vol. 115, p. 16) examined mixtures of helium with mercury, iodine, sulphur and phosphorus under electron bombardment, at surfaces cooled in liquid air. Evidence obtained points to the formation of solid compounds having vapor pressures of the order of 0.0005mm. Hg at —185° C. The compounds decompose on elevating the temperature. Joos (*Naturwissenschaften*, Vol. *13*, p. 697) suggests that mercury helide is formed from helium in the 2S and mercury in the $2p_3$ metastable states. He states that mercury-neon compounds are possible. The compounds are of the ozone type, a glow discharge being essential in the preparation.

Atomic Hydrogen. — Considerable attention has been devoted in the preceding year to the chemical properties of hydrogen in the atomic condition. Hydrogen atoms may be prepared by passing a high tension discharge through rarefied hydrogen molecules the atoms being drawn off from the middle of the discharge tube by a vacuum pump system (Wood, *Proc. Roy. Soc.*, 102A, 1). The atoms may also be produced by collision of excited mercury atoms with hydrogen molecules (Cario and Franck, *Z. Physik*, Vol. *11*, p. 162). It has been shown by Bonhoeffer (*Z. Physik. Chem.*, Vol. *113*, p. 199), that atoms produced by the first method readily react with sulphur, arsenic and phosphorus at room temperatures giving the corresponding hydrides. The atoms readily reduce metallic salts to the free metals, in contact with which, atomic hydrogen is catalytically converted to the molecular form. Marshall has shown (*Jour. Phys. Chem.*, Vol. *28*, p. 842), that the atoms also react at room temperature with unilluminated chlorine yielding hydrogen chloride, an observation of importance in the problem of the hydrogen-chlorine combination. Dickinson, using the Cario-Franck method of preparation, has shown (*Proc. Nat. Acad. Sci.*, Vol. *10*, p. 409) that the atoms combine at room temperatures with oxygen. Taylor and Marshall (*Jour. Phys. Chem.*, Vol. *29*, p. 1140), have shown that many hydrogenation processes may be achieved with the atoms so prepared. With unsaturated hydrocarbons, the atoms seem to yield the corresponding free radicals, for example, ethylene, the ethyl radical. Wood's method of preparation had indicated that collisions of hydrogen atoms only infrequently resulted in the production of molecules and that recombination was in the main secured at contact surfaces. Bonhoeffer's data confirm this.

Atomic Bromine.—A similar observation has now been made with respect to the recombination of bromine atoms. From photochemical studies of the hydrogen-bromine combination and of the thermal reaction in presence of iodine as an inhibitor Bodenstein and his co-workers (*Z. Elektrochem.*, Vol. *30*, p. 416; Z. *Physik. Chem.*, Vol. *114*, p. 208), have shown that only about one collision in every thousand between bromine atoms results in molecular combination. This efficiency is materially higher than the collision efficiency in molecular processes where, for example, with hydrogen iodide at 556° Abs., the efficiency is 1 in about 10^{18} collisions. Nevertheless, the atomic efficiency is less than recent theories have assumed. It was formerly believed that every such atomic collision would be fruitful in the production of molecules.

Molecular Bromine.—This grows scarce owing to its extended use in the organic chemical industry and especially in the preparations of lead tetra-ethyl, the antiknock for motor fuel. A method of extraction from sea water has been developed by the DuPont Company according to C. M. Stine (A. C. S. meeting, Los Angeles, 1925). The bromide in sea water is treated with chlorine and the resulting bromine converted to insoluble tribrom-aniline, which is then recovered in filter presses. The experiments conducted at sea, in the Gulf Stream, demonstrated the practicability of the process at prevailing prices.

Bromination.—An important study of the effect of substitution on the rate of bromination of certain aromatic amino and phenolic organic compounds has been made by Francis, Hill and Johnston (*Jour. Am. Chem. Soc.*, Vol. *47*, p. 2211), which may lead also to methods of determining the rate of very rapid reactions. It has been shown that the rate of bromination is in harmony with the idea that there is intermediate substitution in the side chain. Directive influence of substituent groups is not easy to specify. Monobromphenol is produced preferentially in mixtures of bromine with equi molar phenol and aniline. Then tribrom-aniline is produced and finally tribromo-phenol.

Nitrogen Pentoxide.—The decomposition of this compound has again received extended experimental investigation (Hirst, *Jour. Chem. Soc.*, Vol. *127;* White and Tolman, *Jour. Am. Chem. Soc.*, Vol. *47*, p. 1240; Hunt and Daniels, *ibid.*, Vol. *47*, p. 1602). The new work confirms the older view of Daniels and Johnston (*Jour. Am. Chem. Soc.*, Vol. *43*, p. 53), that the process is truly unimolecular, the velocity of decomposition being independent of molecular collisions or pressure over a 7,000 fold variation in the latter. The mechanism of the decomposition process is again a matter for discussion since various efforts to promote its decomposition by infra-red radiation introduced photochemically have failed to accelerate the decomposition process at a given temperature. The literature on the radiation theory grows apace (G. N. Lewis and Smith, *Jour. Am. Chem. Soc.*, Vol. *47*, p. 1508; Tolman, *ibid.*, Vol. *47*, p. 1524; J. Rice, *Faraday Soc. Symposium*, Oct., 1925), without much material progress, beyond an abandonment of the simple theory that only a single infra-red wave-length has any activating efficiency.

Nitroso-Nitrogen Trioxide. — A new oxide of nitrogen has been prepared by R. L. Hasche (*Jour. Am. Chem. Soc.*, Vol. *47*, p. 2143), from the interaction of nitric oxide and oxygen at liquid air temperatures. It has the formula $(N_3O_4)_x$ and evidence is given which suggests that x=2. Such a peroxide is presumed to be an intermediate in the oxidation of nitric oxide, a reaction which shows a negative temperature coefficient, which abnormality can best be explained on the assumption that such an intermediate is more stable at lower temperatures.

Chlorine Hexoxide. — Bodenstein, Harteck and Padelt (*Z. unorg. Chem.*, Vol. *147*, p. 233), have confirmed the existence of Cl_2O_6, a deep red liquid formed by exposing ClO_2 to light. Its m.p. is $-1°$; density $= 1.65$ and reacts violently with water, forming chloric and perchloric acids. It ignites wood and alcohol and is highly explosive when mixed with other chlorine oxides. It is also formed by the action of red light on a mixture of ozone and chlorine, but not by blue light, which causes chlorine activation and ozone decomposition.

Ozone Decomposition.—There has been a renewed interest in the decomposition of ozone, which is one of four known bimolecular homogeneous thermal gas reactions, the others being the decomposition of hydrogen iodide, nitrous oxide and chlorine monoxide. It has long been known, also, that ozone is sensitive to ultra violet light. Recently it was shown by Griffith and Shutt (*Jour. Chem. Soc.*, Vol. *123*, p. 2752), that it was sensitive to red light also. Griffith and MacWillie (*Jour. Chem. Soc.*, Vol. *123*, p. 2767), indicated that this reaction was accelerated by admixture of such gases as helium, argon, nitrogen, carbon dioxide which might have been regarded as inert constituents. Griffith and McKeown have recently shown (*Jour. Chem. Soc.*, Vol. *127*, p. 2086), that the thermal reaction is similarly sensitive to such "inert" admixtures. The problem arises as to what is the mechanism of this interesting "catalysis." Kistiakowski has recently shown that all these gases inhibit, but less so than oxygen. A negative effect is attributable to the oxygen concentration. These several factors raise interesting questions as to the mechanism of bimolecular reactions and the energy exchanges between molecules on collision with one another (Christiansen, *Z. physik. Chem.*, Vol. *113*, p. 35; Born and Franck, *Z. Physik*, Vol. *31*, *p.* 411), a problem allied with the sensitisation of photochemical reactions and the extinction of fluorescence, e.g., of mercury, by admixture with foreign gases (Stuart, *Z. Physik.*, Vol. *32*, p. 262).

Water Vapor as Catalyst.—Baker and Carlton (*Jour. Chem. Soc.*, Vol. *127*, p. 1990), have studied once more the combination of hydrogen and oxygen under the influence of ultraviolet light and have shown that when thoroughly dried by standing for 13 weeks in contact with phosphorus pentoxide in quartz vessels, they do not combine under the influence of the light of the mercury vapor arc.

Theories of Solution.—The Debye-Hückel theory of electrolytic solutions continues to dominate the field of research in solutions. In their early papers Debye and Hückel (*Z. Physik.*, Vol. *24*, pp. 185 and 334), employing the assumption of complete dissociation of strong electrolytes, were able to show that the activity coefficients of electrolytes in dilute solution could be represented in terms of an internal electrical energy caused by interionic attractions between an ion of a given sign and an excess of ions of opposite sign, obeying Coulomb's Law, over those of the given sign, surrounding it. In the earliest work the ions were considered as point charges and the equations derived for the osmotic coefficient, activity and the like were only applicable in the extremest dilution. Corrections were next introduced for ion diameters and a corresponding gain in the range of applicability was demonstrated. For concentrated solutions of strong electrolytes a further modification of the simple theory is required, according to Hückel (*Z. Physik.*, Vol. *26*, p. 93), which may be regarded as taking care of the "salting-out effect" which ions exercise on neighboring ions in the way that ions act on neutral substances. This "salting-out effect" of ions on ions is superposed on the primary electrical attractions. With neutral molecules, no such electrical attractions exist and the effect is a linear function of the concentration. The combined effect of electrical attraction and "salting-out" of ions on ions is to yield a curve in which the activity first decreases with increasing concentration following the law for dilute solutions, then increases to values considerably greater than the activity in infinite dilution. The theoretical equation to interpret this behavior contains in addition to the ionic attraction terms already discussed, a "salting-out" term which involves primarily the change in dielectric constant and the reciprocal of the ionic size. This equation is applicable to univalent electrolytes over the whole range of concentration. A resumé of this work with full discussion and equations is given in a recent text (Eucken, Jette and La Mer, *Fundamentals of Physical Chemistry*, N. Y., McGraw-Hill, pp. 323-348). Scatchard has shown (*Jour. Am. Chem. Soc.*, Vol. *47*, p. 651), that available data both in aqueous and non-aqueous solutions confirm the Debye-Hückel theory as completely as the accuracy of the data permits. The theory has stimulated a great deal of new investigation on the subject of dielectric constants of solutions, e.g., by Walden.

Dissociation of Water in Salt Solutions.—Harned (*Z. physik. Chem.*, Vol. *117*, p. 1), has applied his studies of amalgam cells to the calculation of the dissociation of water in solutions of sodium and potassium chlorides. He finds that the dissociation increases rapidly at first, in agreement with the earlier Arrhenius view, passes through a maximum and then diminishes. The maximum occurs around 0.5 molar salt concentration and the dissociation is some 38 per cent. greater than in pure water. Schreiner (*Z. unorg. Chem.*, Vol. *135*, p. 333) reaches similar conclusions, his maximum increase in the dissociation amounting to 60 per cent. at the same concentration, viz., 0.5 mm. In a 2.1 molar solution the water would have the same dissociation constant as in pure water. In this paper, Harned also discusses his results from the standpoint of the Debye-Hückel theory.

Methanol Synthesis.—The outstanding development in applied physical chemistry is the synthesis of methanol from hydrogen and carbon monoxide

$$2H_2 + CO = CH_3OH$$

by a high pressure reaction of the ammonia synthesis type. Calculation shows that the equilibrium is in this case more favorable than with ammonia, operating pressures of upwards of 50 atmospheres giving practicable yields. As catalysts various oxides such as zinc, chromium and manganese oxides are suggested in patents to the Bädische Company and in literature recording developments in France.

BIOLOGICAL AND FOOD CHEMISTRY

By Arthur W. Thomas
Professor at Columbia University

VITAMINS

Five Vitamins.—Attention has been focussed principally upon what was formerly termed the fat-soluble vitamin (Vitamin A), now recognized to consist of at least two vitamins (Vitamins A and D). In general five vitamins are now recognized as essentials to proper animal nutrition, well-being and growth, as follows:

Vitamin A.—The anti-zerophthalmic vitamin, essential for health and growth.

Vitamin B.—The anti-neuritic vitamin, essential for health and growth, and an appetite stimulant.

Vitamin C.—The anti-scorbutic vitamin without which human and certain other animals develop scurvy.

Vitamin D.—The anti-rachitic vitamin, essential to bone growth. The effects of this vitamin are obtained also from ultra-violet rays. (See Irradiation, below).

Vitamin E.—The anti-sterility vitamin. The importance of this vitamin for reproduction has attracted much attention. It should be noted, however, that it is no more important in this sense than Vitamins A and B, but is characterized by the fact that whilst A and B possess other qualities, E is solely an anti-sterility factor.

Vitamin A.—Anti-zerophthalmic.—The bodily storage of Vitamin A as influenced by age has been shown by Sherman and Storms (*Jour. Amer. Chem. Soc. 47*, 1653). Among animals coming from the same previous diet, age was found to have an important influence upon the length of the survival period upon food devoid of vitamin A. The maximum body store of vitamin A was found at six months of age, or about at the beginning of full adult life.

Significant data concerning the relation of vitamin A to growth, reproduction and longevity are to be found in the paper by H. C. Sherman and F. L. MacLeod (*Jour. Amer. Chem. Soc. 47*, 1658). A proportion of vitamin A in the food sufficient to support normal growth and maintain every appearance of good health, for a long time at least, may still be insufficient to meet the added nutritive demands of successful reproduction and lactation. Along with the failure to reproduce successfully there usually also appeared in early adult life an increased susceptibility to infection and particularly a tendency to break down with lung disease at an age corresponding to that at which pulmonary tuberculosis so often develops in young men and women. The bacillus involved is different; but the close parallelism of increased susceptibility of the lung to infection at this stage of the life history appears very significant, especially in view of the fact that the vitamin-A content of lung tissue varies with that of the food. Thus it is clearly shown that vitamin A is an even more important factor in the chemistry of food and nutrition than has previously been appreciated, for it must be supplied in liberal proportion not only during growth but in the food of the adult as well, if a high degree of health and vigor are to be maintained.

Vitamin B.—Anti-Neuritic.—Study of the effect of vitamin B deficiency on reproduction by Parkes and Drummond (*Proc. Roy. Soc. London 98B*, 147) reveals that the reproductive power of the buck rat degenerates in a short time when the animal is placed on a ration totally deficient in vitamin B.

Vitamin C. — Anti-scorbutic. — Investigations by Delf (*Biochem. Jour., 19*, p. 141) afford information concerning stability of vitamin C. When whole fruits (oranges or lemons) and tuberous roots are stored their vitamin C value is retained as long as the tissue itself remains living. Expressed juices of oranges and lemons which have been stored for five years in the frozen condition retain about half their original vitamin C value.

Vitamin E.—Anti-Sterility.—The significance, properties and occurrence of vitamin E as shown by Evans were reported to the National Academy of Sciences in April (H. M. Evans and G. O. Burr: *Proc. Nat. Acad. Sci. 11*, 334).

If normal rats are shifted to a ration deficient in vitamin E, they preserve their normal fertility for three or four months, when they lose it. Similarly, when sterile animals are cured with foods possessing the new vitamin, not only is the next gestation normal, but in some circumstances, the next two or three gestations.

The administration to sterile animals of foods or extracts of foods known to be twice to twenty times as rich in vitamin E as is required for the birth of living young does not increase litter size or weight, or in other ways improve the performance of the reproductive mechanism beyond normal limits. This is in consonance with what we know of the action of other vitamins, there being little or no reliable evidence of advantage from an abnormally high quota of them, yet absolute need of the minimal quota.

Vitamin E may be called fat soluble, though its range of solubility is far greater than that of ordinary fats. It is almost insoluble in water, yet its presence in watery solutions has been repeatedly encountered.

Vitamin E is remarkably stable to heat, light, air and many of the ordinary chemical reactions. It is so widely distributed in both vegetable and animal tissues that there is little likelihood of one's food being deficient in it.

Vitamin A.—Conditions for a more exact estimation of Vitamin A using the white rat as experimental animal have been described by Sherman and Munsell (*Jour. Amer. Chem. Soc. 47*, 1639).

A delicate color test for Vitamin A consisting of a momentary blue color upon treatment of an oil with arsenic chloride has been found by Rosenheim and Drummond (Biochemical Jour. *19*, 753).

Biosterin.—A contribution of exceptional merit is the preparation of an extremely potent vitamin A concentrate by the late Takahashi. (Takahashi, Nakamiya, Kawakami and Kitasato: *Scientific Papers* of the *Institute of Physical and Chemical Research* (*Tokyo*), Vol. *3*, No. 32, p. 81). This preparation which Takahashi believed to be a chemical substance is called Biosterin. Starting a normal animal on a vitamin-A-free diet, it was found that 0.000005 gm. of Biosterin daily effected a comparatively satisfactory maintenance of growth with no deficiency symptoms. The Biosterin from cod-liver oil is believed to be $C_{27}H_{44}O_2$. It is a reddish-yellow, viscous oily substance distilling under a pressure of 0.02-0.03 millimeters at 147° C.

Vitamin B.—Concentration of extracts containing vitamin B by Levene and van der Hoeven (*Jour. Biol. Chem. 65*, 483) led to a product containing 15 per cent. nitrogen and potent in daily doses of 0.1 mg.

Irradiation.—The discovery of the antirachitic powers of ultra-violet light has been developed further this year. Irradiation of hens for 10 minutes daily with ultra-violet light greatly increased amount of eggs laid and the hatchability of the same. The amount of lime in the shell was markedly increased as was also the antirachitic potency of the egg yolks. (Hart and Steenbock: *Jour. Biol. Chem. 65*, 579).

Leg weakness in chicks can be cured by short exposure to sunlight. (Bethke, Kennard and Kik: *Jour. Biol. Chem. 63*, 377).

Henderson (*Biochemical Jour. 19*, 52) caused a definite increase in the lime and phosphorus retention of a pig on a diet poorly balanced with respect to these inorganic constituents by subjecting the animal to carbon arc lamp irradiation one hour daily for twenty-four days.

The activation of oils by the shorter light waves (quartz mercury arc, open carbon arc, iron arc and sunlight) has shown that the antirachitic potency so produced resides in the unsaponifiable constituents of the oils. (Steenbock and Black: *Jour. Biol. Chem. 64*, 263). Fresh olive oil became very potent upon moderate exposure to ultra-violet rays, but became inactivated upon excessive exposure to them. An activated olive oil kept in the dark for ten months retained its activity. Cholesterol acted differently from oils in that prolonged irradiation did not destroy the antirachitic power conferred upon it by short exposures.

Phytosterol from cottonseed oil and cholesterol from brain tissue irradiated for thirty minutes in a one per cent. suspension in water protected against rickets when fed to rats on a low phosphorus diet. (Hess, Weinstock and Helman: *Jour. Biol. Chem. 63*, 305). In regard to the bearing of their results on the pathogenesis of rickets, they propose the following tentative hypothesis:

"It would seem quite possible that the cholesterol in the skin is normally activated by ultra-violet radiation and rendered antirachitic—that the solar rays and similar artificial radiations are able to bring about this conversion. This point of view regards the superficial skin as an organ which reacts to particular light waves (the epidermal organ) rather than as a mere protective covering. This suggested mechanism presupposes not only the formation of active cholesterol within the skin but its further transport by way of the circulation."

A continuation of this investigation (Hess and Weinstock: *Jour. Biol. Chem. 64*, 181) demonstrated that dry milk powder, flour and spinach can be rendered antirachitic by radiations from the quartz mercury vapor lamp. This potency was maintained by the spinach after it had been boiled one-half hour. Irradiated cholesterol prevents rickets when given by the subcutaneous route. The radiations which render cholesterol active are similar in their wave lengths (200-300 millimicrons) to those which have been found to protect animals against rickets when they are directly exposed to the rays. Irradiated cholesterol is effective in preventing the rickets brought about by a diet either low in phosphorus or low in lime.

One must be warned that vitamin D or the antirachitic potency conferred by short light rays is not solely a rickets cure or preventative. This principle effects greater lime and phosphorus retention and thus its antirachitic function is accounted for. That lime is a limiting factor has been strikingly shown by the researches of Sherman and MacLeod (*Jour. Biol. Chem. 64*, 429).

NUTRITION

General.—Most thorough studies of the physico-chemical property of solubility product of calcium phosphate afford more exact information concerning the significance of lime and phosphorus in nutrition and a new and more exact method of treating rickets. (Holt, LaMer and Chown: *Jour. Biol. Chem. 64*, 509).

Diet excessively rich in fat has been found to increase the blood uric acid. This is partly due to a decreased blood volume with a consequent decreased elimination. (Harding, Allin, Eagles and Van Wyck: *Jour. Biol. Chem. 63*, 37).

Protein.—The effects of excessively rich protein diets have been shown by Reader and Drummond (*Jour. Physiol. 59*, 472). On food mixtures containing 90 per cent. protein, rats failed to show normal growth at any stage and attained a constant weight of approximately 33 per cent. of the normal. No abnormalities of body structure were noted except hypertrophy of the kidneys.

The high nutritive efficiency of milk proteins in growth and that cystine is the first limiting amino acid of proteins of cow milk have been demonstrated. (Sherman and Merrill: *Jour. Biol. Chem. 63*, 331).

Blood Regeneration.—Beef liver has been found to be most excellent for blood regeneration in severe anemia (Whipple and Robscheit-

Robbins: *Amer. Jour. Physiol.* 72, 408).

While the feeding of inorganic iron will not correct a nutritional anemia, inorganic iron in conjunction with such iron-free alcoholic extracts as that of cabbage or of yellow corn-meal is effective. (Hart, Steenbock, Elvehjem and Waddell: *Jour. Biol. Chem.* *65*, 67) .

Protein Chemistry.—A new product of hydrolysis of certain proteins believed to be a hydroxylysine has been isolated (Schryver, Buston and Mukherjee: *Proc. Roy. Soc. London*, *98B*, 58).

Molecular Weights.—Studies of the physical chemistry of the proteins (Cohn, Hendry and Prentiss: *Jour. Biol. Chem.* *63*, 721) point to the following minimal molecular weights of certain proteins:

Gelatin	10,300
Zein	19,400
Gliadin	20,700
Hemocyanin (Limulus)	22,700
Bence-Jones protein	24,500
Edestin	29,000
Hemocyanin (Octupus)	33,500
Egg albumin	33,800
Glutenin	36,300
Fibrin	42,000
Serum albumin	45,000
Hemoglobin	50,000
Serum globulin	81,000
Casein	192,000

Enzymes.—Considerable interest has been aroused by the application of adsorption methods to the problem of isolation and purification of enzymes as proposed by Willstätter (Zeitschrift physiologische Chemie). Willstätter's claims are striking but confirmation is up to the present time lacking.

Boorsook and Wasteneys (*Jour. Biol. Chem.*, *63*, 563) have demonstrated the reversibility of the action of pepsin and trypsin action, *i.e.*, they have revealed conditions under which these enzymes synthesize protein matter from solutions of protein hydrolysis products.

It has been shown that pepsin acts like a univalent ion. (Northrup: *Jour. General Physiol.* 7, 603). Its adsorption by protein particles is irreversible and markedly influenced by the presence of low concentrations of electrolytes.

Further evidence has been produced in favor of the point of view that pancreatic amylase is protein in character. (Sherman, Caldwell and Naylor: *Jour. Amer. Chem. Soc.* *47*, 1702). The investigations by Scott (*Jour. Biol. Chem.* *65*, 601) point strongly to the protein nature of insulin.

SANITARY CHEMISTRY

By F. W. Mohlman

Chief Chemist, Sanitary District of Chicago

Better Standards.—The quality of public water supplies has been under close scrutiny in the year 1925. More stringent standards are being demanded by our larger municipalities and by our governmental agencies which are charged with the duty of controlling the quality of potable waters.

The United States Public Health Service has adopted a standard of quality that is, numerically, twice as stringent as the old standard. The new standard will not pass a supply which contains more than one bact. coli per 100 cubic centimeters; the old standard was two per 100 c.c. As the United States Public Health Service can forbid the use of rejected supplies on interstate carriers, the standard is applied indirectly to all of the more important municipal supplies, most of which are able to meet the new standard. Some filtered surface waters from contaminated supplies are not able to meet the standard unless the filtered water is chlorinated.

Chlorination has thus been a great aid in the improvement and safeguarding of water supplies. There is some feeling at the present time, however, that too much dependence is being placed on sterilization. Studies are being made to determine the limits of bacterial loading of filter plants and the factor of safety that can legitimately be left for sterilization.

Chlorine Tests.—Tests for residual chlorine have been improved and the control of chlorine dosage in our larger cities has been placed under more scientific control in the past year.

Notwithstanding the improvement in control, tastes and odors have been of more frequent occurrence and constitute a very serious problem in water purification. These tastes and odors may be due to various causes, such as the presence of microörganisms in unusual concentrations, or too great an excess of residual chlorine, but the most common source of obnoxious tastes and odors has been the presence of phenol-containing wastes in chlorinated waters. These wastes are discharged from by-products of coke plants, wood-distillation plants, and oil refineries. The obnoxious tastes are due to chlorphenols. They have been reported in as low concentration as 1 part (phenol) in 500,000,000, but most investigators agree that higher concentrations are necessary to become obnoxious.

Investigations of the nature and source of these wastes have been made at Milwaukee, Toledo, Cleveland, Chicago, Morgantown, W. Va.; McKeesport and Newcastle, Penn. The only satisfactory remedy seems to be complete removal of the phenol-containing wastes from water-courses and lakes. The wastes are used in some plants for quenching coke, and investigations have indicated that they can be treated biologically on trickling filters at very low rates, but very few coke plants are now recovering or treating their wastes.

Water Purification.—Studies have been made at various water-purification plants of the factors that control the formation of alum floc in the filtration of surface waters. The alum performs two functions, the removal of turbidity and the decolorization of surface waters. The zone of coagulation seems to extend over a rather wide range of hydrogen-ion concentration, with the optimum at a pH. of 5.5 units. Between 5.5 and 7.5 the precipitation and removal of aluminium-ion from solution is complete, with maximum removal of turbidity. For maximum removal of color the pH should be 5.5 or less. At several plants sulphuric acid has been used to lower the pH, with a reduction in the amount of alum required for coagulation. The effluents from alum-treated water are practically free from all the aluminium added as alum when the pH value of the treated water lies in the zone, between 5.5 and 7.5 units. Above and below these limits there is a possibility of soluble (colloidal) alum passing through a sand filter.

Water-Softening.—This has shown slight progress in 1925. Lime and soda ash are generally used for softening municipal supplies, while there has been a marked increase in the use of zeolites for softening laundry and institutional supplies. An interesting study has been made at the University of Chicago of the relative effect of distilled and hard water on the growth and bone structure of chicks, white rats, rabbits, dogs and calves. In almost all cases the test animals drinking hard water were heavier and had larger, stronger bones than those drinking distilled water.

Sewage Treatment.—Brief mention should be made of the great advance in the application of the activated sludge process in America, as evidenced by the new plants put in operation in 1925 at Indianapolis and Milwaukee (see Section on Sanitary Engineering). Interesting studies have been made at Milwaukee, Chicago and Pasadena concerning the pretreatment of activated sludge as an aid to filtration. The most satisfactory coagulants have proven to be filter alum (aluminium sulphate), sulphuric acid, and ferric salts. The filtrability of the sludge varies over wide limits, depending upon the degree of biological treatment and amount of air applied to the sewage. At times it would be economically impossible to filter the sludge without the use of the above-mentioned filter aids.

Detailed investigations have been made at the New Jersey Sewage Experiment Station, located at New Brunswick, N. J., on the biological, bacteriological and chemical phase of sewage treatment. Studies have been made of the operation of Imhoff tanks, trickling filters and separate sludge digestion tanks. Results indicate that the foaming of Imhoff tanks may be predicted by determinations of the per cent. of carbon dioxide in the evolved gases. The nitrification in trickling filters has been shown to occur in the lower part of the bed, within a foot or two of the effluent drains.

The work at the Lawrence (Mass.) Experiment Station and at the Illinois State Water Survey has been continued. Some work has been done at the Ames (Iowa) Experiment Station on the treatment of creamery wastes. The treatment of corn products' wastes has been investigated in great detail by the Sanitary District of Chicago.

River and Coast Pollution.—Reports have been issued in 1925 by the U. S. Public Health Service, giving the results of their investigations of the pollution of the Ohio River. A similar report has been issued by the Engineering Board of Review of the Sanitary District of Chicago concerning the pollution and self-purification of the Illinois River. These reports mark a noteworthy advance in the study of stream purification in America. The conception of the fundamental importance of a balance of the oxygen requirements and oxygen resources has been emphasized in both reports.

Oil pollution of coastal waters has been studied by the Bureau of Mines, in coöperation with the American Petroleum Institute.

A widespread epidemic of typhoid fever was proven to be due to contaminated oysters taken from sewage-polluted beds. An embargo was temporarily placed on oysters by various states, as a result of which the sanitary conditions surrounding the gathering and shipment of oysters were greatly improved. It is possible to purify oysters by storage in a bath of chlorinated water but this procedure has not been adopted for various reasons. Sanitarians are beginning to question the desirability of partial sterilization or pasteurization of foods and water, without consideration of the initial bacterial count. For example, there is a parallelism between the studies that have been made in 1925 on prepasteurization bacterial counts of milk, limits of bacterial loadings of water filtration plants, and the condition of raw oysters as affecting their desirability as a food.

Ventilation.—The control of humidity and dust content of air has made progress in 1925. The evidence is somewhat conflicting concerning the necessity for mechanical humidification, but most investigators agree that hot, dry air is less pleasant than air humidified to a moderate degree, and that the control of humidity is the most important single factor in air conditioning. It has been shown that the carbon dioxide content of air is of slight importance and that discomfort is rarely caused by high concentrations of this gas. The effect of unpleasant odors on health has been investigated, but aside from some influence toward loss of appetite no direct detrimental effect has been demonstrated.

Methods for detecting carbon monoxide in mine air have been improved so that it is now possible to make a quantitative determination in a few minutes. The removal of inorganic dust is an important factor in industrial hygiene.

The chlorine treatment for respiratory infections has been studied at length. While there has been some evidence from clinical records that the method has value, controlled laboratory tests have indicated that the germicidal action of the chlorine is neutralized by its combination with the mucous membranes of the upper air passages, and that concentrations necessary for sterilization are far too toxic.

AGRICULTURAL CHEMISTRY

By C. A. Browne

Bureau of Chemistry, U. S. Department of Agriculture

Agricultural chemistry in its present generally accepted meaning treats of the composition of soils, crops and animals and of the mutual chemical relations of these in so far as they concern the production of the means of human subsistence and comfort. It is a comprehensive term which includes not only much of chemistry but touches also upon mineralogy, physics, meteorology, plant and animal physiology, mycology and other correlated sciences. There is no field of applied chemistry which is broader in its scope or more comprehensive in the circle of its numerous bearings than that pertaining to agriculture.

Fertilizers. — Modern agricultural chemistry may be said to date from the researches of Liebig who, just a century ago in the famous laboratory which he established at Giessen, began a series of epoch-making discoveries that changed the entire future of scientific husbandry. By new methods of analysis which he devised Liebig determined for the first time the chemical composition of many plant and animal substances. He was the earliest to discern clearly the basic requirements of crops for nitrogen, phosphorus, potassium, calcium and other mineral constituents. The importance of bones as a fertilizing material had been known for centuries but it was only after Liebig in 1840 proposed the treatment of insoluble phosphates with sulphuric acid, in order to make them more readily available to crops, that the great modern industry of commercial fertilizers began.

The supplying of crops with the necessary amounts of raw materials, from which they can synthesize the maximum quantity of starch, cellulose, sugar, fat, protein, alkaloid, essential oil, dye stuff, or other desired ingredient, has been, and will always remain, the great basic problem of agricultural chemistry. The determination of the nature and quantity of this supply for each individual crop is the purpose of fertilizer plot experimentation, a method of research which in its present form was originated by Lawes and Gilbert at Rothamstead in 1843 and is now pursued in every agricultural experiment station of the world. The method is to test the particular crop with applications of varying known amounts of ammonium salts, nitrates, phosphates, potassium salts, lime, etc., singly and in combination until the best mixture is found for securing a maximum yield on a given soil under a given method of cultivation. The possible combinations of mixtures and the possible effects of rainfall, temperature, cultivation, rotation, drainage, etc., introduce so many variables into plot experimentation that the interpretation of the results is rendered extremely difficult.

Minimum and Diminishing Returns.—Two much discussed laws in fertilizer experimentation are the "law of the minimum," first announced by Liebig, and the "law of diminishing returns." The "law of the minimum" teaches that the yield of a crop is limited by the amount of the minimum essential constituent which is present in the soil whether it be nitrogen, potash, phosphoric acid, lime, water or other ingredient. If nitrogen, for example, is the deficient constituent, then no increase of phosphoric acid, potash, or other fertilizing substance will materially benefit the crop. The "law of diminishing returns" teaches that, after a certain maximum, additional increases of fertilizer, although perhaps at first financially remunerative, give proportionately smaller increases of crop until finally a point is reached beyond which further additions cause no increase of yield.

The "law of diminishing returns" has given rise to a vast amount of discussion among agricultural economists, for it is the principal determining factor as to the profitable limit to which crops can be fertilized for increased production. Obviously the profitable limit will vary according to the relations between the costs for labor, seed, fertilizer, transportation, etc., and the selling price of the farm commodity. The "law of the minimum" and "the law of diminishing returns" are of broad fundamental importance since they apply not only to crop fertilization but to cattle feeding and many other operations of agriculture.

The possible future shortage of food supplies, with the increase of the world's population, with the gradual decrease of soil fertility and with the constant depletion of available fertilizing materials, has given rise to frequent prophecies of disaster. Everyone will recall the warning of Sir William Crookes in his presidential address before the British Association in 1898 with respect to the rapid exhaustion of the world's supplies of combined nitrogen for agricultural uses. While this particular danger has been largely averted by the recent discovery of commercial methods of fixing atmospheric nitrogen, there is cause for future apprehension in the case of potash and phosphoric acid, which have no such unlimited storehouse of reserves.

Problem of Exhaustion.—The problem of the exhaustion of the world's natural phosphorus and potassium resources must sooner or later be faced. The losses of these important elements to American agriculture in the exportation of grain, in the sewage of cities, and in other wastes cannot continue indefinitely. The restoration of our soils to their maximum fertility will become increasingly important as the density of our population grows. American agriculture with its cheap land and high cost of labor has been obliged to reckon production upon the basis of bushels of grain per man rather than upon the European basis of bushels of grain per acre. The United States in the future must turn more and more to intensive methods of cultivation and the adaptation of American farming to this system will be one of the chief problems to engage the attention of our agricultural chemists.

Minute Influences.—The formation of carbohydrates, fats and proteins from their elementary components may be termed the chief functions of our agricultural crops. But in the performance of these major activities various complicated side-reactions take place. Although the substances formed in these secondary processes may be insignificant in amount they can be of great importance both to the advantage and to the disadvantage of the plant. The essential oils of the cotton blossom, for example, exist only in minute quantities yet they are supposed to perform a most useful function in attracting the bees and other insects that effect pollenization. Odorous volatile substances emanating from other portions of the plant may, however, act injuriously in attracting the boll-weevils which do serious damage to the crop. This attracting action of a chemical substance for insects (chemotropism), is so powerful that a single cotton plant growing alone will give off emanations, unweighable in amount, but sufficient to attract weevils from a long distance. Power and Chestnut of the Bureau of Chemistry have isolated no less than fifteen volatile odorous substances that are given off by the cotton plant, one of which (trimethyl amine) has been found to act as a powerful attractant for the weevil. The employment of such attractants as baits, for living weevils and other insects of destruction, is now being investigated by the United States Department of Agriculture.

Soil Study.—The field is so vast that it is possible to indicate only very briefly a few of the agricultural chemical problems that await solution. The agricultural chemist is not concerned, as in the early days, with the mere chemical analysis of soils and crops and animals, but rather with the dynamic rôle which is played by the constituents in the soil solution and in the fluids of the living organism. He does not consider the question of fertilizing for the increased production of grain or seed alone, but also for the increased yield of oil or carbohydrate or protein. The old problems of the formation, chemical composition and significance of the humus ingredients of the soil are being restudied. The influence of the acidity and alkalinity of soils upon crop production is being reinvestigated by the aid of more refined methods of analysis. New chemicals are being examined as insecticides and fungicides for protecting crops against the countless enemies which threaten above and below the ground.

Food Values.—The importance of the different vitamins in the diet of men and animals is at present one of the leading subjects of agricultural chemical investigation, but the chemical nature of these highly necessary food constituents is almost wholly unknown. The different vegetable proteins vary in their content of the amino acids essential to proper nutrition and more extensive researches are being conducted to determine the best sources of these dietary requirements. Much new light has been thrown by recent researches, in the United States and elsewhere, upon the economic feeding of farm animals but there are many problems that still remain to be solved regarding the most profitable methods for producing meat and milk. Great attention is also being given by chemists to the improvement of means for preventing the deterioration and decay of agricultural products and to the discovery of better processes for utilizing surplus crops and agricultural wastes.

Research Institutions.—The Federal Department of Agriculture and the State Agricultural Experiment Stations are the leading institutions in the United States for promoting agricultural chemical research. In addition to these organizations there are universities and private establishments that are conducting investigations in agricultural chemistry. The late Mrs. Herman Frasch left a generous bequest for supporting original research in this field and this is only one of many indications of the growing realization, in the mind of the general public, of the great importance of this branch of agricultural science.

ELECTROCHEMISTRY

By Colin G. Fink
Professor at Columbia University

Results.—The year 1925 has been a noteworthy one in the history of the American Electrochemical industry. Prominent among the achievements is the production of a new aluminum of the highest grade of purity; the establishment of an iron tube factory at Niagara Falls for the direct manufacture of tubes by electrolytic means; the successful completion of years of research, resulting in a new metal, thorium, extremely malleable and ductile, readily rolled into sheets and drawn into wire; the large scale commercialization of chromium plating; marked improvements in the electrodeposition of nickel; the ever-increasing use of the electric furnace of the induction type; and a new electrolytic rectifier using tantalum electrodes.

Electric Furnaces.—There are now over 500 electric steel furnaces in operation in the United States, as compared with 19 furnaces in 1913. The American electric steel industry is the foremost of the world. Aside from the many new arc furnaces installed, an interesting factor was the installation of a number of 800 kw. ring type horizontal induction furnaces, of six-ton capacity.

In the non-ferrous industry the rapid expanse in the number of electric furnaces has been phenomenal. The induction furnace which had met serious objections in the steel foundry has proved an unqualified success for the production of brass and other non-ferrous alloys. Fuel-fired melting furnaces are rapidly passing out of existence, being supplanted by the more efficient electric furnaces, such as the Ajax-Wyatt, of the induction type, and the Detroit Electric Furnace of the indirect arc type. For the production of metals and alloys requiring special precautions, the Northrup high frequency furnace is meeting with increased favor. An improvement in the large installation is the replacement of the oscillatory spark gap by the new high frequency generators.

Of the various electric furnace products, next to those of steel and brass, the ferro alloys command a domineering position. Important among these are ferro-silicon, ferrochromium, ferro-tungsten, and ferrovanadium.

Fused Electrolytes.—In the fused electrolyte field the outstanding accomplishment has been the production of a new aluminum. This metal analyzes 99.8 per cent. aluminum, as compared to 99 per cent. of the ordinary aluminum. This result of years of research is reported upon by Messrs. Francis C. Frary and J. D. Edwards, the new cell having been originally designed by Wm. Hoopes. In the new cell, the anode consists of a molten aluminum alloy, containing small percentages of copper, besides a number of other impurities. The electrolyte is a fused mass containing barium fluoride, sodium fluoride, and aluminum fluoride, besides small quantities of calcium and magnesium fluorides. Bauxite is introduced into the bath and is soluble to the extent of about 2 or 3 per cent. The cell operates at about 6 volts and 20,000 amp. The new aluminum holds its bright luster in the air almost indefinitely and is only slowly soluble in dilute hydrochloric acid, whereas ordinary aluminum is readily attacked by this acid. The physical characteristics of the new metal are quite distinct from those of ordinary aluminum.

Wm. G. Harvey, of the American Magnesium Corp., presented for the first time the details of the new process for making pure magnesium. This new process uses a fused fluoride bath in contradistinction to the older chloride bath. The magnesium made by this new process analyzes 99.9 per cent. purity and is very stable in the air, so that fine ribbon and wire will not disintegrate readily, as has been the case with the imported material in the past. The importance of magnesium in the metallurgical art is largely due to its lightness. It finds wide application in the construction of aeroplane parts.

A newcomer in the fused electrolyte field is beryllium, now being made commercially by the Beryllium Corp. of America. Beryllium added to magnesium results in alloys of valuable mechanical properties.

Among the academic researches in the fused electrolyte field, those of Prof. H. C. Kremers, of the University of Illinois, and those of Dr. H. H. Kahlenberg, of the University of Wisconsin, deserve special mention.

Aqueous Electrolytes.—The Niagara Electrolytic Iron Company started production of pure iron tubes by the electrodeposition of iron on a steel mandrel. The process is a modification of the Boucher-Bouchayer process, which has been in commercial operation at Grenoblé, France, for a number of years. From 7 to 10 tons of iron tubes are produced per day. After annealing, these tubes are extremely malleable.

Heavy deposits of nickel, 20 and 30 mil thick, free from pits and other flaws, are now being made by the Madsen and the Hybinette processes. The success is due largely to the efficient elimination of the hydrogen by means of strong oxidizing agents serving as cathode depolarizers. The Bureau of Standards and other laboratories made a thorough investigation of the protective value of nickel and other metals. The Bureau has suggested a number of improvements in the bath and its manipulation.

In the plating field, the protection of steel by electrodeposits has been the main consideration. C. J. Wernlund developed an improved method of electrogalvanizing, using a small amount of mercury in the zinc cyanide bath. Similarly, Dr. Wernlund has developed a new cadmium plating bath, using a small amount of mercury in the bath. Besides the Roessler and Hasslacher Company, the Udylite and Grasselli Companies have each developed a commercial process for the electrodeposition of cadmium on steel and other metals.

The year witnessed the extended commercialization of chromium plating and there are several large plants in operation at present, turning out a big variety of chromium plated products. Chromium plate is extremely hard—a steel file will not touch it. It is permanently resistant to corrosion and also resistant to oxidation at high temperatures. It can be produced either in a bright mirror finish, requiring no polishing, or a dull satin finish. Its color approaches that of platinum.

H. D. Hineline and W. B. Cooley carried out to successful completion the simultaneous deposition of copper and nickel on steel and other metals, thus producing a coating of an alloy similar to that of Monel, highly resistant to atmospheric and other corrosion.

Mr. R. G. Bowman, of the Anaconda Lead Products Company published the details of the new Sperry process for the electrolytic production of white lead superior in quality to that produced by the older process.

S. J. Lloyd and A. M. Kennedy announced a new method for the electrolytic production of calcium arsenate. A sodium hydrate solution is electrolyzed between iron electrodes.

Electrolytic Cells.—The manufacture of dry cells of the Le Clanché type has reached hundreds of millions per annum, due largely to the universal demand by the radio "fans." In some of the newer dry cells, magnesium is used instead of zinc.

The storage battery industry likewise experienced a very profitable year, due not only to the rapid growth of the radio industry, but also to the continued phenomenal growth of the automotive industries. According to G. W. Vinal, one of the most notable achievements in the storage battery field has been the production of thin plate storage batteries for aeroplane service of greatly increased capacity.

A very convenient and serviceable type of Weston Standard Cell has been developed by W. C. Vosburgh and Marion Eppley. This is a portable cell of the "H" type. By mixing pure asbestos fiber with the sulfate of mercury paste, the portability of the cells has been greatly increased without materially effecting the hysteresis. The temperature co-efficient of the new cells is very low.

Organic Electrochemistry. — Although Germany has for some years been carrying out commercially the electrolytic production of organic chemicals, here in America we have been rather reluctant in adopting these methods. At present there are two plants operating successfully, producing organic compounds electrically. During the year patents were granted to Messrs. H. G. Byers, W. D. Van Arsdell, and G. A. Richter for the electrolytic manufacture of chloroform. Nascent hydrogen is brought into reaction with carbon tetrachloride dissolved in 95 per cent. alcohol. The carbon tetrachloride is reduced to chloroform.

A very interesting announcement was made by S. E. Sheppard and L. W. Eberlin, of the Eastman Kodak Co., electrodepositing rubber on various metals. A solution of rubber in an organic solvent is emulsified in an aqueous solution of soaps, or equivalent emulsifiers, the mixture being thoroughly agitated and homogenized by spraying or grinding. The bath has very good throwing power. For the electrodeposition of rubber, a current density of about ½ ampere per square decimeter is used. Rubber has been very successfully plated upon lead, cadmium, zinc, tin, antimony, and certain alloys of these metals; also upon iron and steel under certain conditions. Copper and copper alloys are usually unsuitable.

Corrosion.—The subject of corrosion of iron and steel has become of increasing economic importance and nearly every large research laboratory in the world is investigating some phase or other of this problem. Within the last year or so there has been a general adoption of the theory that all corrosion of metals, almost without exception, is electrolytic. As pointed out under electroplating, above, careful investigations have been carried out in the plating of cadmium, nickel, zinc, and chromium on iron and steel, in order to assure permanent protection of the ferrous metal. An interesting application that has come into commercial use is the electrolytic protection of boilers and other metal apparatus, worked out by Alexander Kirkaldy and his associates. The boiler shell, or metal parts of other apparatus, is maintained at a definite cathodic potential. One or more iron anodes are introduced through the boiler shell by means of a specially devised insulator. The entire corrosion centers in these anodes, which are renewed from time to time.

Another application of electrolysis has been worked out by Colin G. Fink and Chas. H. Eldridge in the restoration of ancient bronzes. The bronze object is made cathode in a weak alkaline solution and feeble currents are passed through the electrolyte.

The Fixation of Atmospheric Nitrogen has been one of the most fruitful applications of electricity to chemistry. For many years in the past the only source of supply of nitrates in large quantities has been the caliche deposits of Chile. Aside from the demand for agricultural purposes, there is a constantly increasing demand by various industries, such as dyes and explosives. The American Electrochemical Society at its September Convention (1925) devoted an entire day to the discussion of the nitrogen problem. By the synthesis of nitrogen and hydrogen, ammonia can now be produced for 2¼¢ per pound. However, ammonia cannot be applied to the soil directly and must be combined with some acid, such as phosphoric acid. At this convention, H. K. Benson described the manufacture of sodium nitrite by the arc process, as carried out by the American Nitrogen Products Company, of Seattle, Wash. Air is passed through an electric arc and the nitrogen is oxidized to nitrous oxide. This is brought in contact with water to form nitrous acid, and subsequently this acid is neutralized with sodium carbonate to form sodium nitrite.

Phosphoric acid, which is brought into reaction with ammonia to form ammonium phosphate, is being produced on a large scale in an electric furnace at Anniston, Ala. To meet the increasing cost of transportation, the phosphate fertilizers should preferably be in a concentrated form, such as ammonium phosphate, potassium phosphate, or calcium phosphate. Heretofore 80 per cent. of the compounds in phosphate fertilizers were of little or no fertilizer value.

Ozone.—During the year patents were issued to F. E. Hartman for an improved method for the production of ozone. Air under pressure is supplied to an ozone generator and gases are obtained containing a high concentration of ozone.

Photo-Electric Cell.—A study of the electrical behavior of metal vapors has resulted in a new photo-electric cell, using either sodium or potassium vapor. This cell has the outward appearance of an ordinary incandescent lamp and has been termed the "photo-electric eye." It is more sensitive than the familiar selenium cell.

Power for Electrochemical Industries.—The question of large blocks of cheap power for electrochemical industries continues to be the most fundamental of all problems. F. A. J. FitzGerald published a splendid survey of the entire power situation before the World Power Conference, held at London in 1924. During the year 1925 the Muscle Shoals Plant put into operation its first generator unit. Noteworthy developments have been going on along the Pacific Coast, in particular the development of the Pitt River and the construction of the Pitt River dams. Dam No. 4 is now nearing completion.

CHEMICAL ENGINEERING

By H. C. Parmelee

Editor of Chemical and Metallurgical Engineering

Advances. — Chemical engineering was recognized as a factor in industry to a greater extent in 1925 than in any preceding year. In educational circles chemical engineering gained increased recognition as a separate branch of engineering, while in the industrial field it was proved to have a wide application in the most diverse industries. Thus a certain group of industries became more definitely recognized as chemical engineering industries, because clearly based on the common use of the processes and principles of chemical engineering. Chief among them were the manufacture of heavy and fine chemicals, coal products, explosives, petroleum products, fertilizers, paper and pulp, sugar, insecticides, wood distillation products, paint and varnish, soap, lime and cement, ceramics, rubber, leather and food products. The adoption of chemical engineering principles resulted in great strides toward putting these industries on a scientific basis and taking them out of the realm of rule-of-thumb and empiricism.

Industrial Organic Syntheses.—The most striking developments of the year were made in the synthetic production of several basic materials of commerce formerly obtained only from natural sources and by long-established processes.

Thus nitrogen from the air was fixed in the form of ammonia in this country to the extent of 30 short tons per day, and new plants under construction during the year were expected to double this production early in 1926. Synthetic ammonia thus produced practically captured the liquid anhydrous and aqua ammonia markets and greatly demoralized prices which had been stable for many years. No synthetic ammonia found its way directly into fertilizer production, although by displacing a portion of the by-product ammonia from coke ovens it made available more of this domestic product for competition with the sodium nitrate which the fertilizer industry must import from Chile. It would be too optimistic, perhaps, to say that synthetic ammonia would soon render this country entirely independent of foreign sources for its nitrogen supply, but certainly real progress was made in that direction during 1925.

Synthetic wood alcohol, now called methanol, has been made in Germany from water gas which in turn is obtained from coal. It found its way into the American market early in 1925 and while no domestic production was made during the year, plans were initiated that will doubtless give substantial domestic production in 1926. The production of synthetic acetic acid from acetylene, which had been made in Canada since the war, was undertaken as part of a large program adopted by a combination in which several American companies participated. Developments in both of these chemicals had their effect on the American wood chemical industry which, in spite of tariff protection, has felt the competition of these newer products of synthetic organic chemistry.

Rayon, the synthetic chemical fibre made from cotton or wood pulp, had a most striking development during the year. American production in 1925 increased 40 per cent. over 1924 and 600 per cent. over 1920. The estimated 1925 production was 57,000,000 pounds, or 30 per cent. of the world's output. Authorities in the industry estimated that the 1926 production would reach 75,000,000 pounds.

Nitrocellulose lacquers for metal and wood finishing largely displaced surface finishes in the automobile industry and bade fair to extend their application. The first large-scale commercial production of this typically American development occurred early in 1924, when 45 plants produced 2,160,300 gallons. In the first six months of 1925 the production was 4,880,200 gallons, or more than double the total production of the preceding year. The number of manufacturers increased to 67. Coincident with the development in lacquers was a marked increase in the production of solvents—butanol, made from corn, anhydrous ethyl alcohol by the fermentation of molasses, and its derivative, ethyl acetate.

American Dye Industry.—Dyes became more firmly entrenched during the year, devoting a large fund to research, increasing the number of dyes and reducing prices. It is safe to say that of the apparent consumption in the United States, the domestic industry supplied 95 per cent. and imports 5 per cent. There was a large exportable surplus of certain dyes, chiefly indigo and sulphur black. The number of producers was 78.

Corrosion.—The prevention of corrosion received a vast amount of attention at the hands of organized engineering societies and individuals. In the realm of theory many conflicting ideas were harmonized and there was a general acceptance of the electrolytic theory of corrosion. On the practical side there was a general recognition of the fact that what is needed is more actual data on the effects of corrosion and the development of materials of construction to withstand its ravages.

For purposes of study six types of corrosion have been recognized: 1, corrosion of cast iron pipe buried in soil; 2, atmospheric corrosion; 3, natural water corrosion; 4, salt water corrosion; 5, acid corrosion and 6, alkali corrosion. These types are of interest to well-defined groups of industries. Thus subsurface pipe corrosion which is being tested by the Bureau of Standards is of special interest to public utilities transporting liquids and gases. Atmospheric corrosion affects outdoor structures of all kinds. Natural water corrosion is of concern to public water systems with respect to the inside of the pipe. It has been demonstrated that this can be successfully combatted. Marine architects are confronted with problems in salt-water corrosion and the petroleum industry meets the same problem in certain oil fields in which salt water occurs with the oil. Acid and alkali corrosion are of primary interest to the chemical manufacturing industry and others using those materials in their processes. As materials of construction, acid-resisting alloys are receiving most attention and give hope of solving many of the problems. Another line of investigation is the development of protective coatings that can be used on cheap base metals. Chromium plating, which was commercially developed in 1925, falls in this class of materials.

Coal Carbonization.—While there were no new striking commercial developments in this field of chemical engineering there was considerable experimentation in the processing of coal, in harmony with the world-wide interest in this subject. The use of water gas as a raw material for methanol and as a source of hydrogen for synthetic ammonia was indicative of a trend in the use of coal as a raw material for the chemical industry. The Pier process for generating water gas from caking bituminous coal was perfected during the year. The Koppers Company also developed a vertical retort for high-temperature carbonization for use in the manufacture of domestic gas in small units. With respect to low-temperature carbonization there was a general recognition of the fact that what is needed to meet conditions in the United States is a method of carbonizing at medium, rather than low temperatures in order to obtain better yields of ammonia, phenol an cresol by-products. The present development is toward carbonization a 800° C. which lies between th low and high temperature ranges o about 600° C. and 1100° C., respectively.

Fertilizers.—In the production o mixed fertilizer there was a tren toward more concentrated types wit double the usual percentage of potash, phosphoric acid and ammonia Looking toward still further concentrated fertilizers there was production on an experimental scale of phosphoric acid by the Liljenroth proces and urea by the Lidholm process The former consists in producin phosphorus in an electric furnace an treating the product with steam i the presence of a catalyst, yieldin phosphoric acid and hydrogen. Th latter can be used for ammonia synthesis while the former can be combined with ammonia to form ammonium phosphate. The Lidholm process for urea makes use of calcium cyanamid as a raw material.

Economics of Chemistry.—The trend of chemical prices throughou the year was on an even keel according to the weighted index of *Chemica & Metallurgical Engineering*, the index ranging from 112 to 116 (1913-1914 basis equals 100). There was an upward trend of production and operating efficiency per wage earner due largely to improved technology and mechanization of industry. Foreign trade expanded in comparison with 1924. During the first nine months of 1925 imports of industrial chemicals showed a gain of 25 per cent. and exports a gain of 4 per cent. for the corresponding period in 1924. Although the percentage gain of exports was low compared with imports, the value of the former was over $18,800,000 compared with $2,500,000 for imports.

PHYSICS AND THE ATOMIC STRUCTURE

By E. H. Kennard
Assistant Professor of Physics, Cornell University

Fields.—In Physics a large amount of material has been published by over three thousand investigators. At least one discovery of first-rate importance would seem to have been made: a radically new indication as to the nature of radiation is furnished by the work described below upon X-ray scattering and recoil electrons. Most of the work in physics, however, consists in collecting further data or attempting to improve physical theory at some point. This statement is especially true of work in Heat and in the older parts of Light and of Electricity and Magnetism. In Mechanics the most novel work has to do with special cases in the flow of fluids, which is a subject by no means fully understood even today. On the other hand, in connection with the electrical properties of gases, and in Spectroscopy of all kinds, from the infra-red through the ultra-violet to X-rays and γ-rays, activity is keen and fundamental advances are being made. Out of this mass of results we shall select for discussion a few items that seem to be either particularly significant or of general interest; any one desiring a closer survey of the developments of the year will find it in recent numbers of *Science Abstracts*, Section A.

High-Vacuum Technique. — In using mercury-vapor pumps it is necessary in some way to prevent the mercury vapor from diffusing back into the vessel that is being evacuated. Instead of a trap immersed in liquid air, A. L. L. Hughes and F. E. Poindexter at Washington University recommend the use of a trap at room temperature, containing a gram or so of potassium, which absorbs mercury vapor very readily. They show that in a mass of gas that has passed through such a trap the pressure of the residual mercury vapor is not over a few billionths of a mm. (*Phil. Mag.*, Vol. 50, p. 423).

Relativity.—In this field there have been three interesting experimental developments.

According to the General Theory of Relativity, near a large mass of matter like a star all atomic processes ought to proceed at a slightly lower rate than elsewhere, so that spectral lines ought to be slightly displaced toward the red. At the surface of the sun the shift is small, and the evidence is still somewhat conflicting. According to recent astrophysical speculation, however, there is a class of stars, known as dwarfs with early-type spectra, which are supposed to consist of matter in a state of enormous density and which are, therefore, of abnormally small radius. At the surface of such a star the Einstein shift should be much larger.

Eddington called attention to the companion of Sirius as a suitable star of this type. W. S. Adams (*Nat. Acad. Sci. Proc.*, Vol. 11, p. 382) finally succeeded in getting the light of this star into the slit of a spectrometer placed in the focus of the hundred-inch reflector at Mount Wilson, without admitting too much scattered light from Sirius, which was ten thousand times brighter and only 10″ of arc distant; a shift of the spectral lines toward the red of 0.21 to 0.23 angstrom was observed. The astrophysical theory suggests a specific gravity for this star of something like 30,000 to 60,000 and an Einstein shift at its surface of 0.23 to 0.32 angstrom. This result is taken to lend support both to the theory of stellar constitution and to the General Theory of Relativity.

In the second place, observations have been made by A. A. Michelson and H. G. Gale (*Nature*, Vol. 115, p. 566) which amount to an optical measurement of the earth's rotation on its axis. Their result is consistent with Relativity, but exactly the same shift is predicted by the stagnant-ether theory of H. A. Lorentz.

On the other hand, D. C. Miller, who has been repeating the Michelson-Morley experiment on Mount Wilson, reports observations taken in April that point toward an ether-drift at that time of something like 5 miles per second along a northwest-southeast line (*Nat. Acad. Sci.*, Vol. 11, p. 306). The results agree fairly well with those obtained in April, 1921, although the interferometer has been rebuilt in details and the location on Mount Wilson is different. The same apparatus at Cleveland showed a somewhat smaller drift in the same direction. Such a result, if confirmed, would completely destroy the Special Theory of Relativity.

Sound.—There is little activity in this field; but one item seems to be of sufficient interest to be noted. It is known that sounds of long wave-length (4 ft. and up, or a pitch below middle C) are not much absorbed by smoke or fog, whereas sound waves under a twentieth of an inch long are strongly absorbed even by pure air. Experiments have now shown that sound waves of intermediate wave-length are strongly absorbed by smoke (Altberg and Holtzmann, *Physik, Z.*, Vol. 26, p. 149). For instance, a foot of tobacco smoke, so dense that a light cannot be seen through it, will absorb 30% of the energy of sound waves as they pass through it when the waves are two inches long (corresponding to a pitch of four and a half octaves above middle C).

Magnetism.—The most interesting results in magnetism have to do with nickel and its alloys. It has been found that the Barkhausen effect can be observed in a nickel wire without an amplifier such as is required for iron: when the nickel is gradually magnetized, sharp sounds are heard in a telephone connected to a coil surrounding the wire, due to abrupt changes of magnetization (*Forrer, C. R.*, Vol. 180, p. 1253). Alloys with iron containing 60-85% of nickel, called permalloy, are remarkable for their initial permeability; this is increased by stretching if the per cent. of nickel is less than about 81% but is decreased if the per cent. exceeds this value. When a tension of 3560 lb. per square inch is applied to permalloy containing 75.5 per cent. of nickel, its initial permeability is raised from about 7500 to many times this, reaching the enormous maximum value of 280,000 at a field-strength of 0.025 gauss; saturation is reached for a field-strength of less than 2 gauss, but the saturation value of the induction is no greater than it is in the absence of tension. The application of this tension also cuts in two the hysteresis loss, which is already only a twentieth as great as in soft iron. (Buckley and McKeehan, *Phys. Rev.*, Vol. 26, p. 261).

Spectroscopy.—In this field a large amount of work has been done, both experimental and theoretical, and much definite progress has been made, but nothing is characterized by striking novelty. The experimental work consists largely of the observation of new spectral lines, their fine-structure, and the conditions affecting their intensity. In theory progress has been made especially in the direction of fitting more known lines into spectral series and of explaining these series and other spectroscopic facts in terms of quantum numbers. The following examples are typical of much of the work.

Interesting observations are recorded by I. S. Bowen and R. A. Millikan on the spectra of hot sparks in which "stripped" atoms occur, that is, atoms which have lost all but one of their valence electrons (*Nat. Acad. Sci.*, Vol. 11, p. 329; *Phys. Rev.* 25, p. 591, 600; 26, p. 150, 310). Stripped atoms of elements lying on the same line in the periodic table are found to emit similar spectra, except that the wave-length of the lines diminishes with increasing atomic number. Such a group is formed by sodium in its natural condition, Mg_2 or magnesium minus one electron, Al_3 or aluminum minus two, and so on through Si_4, P_5, and S_6 to Cl_7, which is chlorine minus six electrons. These atoms all consist of an inner core of ten electrons like neon and a single outer valence electron which radiates by dropping from an outer orbit to an inner one; but the nuclear charge varies from atom to atom in proportion to the atomic number. Each of these atoms emits, for one thing, a doublet, that of sodium being the well-known D-lines at 5893 A.; the corresponding doublet for Mg_2 is in the ultra-violet at 2800 A, for P_5 at 1123, and for Cl_7 at 807. Some of the same laws were found to hold for these spectra as hold for X-rays; for instance, the square root of the frequency plotted against atomic number gives a fair approximation to a straight line (Moseley's Law).

Certain lines were identified as due to atoms carrying two or three valence electrons. Several others of short wave-length, such as a line at 724 A. given out by Cl_6, were ascribed to the simultaneous jumping of two electrons.

Resonance Radiation and Fluorescence.—Another trend in present investigation is well illustrated by the interesting observations made on the resonance radiation and fluorescence of mercury vapor by R. W. Wood of Johns Hopkins (*Roy. Soc. Proc.*, Vol. 106, p. 679). When cold mercury vapor is illuminated by ultra-violet radiation of wave-length 2536 A. from a water-cooled quartz mercury lamp, the vapor emits both resonance radiation of the same wave-length and fluorescent radiation of other wave lengths, but the emission of these other lines stops if the 2536 radiation from the lamp is screened off by glass. The accepted explanation is that the 2536 radiation raises the electrons from the normal 1S orbit to the $2p_2$ orbit; radiation of other wave-lengths that are not absorbed by the unexcited vapor can then be absorbed by these excited atoms and can thereby raise electrons to still higher orbits, from which they can subsequently fall back and cause the emission of other lines. This explanation was confirmed by Wood by interposing various absorbing screens in the paths of the exciting rays and noting the effect on the fluorescence. For instance, if bromine vapor is interposed, which transmits only the 2536 line and a few others near it, then the green arc line at 5461 is not emitted; but if the mercury vapor is now illuminated also by another beam of light from a second mercury lamp placed behind a sheet of dense blue cobalt glass, then the mercury vapor emits the green line. In this case the 2536 radiation from the first arc raises the electrons to the $2p_2$ orbit and then the violet 4358 radiation from the second arc raises them from here to the 2S orbit, from which they can subsequently fall into the $2p_1$ orbit and thereby cause the emission of the green line at 5461.

Wood found also that the admixture of a little damp nitrogen with the mercury vapor increased the intensity of the green line and several other lines in the fluorescence as much as ten or twenty times. The nitrogen molecules are supposed to make "collisions of the second kind" with the excited mercury atoms which have their electrons in the $2p_2$ orbit; in doing this they remove a little of the energy of these atoms and lower the electron to the $2p_3$ orbit. From this orbit the electron can then be elevated, by absorption of the violet 4046 line coming from the second lamp, into the 2S orbit, which forms the starting point for the emission of the green line and several others. In confirmation of this explanation Wood showed that, while the mercury vapor mixed with nitrogen was fluorescing, the absorption in it for light of the 4046 wave-length was enormously greater than the absorption of the same line either in fluorescing pure mercury vapor or in the mixture of mercury and nitrogen when this was not being excited. This result shows that the nitrogen has the effect of increasing greatly the number of atoms in the $2p_3$ state, which are the only atoms that can absorb the 4046 radiation.

Near Infra-Red.—A field in which rapid experimental progress may be expected in the immediate future is that of the near infra-red. Work in this region will be greatly facilitated by the discovery in the laboratories of the Eastman Kodak Co. that the use of "neocyanine" as a sensitizer makes a photographic plate sensitive to infra-red light out to 1.1 micron, with a maximum sensitiveness at 0.83 micron.

Aurora Borealis.—J. C. McLennan and G. M. Shrum at Toronto find that the green line at 5577 A which is so prominent in the spectrum of the aurora borealis is readily obtained from helium containing a little oxygen. Many other auroral lines are already known to be emitted by a discharge through nitrogen containing helium, and there is good reason to think that the atmosphere at great heights consists largely of helium; thus the source of the auroral spectrum has, perhaps, been definitely determined, although the exciting cause of the emission is still in doubt. (*Roy. Soc. Proc.*, Vol. 108, p. 501.)

Conduction and Ionization in Gases.—Knowledge of these phenomena is slowly becoming broader and more definite. H. D. Smythe at Princeton concludes from experiments by the method of positive ray analysis that the immediate ionizing effect upon hydrogen of electrons with a speed ranging from the necessary minimum of 16 volts up to 30 volts is the removal of an electron from a hydrogen molecule, leaving the latter positively charged. At very low pressures (0.0007 mm. of Hg) no other kind of ion is formed. At higher pressures (e.g. 0.05 mm.), however, singly positively charged atoms and triatomic molecules occur abundantly, the former being produced probably by the simple break-up of the positive diatomic ions in collisions with other molecules.

Interesting observations on the glow discharge are reported by K. T. Compton, L. A. Turner and W. H. McCurdy at Princeton (*Phys. Rev.*, Vol. 24, p. 597, and 25, p. 606). They introduce the novel idea that cumulative ionization plays an important part here, atoms being first excited by an impact of one electron and then ionized by a second. In this way electrons each having energy much less than the ionizing potential can by their combined action produce ionization. If the current through the tube is strong, ions are abundant and tend to become uniformly distributed by diffusion; under these conditions the positive column is uniform throughout. If, however, the current is weak and the ions are not sufficiently numerous, then diffusion is ineffective, and the positive column tends to break up into "striations" or regions of strong ionization but weak field separated by interspaces in which the ionization is relatively weak while the field is strong. In the interspaces electrons acquire sufficient energy to excite atoms upon arriving at the next striation on their way toward the anode; these excited atoms may then be ionized by other slowly moving electrons.

This interpretation of the phenomena was tested experimentally in the case of the discharge through mercury vapor. The difference of potential between striations was shown to be about 5 volts, which is just above the lowest excitation potential of 4.9 volts, but much below the ionization potential of 10.4 volts. The striations were shown to absorb strongly certain lines in the mercury arc spectrum which are absorbed by excited atoms of mercury but not by atoms in their normal state. Admixture of hydrogen caused the occurrence of striations at higher-current densities, presumably because excited mercury atoms, colliding with hydrogen molecules, spent their energy of excitation in breaking the hydrogen molecules up into atoms and thus returned to the normal state; hydrogen atoms thus produced were detected by a reducing action of the gas in the striations on tungsten oxide. Helium, which cannot be thus acted upon by the mercury atoms, had no effect on the striations.

Very interesting observations were also made by K. T. Compton and C. Eckart at Princeton on a type of non-oscillatory low-voltage arc in argon, with a hot-filament cathode. The voltage drop between electrodes in this arc was only 3 to 6 volts, whereas the lowest "critical" or excitation potential of argon is 11.5 volts, so that the production of enough ions to maintain the arc was hard to understand. Investigation with the Langmuir probe showed, however, that the cathode drop was always very near to 11.5 volts, the current of nearly an ampere actually flowing against an opposing drop of 5-8 volts from a point near the cathode to the anode. It was found that the electron density near the cathode was 20 to 100 times greater than at the anode, and it is believed that the resulting tendency of the electrons to diffuse toward regions of lower densities was the means of maintaining the flow of current through the opposing field. (*Phys. Rev.*, Vol. 25, p. 139; cf. also F. H. Newman, *Phil. Mag.*, Vol. 49, p 1057).

X-rays.—The gap between the ordinary ultra-violet and ordinary X-rays is a field that largely remains to be explored and is being attacked. Very soft X-rays were studied by J. A. Becker at the California Institute of Technology (*Phys. Rev.*, Vol. 24, p. 478) by allowing them to eject photoelectrons or secondary cathode rays from a "radiator" and measuring the speed of these rays magnetically, as was done by Thibaud for γ-rays (See under Radioactivity, below). The energy of the primary cathode rays was varied from 150 to 1500 volts, so that the minimum wave-length of the X-rays varied from 8 to 82 A. Always a strong line was found on the plate due to photo-electrons with speed equal to the primary electrons. This leads to the double conclusion that the photo-electrons were derived largely from the free electrons in the emitting metal, and that the spectrum of the X-rays must have had a very narrow sharp peak at a frequency corresponding to the Einstein equation $h\nu = eV$. Other lines representing smaller speeds were ascribed to photo-electrons ejected from the interior of the atom; for instance, aluminum gave out photo-electrons that were believed to come from the L levels.

When the target which was the source of the X-rays in these experiments became accidentally covered with tungsten oxide, photo-electrons were emitted from the radiator with speeds corresponding to several characteristic wave-lengths for tungsten as calculated from ordinary X-ray series terms. A similar series of critical potentials for iron is reported by C. H. Thomas (*Phys. Rev.*, Vol. 25, p. 322). He allowed the X-rays from an iron target to produce photo-electric emission from platinum; as the voltage on the target was raised in small steps, the photo-electric emission increased, and whenever the voltage passed a critical potential for iron the rate of increase suddenly became greater, presumably due to the emission of a new wave-length not excited at lower voltages. The 32 critical potentials thus found ranged from 3.3 to 818 volts, the corresponding wave-lengths from 1694 to 15 A.

Soft X-rays seem also to be emitted copiously from gas that is emitting the negative glow in a discharge tube (J. J. Thomson, *Phil. Mag.*, Vol. 49, p. 761). The most penetrating part of the radiation corresponds as required by the Einstein equation to the voltage across the tube, and will penetrate readily through a celluloid window 10^{-4} cm. thick when this voltage is several thousand volts, the wave-length of the radiation being therefore several angstroms; but most of the radiation is absorbed by a few centimeters of gas at a pressure of only 0.01 mm. of mercury.

The most important results of the year in the X-ray field, or for that matter in the whole field of physics, are probably some observations on the recoil electrons that are associated with the scattering of X-rays. It has been shown by A. H. Compton (Chicago) and recently confirmed by Ross and Webster (*Nat. Acad. Sci.*, Vol. 11, pp. 56, 61, 224; *Jour. Opt. Soc.*, Vol. 11, p. 217) that part of the X-rays scattered from carbon are of slightly longer wave-length than the incident rays; this has come to be known as the "Compton effect." Such a change of wave-length is hard to understand if one supposes the X-rays to consist of extended waves; but it is completely accounted for by a theory put forward by P. Debye (*Physik. Z.*, Vol. 24, p. 161) and independently by A. H. Compton (*Phys. Rev.*, Vol. 21, p. 483) in terms of Einstein's assumption that the energy of all radiation is concentrated in quanta or minute specks moving with the speed of light like little bullets.

Debye and Compton suppose that when one of these X-ray quanta strikes an electron in a piece of carbon, either of two things may happen. In the first place, the quantum may perish; in this case all of its energy passes over to the electron, which then sets out at high speed as a photo-electron. Or, on the other hand, the quantum and the electron may rebound like two billiard-balls; the quantum then goes off in a new direction as a quantum of scattered X-rays, while the electron flies off as a "recoil electron." The rebound of the quantum may occur in any direction, according to the exact way in which it strikes the electron; but for every direction of rebound of the quantum there is a definite direction and speed for the recoil electron and these can be calculated by applying the usual laws of conservation of momentum and of energy.

The energy of the scattered quantum will clearly be less than that of the incident one because of the energy lost to the recoil electron. The energy of a quantum, however, is supposed to be always equal to $h\nu$, where h is

Planck's constant and ν is the vibration frequency of the radiation of which the quantum is a part. It follows that the frequency of the quantum after scattering will be lower and its wave-length longer than before scattering. The theoretical change of wave-length thus calculated agrees exactly with that observed experimentally in the "Compton effect."

Two other requirements of this theory have now been definitely established by experiment. According to the theory the scattered radiation comes off in spurts simultaneous with the ejection of a recoil electron; and such a coördination in time seems actually to have been detected by Bothe and Geiger (*Zeitschrift für Physik,* Vol. 32, p. 639). X-rays scattered from hydrogen were detected by means of their photo-electric effect. It was found that the production of such a photo-electron was often accompanied by the emission of a recoil electron at the same moment (or at least within the same ten-thousandth of a second), and such coincidences occurred eleven times oftener than they would have done if the scattering of X-rays and the production of recoil electrons had been processes independent in time of each other.

Again, according to the quantum theory there should also be coördination in space between the paths of the scattered X-rays and the points of ejection of the recoil electrons. To test this conclusion, A. H. Compton passed X-rays through a Wilson cloud-expansion apparatus (*Phys. Rev.*, Vol. 26, p. 289) and took stereoscopic photographs showing the tracks of the recoil electrons produced by the main beam along its narrow path and the tracks of the photo-electrons occasionally liberated in the surrounding air by X-rays which had been scattered from the main beam by the air. Out of 850 plates obtained, 38 showed on each a photo-electron track and also from one to three recoil electron tracks. On these plates the angle between the incident beam and the initial direction of the recoil track was measured; also that between the incident beam and a line drawn from the recoil track to the photo-electron track. In 18 cases these angles agreed within 20° with the requirements of the Debye-Compton theory. The chance of obtaining so many cases agreeing thus closely with the theory was estimated as only 1 in 250.

Such results seem definitely to contradict the wave-theory of X-rays; for if the scattered rays spread out in spherical waves, producing photo-electrons here and there as they go, there can be no spatial correlation whatever between the two kinds of tracks. A remarkable contrast to this is afforded by the fact that when the change of wave-length undergone by these same scattered rays is determined, it is done experimentally by reflecting them from a crystal, and the action of the crystal in forming a spectrum seems to be intelligible only if the scattered rays consist of waves. Thus the theory of radiation seems in 1925 to have arrived at an impasse for which there is probably no parallel in the whole history of physical theory.

Radioactivity.—Gamma rays spectra have been successfully explored by allowing the γ rays to impinge upon a "secondary radiator" and to eject therefrom secondary β rays, which were then deflected in a magnetic field onto a photographic plate; from the position of impact on the plate and the constants of the apparatus the energy of the β rays could be calculated (J. Thibaud, *Journ. de Physique*, Vol. 6, p. 82). The β ray spectra thus obtained consisted chiefly of narrow lines, indicating that these rays consist of a number of groups each characterized by a certain energy and speed. This result was interpreted to mean that the spectrum of the original γ rays consisted chiefly of monochromatic lines of frequency ν related to the energy E of the β rays in accordance with the Einstein equation

$$E = h\nu - W,$$

where h = Planck's constant, W = work done by an electron in getting out of an atom. When the same source of γ rays was used in turn with different secondary radiators, the β ray lines varied in position as they should do according to this equation when the known ionization energies for hard X-rays are substituted for W. Some 15 lines, of very irregular intensity, were thus detected in the γ ray spectrum from radium, the β ray energy varying from 233 to 1760 Kilovolts and the γ ray wavelength, calculated from the Einstein equation, varying from .05 to .007 A. Most of these lines correspond closely to the observed speeds of the natural β rays from radium, which supports the view that the latter are simply a photo-electric emission excited from the radium by its own γ rays.

Some observations by Blackett (*Nature,* Vol. 115, p. 493) at Cambridge are also interesting. He photographed, in two perpendicular directions, the tracks of 400,000 α particles in nitrogen. Besides a number of elastic collisions of the α particle with a nitrogen nucleus, eight cases of inelastic impact were found; these are ascribed to the ejection of a proton or hydrogen nucleus from the nitrogen nucleus. The fine track of the proton was clearly visible, also that of the recoiling nitrogen atom, but there was no trace of a third track. From this and other circumstances it was inferred that the α particle was simply captured and held by the nitrogen nucleus; such a capture would leave this nucleus with a mass of 17 and a charge of 8 units, so that it would be an isotope of oxygen.

Atomic Structure.—A. Sommerfeld has declared himself in favor of E. S. Stoner's modification of Bohr's scheme of structure for the more complicated atoms (*Physik. Z.*, Vol. 25, p. 70; Stoner, *Phil. Mag.*, Vol. 48, p. 719 and Vol. 49, p. 1289). Basing the argument upon the evidence of X-ray spectra, Stoner divides the L shell or level into three sub-levels, instead of two, the M shell into five, etc. Then he assumes the statistical weights of the X-ray terms, as found from the relative intensity of the X-ray spectral lines, to be proportional to the numbers of electrons in the various sub-levels. Accordingly the three L sub-levels contain, respectively, when filled, 2(Be), 2(C), and 4(Ne) electrons, as against the 4 + 4 electrons in the L shell according to Bohr.

Stoner's idea of the order of filling in of the sub-levels is particularly simple, there being none of the subsequent rearrangements postulated by Bohr. As we proceed through the periodic table from any one noble gas to the next, the first two electrons are added in a fresh outer shell, then one or more groups of electrons may be added in inner shells, taken in order, and finally two and four electrons respectively are added in two other sub-levels of the outer shell; the resulting completion of the first octet in the outermost shell gives us the next noble gas. The rare earths represent the filling up with fourteen electrons of the sixth and seventh sub-levels of the N shell; no other shell has so many levels occupied in existing atoms.

The new arrangement explains a number of facts connected with optical and X-ray spectra without disturbing the chemical successes of Bohr's scheme. It also fits in well with certain features in the magnetic behavior of atoms if we assume that, when an odd number of sub-levels has been completed in any shell, then the corresponding orbits possess a symmetry such that their magnetic moments cancel each other on the whole. If all occupied shells are in this condition of symmetry the atom as a whole will possess no resultant moment and must be diamagnetic. Thus the noble gases and the vapors of Zn, Cd and Hg are diamagnetic, and observations by Gerlach and Stern on the passage of atoms of the latter three elements through a magnetic field show them to have no magnetic moment. Ionized K and singly ionized Cu also have zero magnetic moment. Silver, gold and neutral copper atoms were found by Gerlach and Stern to have a moment equal to one Bohr magneton, in harmony with the theory.

As another purely theoretical contribution to atomic theory we may notice the new results on the scattering of light by an atom reported by Kramers and Heisenberg (*Zeitschrift für Physik,* Vol. 31, p. 681). They regard the atom as a "multiple periodic" system of electrons whose motions are not simple harmonic but can be represented by a Fourier series of simple-harmonic terms. When a train of simple-harmonic waves of a definite frequency falls upon such an atom it excites, according to classical theory, vibrations which, when resolved by Fourier Analysis, contain the frequency of the incident waves and also the frequencies obtained by adding to this or subtracting from it the sum or difference of any two frequencies occurring in the natural motion of the atom. All of these vibrational frequencies would then, according to classical theory, appear in the light emitted by the atom; the light of the same frequency as the incident light would constitute the ordinary resonance radiation, while that of other frequencies would represent a sort of fluorescence. These facts are then translated into results to be expected on the quantum theory, by means of Bohr's correspondence principle; but the exact bearing on experimental results is not known at the present time.

Further results on isotopes have been announced by Aston (*Phil. Mag.* Vol. 49, p. 1191; *Nature*, Vol. 116, p 208): bismuth, the heaviest atom yet analyzed, with atomic weight 208.0 contains only one isotope; iron, of atomic weight 55.84, contains atoms of weight 54 as well as 56; mercury atomic weight 200.6, contains isotopes with weights 198, 199, 200, 201, 202 204. An isotope effect on band spectra is reported by R. S. Mulliken (*Phys. Rev.*, Vol. 26, p. 1), who found that the bands emitted by cuprous iodide are double; the stronger set comes from molecules containing a copper atom of weight 63 and the weaker from molecules containing the other isotope of copper of weight 65

ORGANIC EVOLUTION

By H. S. Jennings
Professor at Johns Hopkins University

The present time sees in progress a notable advance in the understanding of the nature and origin of mutations and "what are called species" and through this, possibly, of some of the major factors in evolution. The nature of this advance may be set forth as follows.

Evolution and Chromosomal Changes.—The way in which an organism develops and the characteristics it produces are known to depend, in large measure, on the stock of substances present in its chromosomes; these, by interaction with each other and with other things, produce the developed organism. Altering any of these substances alters the characteristics produced. Any such alteration that is handed on to new generations results in new inherited characteristics, in a "mutation," a new "elementary species." Evolutionary change lies essentially in the permanent alteration of the chromosomal substances.

Certain methods by which these substances are altered are coming to light. An individual at the beginning is formed by the union of two germ cells, and each of the two germ cells contains a single "set" of chromosomes—of definite constitution and number. The individual so produced thus contains two such sets; its chromosomes are in pairs. In development all the chromosomes divide at each cell division, so that all the cells of the typical individual contain the two sets. Alternations of the chromosomal outfit are found to occur as follows:—

1. **Divisions.**—Sometimes the chromosomes divide and thus double, without cell division. This may happen in the fertilized egg, so that it now contains four sets in place of two. Thereafter cell divisions coincide with chromosomal divisions, so that an individual is produced with four sets of chromosomes in its cells. Such individuals are larger, with larger cells and organs, and may differ in structure from the parent stock, with but two sets. They now propagate themselves in the usual way, so that a mutation or new race is produced. One of the well known mutations of Oenothera is of this nature, and races with four sets of chromosomes are known for several organisms.

2. **Three Sets.**—These individuals with four sets produce germ cells with two sets; such a germ cell may unite with one containing but a single set, thus producing an individual with three sets. These differ both from those with two sets and those with four sets. The odd number of sets of chromosomes causes disturbances in the usual method of reproduction by union of two germ cells, but such individuals with three sets at times reproduce from a single germ cell, yielding thus a permanently diverse race.

3. **Classes.**—Irregularities in germ cells in races with three sets of chromosomes give rise to numerous different classes of germ cells, with diverse combinations of chromosomes. Some of these on union with other germ cells can develop; they thus give rise to hereditarily diverse races.

4. Single Germ Cells.—In producing germ cells, the two chromosomes of a single pair normally separate into different germ cells. Failing to separate, they may pass together into a single germ cell, while a corresponding germ cell is produced entirely lacking any representative of this pair. Thus some of the germ cells have one more chromosome than normal (that is, $n+1$); others one less ($n-1$). Such germ cells may now unite with another having either n, $n+1$, or $n-1$ chromosomes, giving rise to individuals of various diverse numbers of chromosomes. Such individuals differ among themselves in their hereditary characteristics; they are known in Oenothera and many other organisms.

As the different chromosome pairs differ in their effects on development, diverse results are produced in different cases, depending upon which chromosome pair thus has two representatives, or none, in the individuals produced. The occurrence of this kind of change ("non-disjunction" of the chromosomes) has been observed in a number of species.

5. Hybrids may be produced by intercrossing of stocks having different numbers and combinations of chromosomal materials, with new or irregular numbers of chromosomes. Some of the chromosomes from the two parents are at times incompatible; so that these alter or destroy one another; while others work together readily. Thus a great variety of individuals, with varied combinations of chromosomal materials, are produced. Some of these cannot reproduce and are eliminated. Others do reproduce, giving rise to diverse stocks ("mutations," "elementary species," and the like). By combinations of these and other methods, and by intercrossing among the stocks so produced, a great variety of diverse stocks results. Phenomena similar to or identical with the "mutations" in Oenothera, in Drosophila, and in other organisms occur in such cases; the sporadic appearance of new types, some of which reproduce themselves, while others do not, or do so but scantily. Natural selection on a large scale operates in these new stocks, many being at once eliminated, while others persist.

Observations.—These processes and results observed both in breeding work and under the microscope, in many organisms. A description of many of these cases, with discussions of their relation to the origin of mutations and of species, by a number of investigators, will be found in the *American Naturalist* for May-June, 1925 (1); accounts of them are given also by Gates (2), Lotsy (3), Jeffrey and Hicks (4), Boedijn (5), Hurst (6) and others.

Many of the species described by the systematist are found to differ in their chromosome numbers in exactly such ways as would result from the processes outlined above. Thus in wild roses, the number of chromosomes in a set is 7; some species have 2 sets; others 3 sets, others 4, others 5, others 6, others 8, and similar conditions are found in other plants [see (1), (2), (6)].

The Relation to Evolution, particularly of the changes resulting from hybridization, to the evolutionary process, is judged somewhat differently by diverse investigators. Practically all agree that many of the diverse organisms that in taxonomy are called species are produced in this way; it is at least one method of "the origin of species." Lotsy (3) holds the production of such changes by hybridization to be the chief method of evolution. Jeffrey (7), on the other hand, holding the "mutations" of Drosophila to be of this type, argues that they therefore do not exemplify evolutionary change. On the whole it appears probable that changes of this kind play a great rôle in producing the lasting diversities observed in the organic world. They cannot, however, account for the first diversities that must have appeared before new ones could be produced by interaction of those already present [see Lotsy].

6. Artificial Production of Chromosomal Changes.—Mavor (8) reports that by the action of x-rays on Drosophila certain chromosomal irregularities were produced (of the sort described in paragraph 4 above) and that these resulted in heritable changes. Such work is only in its beginning.

7. Attempts to alter the apparatus of inheritance somewhat less directly, by the action of physical and chemical agents on the developing organism, have continued. The outstanding work is that of Guyer (9). Inherited eye abnormalities were induced in a few cases by injecting ground up lens material into the pregnant mother. Huxley and Carr-Saunders (10), on the other hand, in an attempt to repeat this work on an extensive scale, found it impossible to observe such results.

8. Still more indirect attempts to alter permanently the apparatus of inheritance, so as to yield "the inheritance of acquired characters" have continued. Typically, these consist in the following: by supplying a certain environment, the organism is induced to develop certain characteristics which it would otherwise not have developed; then later generations are tested as to whether they in consequence, even without that environment, produce in some degree these new characteristics. Kammerer (11) has published a book giving the experimental evidence and general arguments for this, based upon his own extensive researches in the matter.

Eldridge's book (12) makes an extensive affirmative argument for the inheritance of acquired characters, while a chapter in Morgan's recent book (13) presents an argument for the negative. A most excellent and impartial brief summary of the state of knowledge on this matter is given by Detlefsen (14).

Production of New Varieties in Nature.—Crampton (15) publishes a continuation of his researches on the Variation, Distribution and Evolution of the Genus Partula in some of the Pacific Islands. "All of the evidence proves that specific and racial diversification of the material under investigation is due to the operation of internal factors and not to external influences" (p. 2). This thus agrees in so far with what is set forth in Section I, above.

Scopes Evolution Trial.—Popular interest in organic evolution was greatly stimulated in 1925 by the Scopes trial, under the Tennessee law forbidding the teaching of evolutionary doctrines in the public schools. There was a consequent great demand for information and elucidation, resulting in many articles in the magazines, and a number of books. A symposium on the Evidences for Evolution, by well known men of science, was published in the *Scientific Monthly* (16) for August, followed in the September issue (17) by the statements on the matter prepared for the Scopes trial by the scientific witnesses for the defense.

Among the books brought out by the great demand for elucidation of the subject are small volumes by Parker (18), Kellogg (19), and Osborn (20); more technical is the volume by Morgan (13). On the other side, More (21) has published a volume criticizing sharply the various doctrines based upon or subsidiary to the general doctrine of evolution; particularly its supposed philosophical and sociological implications.

VERTEBRATE ZOOLOGY

By James Ernest Kindred
Professor at University of Virginia

Morphology.—In view of the recent interest aroused by Krogh, the experimental observations of E. R. and E. L. Clark (*Am. Jour Anat.*, 35, no. 2) on the mechanism of contractility in the capillaries of the tadpole tail are significant. These investigators have patiently watched developmental changes in the transparent tail. They have observed the development of the capillaries by sprouting from other capillaries. The capillaries so formed are embraced by connective tissue cells, comparable to the cells of Rouget. Careful study of the capillaries in experimentally produced capillary contraction shows that the endothelial cells are inherently contractile. The endothelial wall of the capillary was observed to draw away from the Rouget cells. These observations establish definitely the status of the endothelial cell as an independent contractile unit.

Higgins, from a study of the lymphatic system of newborn rats injected with india ink, concludes that a greater number of lymph channels, but fewer lymph nodes, are present at this time as compared with the adult rat.

The microscopical anatomy of the so-called hairs, on the "hairy frog," Astylosternus robustus, shows them to be accessory respiratory organs according to Noble. Noble has found that their development is correlated with a diminution in the respiratory surface of the lungs. Structurally the hairs are reduplications of the integument and their epithelium is penetrated by capillaries. Furthermore, the hairs are found only on the male of this species; capillaries are present in the skin of the corresponding regions of the female, but no hairs occur. Another interesting correlation between the vascular and respiratory systems described in this paper is the coincidence of varying degrees of lunglessness and a reduction of the left auricle of the heart in some amphibia, and in others a fenestration of the interauricular septum. From these facts it would appear that the structural nature of the heart is to some extent dependent upon the manner in which respiration is carried on.

The interest of hematologists has been centered for a long time on the genetic relationships between the several types of blood cells in the vertebrate body. Jordan (*Am. Jour. Anat.*, 35, no. 2), as a result of the reactions of the segregation apparatus of certain of the leucocytes of frog's blood to neutral red staining and the phagocytic reaction of the cells to injections of india ink, infers that a genetic relationship exists between the cells exhibiting these reactions. The segregation apparatus appears in a closely graded series of transitional stages from monocyte to lymphocyte. Such a gradation Jordan interprets as indicative of a genetic relationship between these cells. There is also a gradation of phagocytic response on the part of the leucocytes toward India ink particles. This response is independent of the segregation apparatus. The monocytes are the most active phagocytes, the lymphocytes are slightly phagocytic, while the neutrophils take up only a few fine particles.

Leucoplastids occurring in the blood of urodeles are considered by Emmel to be derived from thrombocytes and basophilic mast cells. Such cytoplasmic elements are believed to be representative of the cytoplasmic fragments (red blood corpuscles and blood-platelets) of mammalian blood.

The bronchial movements of man have been subjected to X-ray photography by Macklin in order to find out the relationships of the bronchial tree during breathing. He finds that the branches of the bronchial tree elongate and dilate on inspiration, and shorten and narrow on expiration. The root of the lungs, together with the lower end of the trachea and bronchi, descends in inspiration and ascends on expiration.

Izawa states that the proportional increase in weight of the pineal body of the albino rat from birth to maturity is less than that of any other organ in the rat. The increase in size of the pineal body is caused by the hypertrophy of the parenchymal cells.

Langworthy, from a morphological study of the panniculus carnosus, finds that in rodents it is closely associated with the pectoral musculature. Branches of the cervical plexus which innervate the pectoral musculature also innervate the panniculus carnosus.

According to Fell the cartilage matrix in the long bones of the chick is formed as a secretion of the chondroblasts and is not an extension of their cytoplasm.

Latimer has followed the comparative increase in weight of the central nervous system of chickens during postnatal development. He finds that the increase in weight of the central nervous system from hatching to maturity is as follows: brain, 4.2 times; mesencephalon, 3.4 times; cerebellum, 4 times; medulla, 4.5 times; prosencephalon, 4.7 times; and spinal cord, 19 times.

Embryology.—During the past year several important contributions have been made to the much debated problem of germ-cell origin and specificity in vertebrates. G. T. Hargitt (*Jour. Morph. and Phys.*, vol. 40, no. 3), from a study of the development of the germ cells in the albino rat, concludes that they arise from the peritoneum in the region of the genital ridge. He says, "The argument for the specific character of the germ cells in vertebrates and their continuity from the egg is based largely upon assumption, and not upon substantial observations and must be discarded. Germ-cell origin is a problem of cellular differentiation, and not of early segregation." As additional evidence for this idea of cellular differentiation we have the results of Davenport's ovariectomy experiments on mice. He removed one or both ovaries from mice and found that in about two-thirds of the cases ovaries were regenerated. Some of the mice with regenerated ovaries became pregnant and the ovaries contained the corpora lutea of pregnancy. From his observations Davenport concludes that ovarian tissue may arise *de novo* from the peritoneum and the new ovaries show evidence of functional activity.

New data on the estrus cycle in the mare are given by Seaborn. He finds that the cycle lasts twenty-four days, divided as follows: rest, 8 days; proestrus, 3 days (period of heat, but will not accept male); estrus, 3 days (in heat and will accept male); metestrus, 10 days. The uterine and ovarian phenomena associated with the phases of the cycle conform with those found in other mammals which have been studied intensively. Seaborn agrees with Edgar Allen that estrus is the product of the follicular fluid and not of the corpus luteum.

L. B. Arey (*Anat. Rec.*, vol. 30) gives the following simple formulæ for estimating the age and size of human embryos:

Standing height (cm.) × 0.2 = Age (months).

Sitting height (cm.) × 0.3 = Age (months). (For embryos less than 10 cm. add one month.)

Age (months ÷ 0.2 = Standing height (cm.).

Age (months) ÷ 0.3 = Sitting height (cm.).

Swenson gives directions for producing cerebral anemia in the rat, which he says are efficacious in the study of fetuses in utero. His method is to ligate the external jugular veins and carotid arteries, thereby producing a physiological condition approximating that of decerebration. After operation the animal is immersed in a bath of warm saline and the living fetuses exposed for study. Favorable conditions obtain for about two hours.

Vogelaar and van de Boogert (*Anat. Rec.*, 30) have shown that it is possible to study the development of the hen's egg in vitro. The shell is removed and the egg floated in a salt solution or a medium made from the albumen of another egg. Development to the end of the fifth day may be studied by this method.

B. M. Patten presents morphological evidence for a valvular mechanism in the single interatrial septum of the heart of the chick embryo. From the positional relationships of a number of foramina in the septum, and the shape of the septum in reconstrutions of diastolic and systolic stages, Patten concludes that these foramina are opened åt diastole by the caval blood which forces its way into the left atrium. At systole the foramina are obliterated by the equalization of pressure in the atria and by the contraction of the interatrial septum itself. These foramina and the adjacent flaps may therefore be interpreted as functioning in a manner comparable to the foramen ovale, the septum primum and the septum secundum of the fetal human heart.

McClure and Butler give a very clear and complete description of the development of the inferior vena cava in man. Their stages comprise very young human embryos, and the important changes in the topographical relationships of the several pairs of primordial cardinal veins are emphasized. The postcardinal veins are not as important in the later stages of fetal development as they are in other mammals, consequently they atrophy early. The supracardinal and subcardinal veins are the most important contributors to the inferior vena cava. The pars hepatica of the inferior vena cava appears very early in development and marks the beginning of the asymmetry which is characteristic of the inferior vena caval system.

Dawson suggests that a small bone, the præclavium, the development of which he traced in the rat, is the homolog of the sternal epiphysis of the human clavicle. His suggestion is supported by the absence of a sternal epiphysis from the rat clavicle, and from the fact that the præclavium which develops in this region of the rat has an ossification history which parallels closely that of the sternal epiphysis in man.

From a study of a large number of specimens of adult and embryo cats, Boyden concludes that pancreatic bladders are derived from pancreatic primordia and not from the gall bladder, cystic duct, or ductus choledochus, as it would seem from their position in relation to the gall bladder. The principal evidence for this view is the fact that the wall of all pancreatic bladders examined is an hypertrophied pancreatic duct, and that the ventral pancreas of cat embryos is of regular occurrence and gives rise to accessory lobes some of which penetrate the loose mesenchyme in the region of the gall bladder.

Cytology.—Chambers and Renyi have made an important contribution to our knowledge of the physical relationship of epithelial cells. By microdissection they have demonstrated the presence of dense protoplasmic bridges between the component cells of stratified squamous epithelium; a slime-like cement between the cells of the transitional epithelium of the bladder; and the fact that the cells of ciliated epithelia are only closely adherent along the borders of their distal ends. They find that gland cells are the most fluid of the epithelial cells which they examined and that the cells of an alveolus of a gland, such as a pancreatic acinus, are held together by a fibrous investment. Furthermore, they have shown that the nuclei of epithelial cells are structureless and fluid, and that the nuclear material coagulates with extreme ease upon mechanical injury.

In the ninth of a series of papers on the nature of mitochondria, Wallin presents evidence from cultures of liver tissue from fetal, newborn, three-week-old and adult rabbits which he thinks demonstrate definitely that mitochondria are of bacterial organism. His conclusions are based on the morphologic identity of mitochondria in degenerating liver cells of the cultured tissues with surface bacterial upgrowths obtained in previous culture experiments.

Wen Chao Ma presents evidence for the origin from mitochondria of the colloid in the follicle cells of the thyroid gland. The cells pass through a definite cycle leading up to the production of colloid. In the early stages the mitochondria show signs of growth and proliferation. In the final stage the mitochondria, in granular form, swell and dissolve in vacuoles of cytoplasmic origin which form the colloid or characteristic stainable secretion of the thyroid gland.

Dolley as a result of a series of observations on the pancreatic tissue of white rats in various stages of induced functioning of the pancreas, concludes that there is a definite morphological and physiological relationship between the nucleus of a secreting pancreatic cell and its secretion. He shows that before zymogen is present, the nuclei are hyperchromatic. Then follows a stage of chromidial formation with a reduction in the chromatic character of the nucleus. Finally zymogen replaces the chromidial formations and the nucleus becomes small and shrunken. Eventually the zymogen escapes from the cell and it is exhausted both as regards nucleus and cytoplasmic content.

Additional information concerning the origin of osteoclasts is presented by H. E. Jordan. Basing his conclusions upon the study of bone marrow of larval and adult frogs whose growth has been affected by treatment with thyroid in the case of the larvæ and by removal of the spleen in the adults, Jordan finds that the osteoclast or giant cell of the bone marrow develops by the fusion of the predominating type of cell present. In the splenectomized adult they arise by the fusion of hemoblasts; in the thyroid-treated larvæ by the fusion of stromal cells. In normal adults, osteoclasts are very rare or absent.

Evidence for the erosive action of the cells of the cytotrophoblast layer of the mammalian placenta is given by Pljesakov. Placental tissue from the rabbits was cultured in vitro. The syncytial layer of the chorion degenerated, but the cells of the cytotrophoblast gave rise to giant cells which invaded the nutritive medium and accumulated fat droplets and other droplets which are thought to be protein in nature. These giant cells are also phagocytic and take up the embryonic and maternal blood cells which are left in the cultures upon the degeneration of the blood vessels. From their activities it is probable that these cells are the active agents in preparing the uterine mucosa for the implantation of the ovum.

W. H. Lewis has observed the engulfment of living blood cells, monocytes and hypertrophied monocytes by similar cells in hanging drop cultures of frog blood. From the relation of the engulfing cells to that which is engulfed, Lewis thinks that the engulfed cells are not taken into the cytoplasm of the engulfing cell. The reason for such engulfment is thought to be dependent upon some pathological condition in the animal at the time the blood was drawn.

Experimental. — The degenerative effect of section of extrinsic nerve fibers of the intestine on the intercellular fibers of the myenteric plexus in cats and dogs has been studied by S. E. Johnson (*Jour. Comp. Neur.*, vol. 38). He finds that the intercellular fibers degenerate upon cutting the extrinsic nerve fibers of the intestine and the vagus nerve. This he concludes is evidence that the intestine is supplied like other viscera with both craniosacral and thoracicolumbar innervation.

Another series of experiments on nerve degeneration has been carried on by W. F. Allen in the cat. The cutting of the mylohyoid branch of the trigeminal nerve produces chromatolysis (degeneration of the nucleus) in practically all of the cells in the motor root; section of the inferior alveolar and the lingualis branches of this nerve produce chromatolysis in connective tissue cells surrounding the motor root. The severance of the masseteric branch of this nerve had, however, no effect on the cells in and around the motor root. The latter effect was to be expected if the proprioceptive sense center for the masseter and temporal muscles lies in the mid-brain as Allen has previously demonstrated.

Detwiler and Lewis have shown that a unilateral excision of the fore-limb of Amblystoma before the nerves have grown into the developing limb is followed by a reduction of the brachial motor nuclei. A greater reduction is brought about by the excision of both fore limbs. According to these investigators these results indicate that the size of the brachial motor neurons is influenced both by the completeness of their functional connection with limb and by reflex connections with the local commisural neurons of the opposite side of the cord.

Hoadley (*Jour. Exp. Zool.*, 42) obtained some interesting results from grafts of embryonic tissues of the chick on to the chorio-allantoic membranes. In one series of experiments he used the somitic region of chicks of 36 to 48 hours' incubation. In these grafts, after they had been allowed to develop, there were found epidermis, spinal ganglia, gut, liver, pancreas, pronephros and mesonephros, striped and involuntary smooth muscle. His most important conclusion is that the somitic region when transplanted alone will differentiate independent of any innervation, a conclusion which is contrary to the hypothesis of formative stimuli of Herbst.

In another series of experiments Hoadley transplanted developing primordia of the somitic region (without the spinal cord) of a chick into the region of the mesencephalon of the same embryo. He found that nerve fibers, which under normal conditions of development, form correlation units in the optic center, grow out from the mesencephalon to the muscular tissue, mesonephric tissue and connective tissues developing from the transplant. Hoadley thinks that this is evidence for a great functional plasticity on the part of the nerve cells, and furthermore, that the factors concerned in the differentiation and growth of the nerve fiber must be of a very general nature, dynamic rather than chemotactic.

Additional evidence of the importance of the continuity of the nerve trunk for the proper functioning of neuroepithelial cells is submitted by Brockelbank (*Jour. Exp. Zool.*, 42). This investigator observes that the lateral-line organs of the catfish degenerate four days after cutting the lateral-line nerve. The lateral-line organs regenerate partially at 54 days and completely at the end of 116 days, presumably upon regeneration of the nerve.

Harrison (*Jour. Exp. Zool.*, 41) in a study of histogenetic changes produced by transplanting the primordium of the balancer of Amblystoma, confirms Baitsell's idea that connective tissue fibrils develop extracellularly. Harrison's experiments also show that the successful growth of a transplanted primordium depends upon several factors chief of which are: (1) similar ages of host and donor; (2) transplantation to a specific region of the body. Transplantation from a species in which a balancer is normally present to a host in which it is normally absent is favorable to the development of the primordium.

B. M. Allen has shown that when either the thyroid gland or the pituitary gland or both are removed from tadpoles limb development ceases. He interprets these findings as indicating a close correlation in function between the thyroid and pituitary glands.

Speidel has continued his studies on experimental hyperthyroidism in the tadpole with observations on the relation of this treatment to bilateral symmetry. He finds that normally in about 70 per cent. of cases, the left forelimb is the first to erupt in metamorphosis. This percentage is raised to 100 in experimental hyperthyroidism. The probable explanation of this phenomenon lies in the reactions of the cells, in the region of the asymmetrically placed spiracle, to the thyroid treatment. These cells evidently degenerate more rapidly than under normal conditions and allow the left limb to erupt with greater ease.

Speidel has interpreted eye-protrusion in thyroid-treated tadpoles as comparable to exophthalmos in man (*Jour. Am. Med. Assoc.*, vol. 83). Exophthalmos in the tadpole is interpreted as caused by an excessive proliferation of the cells in the ora serrata region of the eye.

In a study of the effect of hyperthyroidism on tadpoles' gonads, Speidel has shown that the interstitial cells increase in number. The spermogonia and oögonia are but slightly affected. Speidel suggests that this effect of hyperthyroidism on the interstitial tissue of the gonads is a part of the mechanism by which early maturity in secondary sexual characteristics is attained by hyperthyroid individuals, and conversely why hypothyroid individuals have a retarded maturity.

Liddell has given some interesting data regarding the effects of thyroidectomy in sheep. He has studied the effects on the skull, particularly. An undershot jaw is the most characteristic feature of the experimental animals. Defective development of the teeth, disproportionate relationships of the skull as a whole, and faulty ankylosis of the bones of the cranial base have also been observed.

Swingle and Nicholas (*Am. Jour. Anat.*, vol. 36, no. 1) have shown that autoplastic parathyroid transplantation is successful in cats. Tetany is prevented and the tissue survives. Homoplastic parathyroid transplantation was unsuccessful, and survival was rare, as in most animals the transplant degenerated and the animal died.

According to Warwick the testes of swine do not degenerate upon vasectomy.

R. K. Burns has added substantially to our understanding of the method of the determination of sex by his observations on experimentally joined (parabiotic) twins in Amblystoma. He joined Amblystoma larvæ together in side by side fashion at the time the medullary plate was closing, quite a time before the gonads begin to develop. According to the general distribution of sex in normal larvæ, which is one male to one female, the distribution as regards sex in the parabiotic twins should have been one male, two male-female, one female. But actually the distribution of sex approached the ratio of one male to one female. There were no bi-sexual twins. The significance of this experiment inheres in the fact that an original sex bias was evidently reversed in some cases. Furthermore, it shows that at a certain stage in development animals are plastic as regards sex, and that some agency, probably hormonal in nature, is sufficient to change the hereditary course of development of the hitherto indifferent gonad. No prepotency of either sex was observed. Evidently the "all or none" reaction took place, and the sex-chromosomes or sex-heredity complex was overpowered by the sex-hormone.

Jordan and Speidel, in summing up the effect of splenectomy on erythropoiesis in the frog, find that out of 64 specimens operated upon erythropoiesis was stimulated in the kidney in 35 to 46 per cent., in the fat bodies in 5 per cent., in bone-marrow in 11 per cent., and that no stimulation took place in 24 per cent. of the individuals. New spleens were formed in 8 per cent. of the cases. The life tenure of the frog erythrocyte is estimated at about 100 days.

H. M. Smith has presented some interesting results regarding the correlation between the size of cells in the animal body and the metabolic rate. He worked on amphibia and used the red blood corpuscle as the criterion of cell size, and carbon dioxide production as indicative of metabolic rate. He finds that in those amphibia with larger red blood cells, the metabolic rate is lowest; whereas in those with small red blood cells the metabolic rate is greatest. Therefore, he concludes that there is a direct correlation between the metabolic rate and the size of the cells in the body.

Pearcy and Koppânyi have shown that by dislocating one eye of a goldfish, and at the same time removing the other eye equilibrium of the body is disturbed and a tilting is produced of 45 degrees from the vertical in the direction of the horizontal plane. The reposition of the dislocated eye restores equilibrium immediately. The experimenters think that the tilting of the body is probably due to attempts on the part of the fish to keep its visual field in the horizontal plane, and furthermore, that this compensatory movement is a voluntary action.

By a series of experiments Boschma (*Biol. Bull.*, 48, no. 6) has shown that the change in color of the Javanese lizard, Ptychozoön homalocephalus, is controlled by the eyes. The actual change is caused by the contraction and expansion of the chromatophores in the cutis. Animals in sunlight with eyes covered have the same color as animals in darkness.

Adolph and Collins have been able to increase molting in the amphibian Diemyctylus by several methods. Under normal conditions molting is not very frequent; under laboratory conditions, however, it increases and death is preceded by numerous molts. In molting, a single superficial layer of cells separates from the subjacent cells nearly simultaneously over the surface of the whole body. Experimental induction of molting, by treating either with hot water or by bandaging the body or tail with gauze, is followed by a latent period of from six to ninety-six hours. According to these investigators the primary significance of molting is possibly the attempt to get rid of unautolyzable waste materials, such as wornout epithelial structures.

INVERTEBRATE ZOOLOGY

By Harley J. Van Cleave

Professor at the University of Illinois

Zoology.—Since the close of the Great War, America has assumed an unprecedented position of prominence in the various subsciences of the invertebrate field of Zoology. The literature for the year 1925 includes an especial abundance of references pertaining to Medical Zoology and Parasitology. The subjects of Ecology and Physiology of invertebrates have likewise attracted much attention. Morphology and Development have received relatively less emphasis in research publications than in former years. Some notable contributions to the literature in Systematic and Faunistic Zoology have been included in the year's inventory. In the following paragraphs, only a few outstanding or characteristic papers have been cited under the sundry headings as an index to the paths of progress though many references fully as significant have been omitted.

Medical Zoology and Parasitology.—Interest in the various phases of Medical Zoology and Parasitology has increased so much during the past few years that various journals and programs of scientific societies have accorded unparalleled prominence to these fields. The contributions of L. R. Cleveland at the Washington meeting of the American Association for the Advancement of Science were deemed of such merit that Dr. Cleveland was made the joint recipient of the Association Prize. One of his papers (*Biol. Bull.*, 48:455) records the results of subjecting termites to increased oxygen pressure. The Protozoa living as parasites in the termites were killed at oxygen pressures that did not injure the hosts. This discovery has particular significance in its application to the removal of protozoan parasites from invertebrates and the cold blooded vertebrates.

C. H. Barlow's "Life Cycle of the Human Intestinal Fluke Fasciolopsis Buski," stands as one of the significant contributions of the year (*Amer. Jour. Hygiene*, Monog. Series No. 4). The developmental cycle, experimental infestations, prophylaxis and control measures for Fasciolopsis are treated comprehensively.

Hookworm.—The control of hookworm disease has continued to demand attention. W. W. Cort (Ibid., No. 5, p. 49) has issued the final part (34) of the series of papers embodying the results of the work which he and his associates undertook in studying hookworm disease in Trinidad and Porto Rico. J. H. Sandground (*Jour. Parasitol.*, Vol. 11, p. 140) has recorded the presence of a new human parasite for America in his records of Rhabditis hominis from Virginia and Georgia.

Ecology and Physiology.—Considerable attention is being directed towards the conditions in the environment which control the distribution of forms of life. L. E. Noland (*Ecology,* 6:437) studied sixty-five species of fresh water ciliates in relations to temperature, dissolved oxygen, hydrogen-ion concentration, and amounts of free and fixed carbon dioxide of the water. He found that most species have a wide range of tolerance to variations in the factors studied. Samuel Eddy, in analyzing the distribution of marine Protozoa (Trans. Amer. Micros. Soc., 44:97) offers a classification under the two groups, Pelagic Formation and Beach Formation. B. H. Willier, L. H. Hyman, and S. A. Rifenburgh (*Jour. Morph. and Physiol.,* 40:299-340) have given a detailed study of the intracellular digestion in a flatworm, emphasizing the histochemical processes in their study of digestion in Planaria dorotocephala.

Organic Polarity.—E. J. Lund (*Jour. Exp. Zool.,* 41: 155) has investigated the experimental control of organic polarity by electrical current. He found that living tissue of Obelia produces a continuous output of electrical energy as distinct from the discontinuous character of the electrical energy produced by nerves and muscles. The cells possess an electrical polarity associated with their structural and functional polarity.

Morphology and Development.—Aside from the studies upon Protozoa and some of the worms, there have been few contributions dealing with the details of Morphology. Miss Hyman (Trans. *Amer. Micros. Soc.,* 44: 51) has given additional data on the morphology, especially of the reproductive system, of Planaria dorotocephala. Only recently have students of fresh water molluscs paid particular attention to characters other than those of the shell. A recent paper by H. B. Baker (*Proc. Calif. Acad. Sci.,* 14:143) gives a detailed account of the organization of a peculiar limpet-like Lymnæid snail from the West Coast.

The Morphology and Reproduction in the Protozoa have been given especial attention. L. L. Woodruff (*Amer. Nat.,* 59:225) has summarized recent advances in our knowledge of reproduction in this group and has concluded that the sexual cycle is neither universal nor even of as frequent occurrence as has been believed in the past. As a result of his studies on the significance of conjugation and endomixis in Infusoria, he concludes that a sexual reproduction is adequate for members of this group.

Caswell Grave and F. O. Schmitt (*Jour. Morph. and Physiol.,* 40:479-515) have studied the mechanism for coördination and regulation of movement of cilia. In the fiber-like structures within ciliated cells of molluscs they see a suggestion of conduction paths for stimuli. E. M. Landis (*ibid.,* 40:111-167) has found that conjugation in Paramecium multimicronucleata is, in its gross features, similar to that of Paramecium caudatum. He further found that the potentiality for the formation of extra vacuoles in Paramecium is a specific character of P. multimicronucleata. Walter N. Hess (*ibid.,* 40:235-259 and 41:63-93) has given a detailed account of the nervous system in one of the commonest laboratory animals, the earthworm, Lumbricus terrestris. In the second of these papers he has given contributions to the morphology and distribution of the light receiving cells.

Select References.—A group of papers from the Zoological Laboratory of the University of California has recently appeared giving the results of numerous investigations on problems in the Morphology and Development of Protozoa (*U. of Calif. Pubs. in Zool.*, 28, Nos. 1-5). David Causey has directed attention to the mitochondria in Endamoeba gingivalis and in Leishmania brasiliensis. R. P. Hall has made a study of mitosis and nuclear phenomena in Ceratium. Beatrice F. Howitt has given attention to the cultivation of Endamœba gingivalis.

Abnormal individuals at times furnish clues to the understanding of some of the factors and conditions concerned in development. F. Smith (*Trans. Amer. Micros. Soc.*, 44:90) has assembled the data upon abnormal specimens of an earthworm (Helodrilus subrubicundus) in his collections. C. L. Turner (*Biol. Bull.*, 48: 225) has added still further to the analysis of abnormal secondary sexual characters in crayfishes and finds that species differ greatly in their tendencies toward the production of supernumerary secondary sexual characteristics.

Systematic and Faunistic.—The literature of Systematic Zoology has been enriched by the addition of numerous shorter papers dealing with specific descriptions. Many species, formerly unknown, have been added to the ever increasing list of the known animal forms. Especially among the worms and the Protozoa are we confronted with a measure of the imperfection of our knowledge of the forms of life. One of the outstanding contributions toward our knowledge of the classification of the invertebrates is the monograph by Mary J. Rathbun on "The Spider Crabs of America" (*U. S. Natl. Mus. Bull.*, 129). Further works on the Crustacea include C. D. Marsh's recent key to the genera of fresh water copepods belonging to the family Centropagidæ (*Proc. U. S. Natl. Mus.*, 64: Art. 8) and G. S. Dodd's "Entomostraca from Colorado" (ibid., 65: art. 18). The seventeenth paper by C. B. Wilson on the parasitic copepods in the National Museum (ibid., 64: art. 17) presents further data upon the fishes which serve these parasites as hosts and upon the naming of the parasites.

Molluscs.—The papers dealing with new species of Molluscs are beyond enumeration in this article. Many of the types of molluscs in the collections of the U. S. National Museum were never figured until the recent contribution of Wm. H. Dall (*Proc U. S. Natl. Mus.*, 66: art. 17). The *Midland Naturalist* (9:321) carries an article by A. E. Ortmann on the mussel fauna of the Muscle Shoals region. With the completion of Wilson Dam the mussel fauna above the dam will be drowned. Ortmann found that the Tennessee River presents striking evidences of an ancient drainage entirely different from that of the present time. The lower part of the Tennessee has a rather pure Ohio type of fauna while in the region of Muscle Shoals a Cumberlandian type of fauna enters and ascending the river this latter fauna becomes more abundant as the Ohio types gradually disappear.

ECONOMIC ENTOMOLOGY

By William A. Hooker

United States Department of Agriculture

Societies.—The annual meeting of the American Association of Economic Entomologists—its 37th—was held at Washington from December 31, 1924, to January 3, 1925, with about 250 members in attendance. H. A. Gozzard of Ohio was elected President, and C. W. Collins of Massachusetts, Secretary-Treasurer. A new and revised list of common names for the more important insects occurring in North America was approved by the Association. The Association of Cotton States Entomologists held its annual meeting at Atlanta, February 3 and 4, with an attendance of 240. W. E. Hinds of Louisiana was elected President and G. M. Bentley of Tennessee, Secretary. The third annual meeting of the Rocky Mountain Conference of Entomologists was held in Pingree Park, Colo., August 17 to 22, with C. P. Gillett as Chairman and G. M. List as Secretary. The tenth annual meeting of the Pacific Coast Entomologists was held at Portland, Ore., June 18 to 20, with Leroy Childs of Oregon as Chairman and R. E. Campbell of California as Secretary. The annual field meeting of the Northeastern Entomologists was held at Washington, D. C., and vicinity on July 28 and 29 and at Frederick, Md., on July 30.

The Agricultural Appropriation Act of Congress, approved by the President on February 10, carried the sum of $2,554,743 for the Bureau of Entomology, $756,110 for the Federal Horticultural Board, and $200,795 for the enforcement of the Insecticide Act.

Insect Quarantines and Embargoes.—No new domestic quarantines against insect pests were laid, but several were extended, including those maintained against the Japanese beetle, European corn borer, and satin moth. A rehearing was held by the Secretary of Agriculture, on November 17 and 18, on the embargo against certain foreign bulbs, scheduled to become effective January 1, 1926.

Gypsy Moth.—While the gypsy moth infestation was light over most of the infested area more eggs were deposited than in the preceding season. There was, however, a very sudden increase on Cape Cod, where nearly 25,000 acres were completely defoliated. The barrier zone on the western border of the infested area was scouted and only small infestations located, all of which were treated. The territory infested in New Jersey has been so greatly reduced that only one focus was located within the outside area, fewer infestations having been found than at any time since the gypsy moth was discovered in New Jersey. An infestation discovered at Henrysburg, Quebec in 1924 was thoroughly treated and no new infestations located. No change was made during the year in the area quarantined.

Brown-Tail Moth.—This moth caused considerable defoliation in neglected apple orchards in southern Maine and New Hampshire. The infestation was light over most of the infested area, and no change was made in the quarantined area.

Satin Moth.—The satin moth spread rapidly during the year, poplars and willows being entirely defoliated in many towns extending from Cape Cod to the southern part of Maine. It now occurs in southern Maine and New Hampshire, as far west as central Massachusetts and the eastern third of Rhode Island, and locally in the State of Washington. The quarantine placed against its spread by the Federal Horticultural Board was extended on November 3 to include the States of Maine, Rhode Island, and Washington.

Japanese Beetle.—The quarantine of farm products from the infested area in New Jersey and Pennsylvania (from June 15 to October 15) has had a marked influence in restricting the local spread of this foreign invader, while the quarantine on infested nursery stock has prevented its dissemination through long distant shipments. In 1924 it extended its infestation into 5,122 square miles of new territory, but in 1925 its spread was restricted, having been the smallest in proportion of any year on record. Its economic importance. however, rapidly mounted, due to its increase in the infested area. The infestation discovered in 1924 near Milton, Pa., a point about 150 miles distant from the infested area, appears to have been eradicated, no beetles having been discovered during the year. A new attractive agent for use in control work, known as Geraniol, which was developed during the year by the Japanese Beetle

Laboratory, at Riverton, N. J., has given remarkably good results. By its use the beetles are attracted to a limited area where they can be killed by a contact spray consisting of oleoresin of pyrethrum and soap.

Mexican Bean Beetle.—This beetle continued its spread westward in Tennessee and Kentucky and now occurs over the greater part of West Virginia, southwestern Pennsylvania, southern Indiana, and practically all of Ohio.

European Corn Borer.—This important enemy of corn, first discovered in the United States in Massachusetts in 1917, has continued to spread, and from its western focus, including a wide belt surrounding Lake Erie, is now making a rapid advance into the Corn Belt. During the year approximately 18,000 square miles of new territory in Michigan, Ohio, Pennsylvania, and New York was invaded by it. A field meeting and inspection of the infested area late in October was largely attended by State and Federal officials, who were greatly impressed by the danger that threatens the Corn Belt. The growers and canners of sweet corn in western New York suffered losses of from 50 to 100 per cent. of the crop, and the indications are that the losses of this kind will be materially extended and increased in 1926.

Oriental Peach Moth.—Introduced into this country with flowering cherry stock from Japan and discovered in the District of Columbia in 1916, this serious enemy of the peach has continued to spread and now infests the territory east of the Alleghany Mountains, all the southeastern United States as far west as the Birmingham district of Alabama, and has appeared in Texas and Arkansas. In control work in New Jersey, Stearns has found spring cultivation to a depth greater than 3 in. to destroy 100 per cent. of the overwintering larvæ and pupæ on the ground about the tree. A combination fungicide-lead-arsenate-nicotine (1:800) spray gave the best control, resulting in an increase in clean fruit of 13.3 per cent.

Cotton Boll Weevil.—This enemy of cotton in its northern and eastern spread reached the limits of the Cotton Belt in 1923. The year 1925 as a whole saw a comparatively light or subnormal infestation by it, making a second in succession. The successful use of the airplane in applying the calcium arsenate dust resulted in some 80,000 acres being dusted under contract by a commercial company, with every prospect for a marked increase in 1926. An average of three applications was made, 5 lbs. being applied per acre at each application, at a cost of approximately $5.50 per acre. The closely related form of the boll weevil occurring on wild cotton in Arizona was found attacking cotton grown near by, and attempts are being made to prevent its spread.

Pink Boll Worm.—The invasion of the United States by what is probably the most serious known enemy of cotton took place in carloads of cotton seed from Mexico in 1916. The introductions in this way resulted in its infestation of cotton fields in both Texas and Louisiana. Since that time an attack has been maintained against it by the Federal and State Governments, coöperating, through the Federal Horticultural Board, and a quarantine has been maintained against all infested areas. Cotton growing in such areas has been destroyed; and all cotton from Mexico has been fumigated. As a result, all the infested areas of eastern Texas and Louisiana have been cleared of the pest, with the release during the summer of two counties in Texas. This eradication of the pest in humid areas stands as one of the most important accomplishments in applied entomology. Isolated infestations near Carlsbad, New Mexico, and in western Texas near El Paso, and in the Big Bend district still exist, no attempt having been made to stamp them out. Its invasion of Porto Rico was practically completed during the year. Its occurrence in Queensland, Australia, was definitely established.

Mosquitoes and Malaria Control.—Several cities have made use of waste crankcase oil, which can be obtained free of cost, combined with one or two parts of kerosene, in combating mosquitoes. Newport News, Va., found a mixture of equal parts to be a good larvacide. When sawdust is soaked with this mixture for four to five days it becomes saturated. Sown broadcast on the water, it sinks to the bottom, and oil is given off for four or five days, producing a continuous film. Little Rock, Ark., following the example of Memphis, Tenn., used waste crank-case oil mixed with two parts of kerosene over a control area of 68 square miles.

Insecticides and Insect Control.—It was pointed out by Moore that the common arsenical insecticides may be so manufactured that they will contain an absorbed positive ion—which insecticides then show great adherence to plants and resist the washing effects of rain and dew. Van Leeuwen, working at the Japanese Beetle Laboratory in New Jersey, has perfected a method for coating arsenate of lead. When coated with lead oleate, this insecticide is no longer a repellent to that beetle, it spreads evenly, adheres well to the foliage, and is practically unaffected by rain, which results in a saving of material and a reduction in the number of applications necessary. Experimental work in Idaho indicates that a single application of the arsenical spray is sufficient to obtain satisfactory control of the alfalfa weevil. Working with the Mexican bean beetle at the Tennessee Experiment Station, Marcovitch has found sodium fluosilicate to be less expensive and to kill more rapidly than arsenicals. A bait containing sodium fluoride was found by Ripley to have several advantages over other baits used for cutworms. Lipman and Gordon claim to have met with success in destroying, within 24 hours, all the aphids on leaves of certain trees through the injection of soluble insecticides into the trunk. Methods by which the distribution of insecticides on leaves may be made visible were described by Morgan and Newborne and by Hamilton. It was pointed out by Yothers and Winton that all emulsions stabilized with any of several colloidal substances, such as casein, milk, etc., are miscible with deep-well or hard waters and also with lime sulfur solution at dilutions varying from 1:10 to 1:100. Fish oil was found by Hood to be an efficient adhesive in arsenate of lead sprays.

Plank reported that the camphor scale seems to be well controlled by most oil sprays. Work conducted in Georgia during 1922-1924, reported upon by Alden, has shown 2 per cent. lubricating oil emulsion made from either the boiled or cold formula to give excellent control of the San José scale without tree injury even when twice used in one dormant season, while lime sulfur gave poor control. De Ong and King in California found in experiments with highly refined lubricating oils against the citrus red scale that their insecticidal value depends upon their mechanical properties rather than upon any inherent toxicity. Melander of the Washington Experiment Station found caseinate spreaders to detract from the effectiveness of oil sprays when used experimentally on San José scale and on eggs of the leaf roller. He found the lighter lubricating-oil sprays to kill as high as 98.8 per cent. of the eggs of the fruit-tree leaf roller. The onion maggot was found by Flint and Compton, in Illinois, to be largely held in check by Bordeaux oil emulsion at a cost much lower than the less effective corrosive sublimate.

Harned and Allen found that the superheating of rooms to a temperature of 120° F. or above for several hours will destroy practically all bed bugs. This temperature was easily obtained during hot summer weather by turning on the steam heat.

The discovery of the insecticidal value of the aliphatic fatty acids in the free condition, by Siegler and Popenoe, bids fair to be far-reaching in its effects. When prepared from coconut fatty acids and compared pound for pound with commercial 40 per cent. nicotine sulfate preparations, equally good results have been obtained and at a much lower cost per gallon of spray mixture. This series of products has been patented and will soon be placed upon the market under license by the inventors.

Aphid infestations of cauliflower beds were controlled by Hackett by the use of nicotine dust hydrated mixtures. In tests in Pennsylvania, Eyer found that an exceedingly high percentage of the adults and nymphs of the grape leafhopper were killed by both the "A" and "B" calcium cyanide dusts, thus confirming the results obtained by Quayle in California. Extensive experiments conducted by Fleming has led him to conclude that carbon disulfide emulsion in water is best adapted for freeing the soil about the roots of nursery stock of possible infestation by the Japanese beetle. A method by which "balled" nursery stock can be fumigated with carbon disulfide for the Japanese beetle was reported by Leach and Fleming. The use of wormseed oil and carbon disulfide emulsion as dips were found by Leach and Johnson to be the best materials for destroying the Japanese beetle larvæ present in the matted root system of herbaceous nursery stock. Used against greenhouse aphids at a strength of ¼ lb. per 1,000 cu. ft. of space, Weigle obtained 100 per cent. mortality with calcium cyanide. Woglum and La Follette found certain sprays to give results superior to fumigation for control of the black scale on citrus in California. This pest was successfully controlled by fumigation up to about 1910, since which time it has developed an increased resistance and become a serious pest over a thickly planted citrus area more than 30 miles long. A nonexplosive and noninflammable gas composed of ethyl acetate in combination with carbon tetrachloride was recommended by Back and Cotton for use in the fumigation of grain in grain cars, etc.

Insect Transmission of Plant Disease.—Working in Pennsylvania, F. T. Smith found the plant louse, *Aphis rubiphila* to be the only one of a number of insects to transmit the infection of raspberry leaf curl. The disease is transmitted from black to red raspberries, but not from red to black varieties. Olitsky found the mealybug *Pseudococcus citri* to be a vector of the mosaic virus of tobacco and tomato.

Apiculture.—One of the important developments in this field was the report by the Federal Bureau of Entomology upon a new electro-mechanical apparatus devised by Lundie, by means of which the flight of bees to and from the hive can be quite accurately determined. This opens up a wide field for investigations on the flight activities of bees. The alcohol-formalin solution, consisting of 20 per cent. formalin in alcohol, which was invented by Hutzelman for treating combs infected with American foulbrood, appears to successfully sterilize such combs.

ENTOMOLOGY

By E. Porter Felt
State Entomologist, New York

General.—There is no group which lends itself to either amateur or technical effort better than insects. They are to be found everywhere and present innumerable problems, both structural and biological. There is a marked tendency to study insects under natural conditions, stimulated in no small measure by the biology courses of schools and colleges and the sympathetic attitude of museum authorities.

The Station for the Study of Insects conducted under the joint auspices of the American Museum of Natural History and the Palisades

Interstate Park at a location near Tuxedo, N. Y., was a most interesting innovation. The plan was to show woodland and field insects under natural conditions, the various "exhibits" being located along forest paths and beside sylvan streams. There is no more inspiring educational agency than nature interpreted by a sympathetic guide.

The appeal of the wild to the expert was evidenced by the third Rocky Mountain conference of entomologists held in Pingree Park, Colo., during August and attended by a considerable number of widely scattered entomologists. "Tuning in" with nature was a conspicuous feature, though recreation and good fellowship were by no means absent.

Nomenclature.—The problem of names is a serious one for the entomologist on account of the extremely large number of genera and species he is compelled to deal with. Messrs. Felt and Bishop have proposed recently (in *Science*) a system of alphabeted prefixes to be used as a part of current generic names (the first letter of the genus to be capitalized), in an effort to secure a system of designations which would automatically place themselves in a somewhat generally recognized classification and at the same time greatly lessen the probability of the creation of homonyms—identical generic names applied to widely different forms. The system would also permit the use of shorter, more descriptive names.

Collections.—A noteworthy collection of Coleoptera or beetles containing about 16,000 species, probably 6,000 types, was bequeathed to the U. S. National Museum by the late Thomas L. Casey, together with an extensive library. This collection is one of the largest additions ever received by the National Museum. It will be arranged and made available for study by experts.

The notable E. P. Van Duzee collection of Hemiptera or true bugs has been presented to the California Academy of Science, Mr. Van Duzee retaining the privilege of temporarily withdrawing specimens for study.

The Erastus Corning collection of Lepidoptera has been transferred to the custody of the New York State Museum and this, with the collections of the late J. A. Lintner and W. W. Hill, comprise a group of private collections which greatly increase the value of the New York State collections of insects. Such disposition of private collections cannot be commended too highly. They represent years of work and study and should be placed in safe repositories rather than be allowed to slowly disintegrate, the last an altogether too common fate.

Insect Distribution.—The appearance of the *Diptera of New England*, by Charles W. Johnson is a notable contribution to faunal entomology, since it gives numerous records concerning over 3,300 species and varieties found within that area. *The New York State List of Insects*, now going through the press, includes over 16,000 species. The abundant data will do much to stimulate the interest of both amateurs and professionals in making additions to a notable work. It was to be expected that the varied climatic conditions of New York State would support considerably more than the 10,385 species recorded from New Jersey in the 1910 list. A catalogue of the Coleoptera of Michigan is being compiled.

The comprehensive work on the *Insects of Connecticut*, already marked by the issue of four large contributions, is being continued and another may be expected in the not distant future. The reporting of aphids and lady beetles from the icy North-East Land, north latitude 80°, Spitzbergen Islands, over 800 miles from the probable source of origin, is an interesting side-light on insect distribution, especially when considered in connection with the somewhat numerous records of long-distance insect spread in other sections of the world, summarized and interpreted by Felt in the issue of *Nature* for September 5.

Check Lists.—A check list of the "Diurnal Lepidoptera of Boreal America," by Drs. Barnes and Benjamin, containing many changes and additions, will be published shortly by the Southern California Academy of Sciences.

General Texts.—*The General Textbook of Entomology*, by Dr. A. D. Imms, is a comprehensive volume dealing with the anatomy, physiology, development and classification of insects, and although published in London, includes a vast amount of information with an intimate bearing upon American entomology.

Structure and Phylogeny.—Exhaustive studies along these lines by Dr. G. C. Crampton have been continued, there being an excellent descriptive account of the external anatomy of the head and abdomen of the roach (*Psyche*, 32: 195) and an exhaustive study of the phylogeny of the labium (*Ent. Soc. Wash. Proc.*, 27: 68) of holometabolous insects, with particular reference to the Diptera or the two-winged flies.

Two valuable studies of immature stages have appeared, namely, *The Morphology, Taxonomy and Ecology of Tiger Beetles*, by Hamilton, and *The Puparia and Larvæ of Sarcophagid Flies*, by Greene (*U. S. Nat. Mus. Proc.*, 65: 1-87 & 66: 1-26).

Leaf Miners.—The studies of S. W. Frost have resulted in an exceedingly useful publication (*Memoir 78*, Cornell University Ag. Ex. Sta.) on the leaf mining Diptera or flies of North America. It is understood that this and similar studies of other leaf miners may be issued in textbook form. This treatment of a group with specialized habits illustrates one of the numerous ways in which insect life can be studied to advantage to science.

Honeybee.—The literature in relation to this insect is extremely large. Yet there is room for *Anatomy and Physiology of the Honeybee*, by R. E. Snodgrass. This volume differs from many technical works in the pleasing method of presentation, the very general absence of technical terms and the thoroughness with which the matter is treated. It is a notable contribution to literature as well as a scientific contribution of inestimable value.

Gall Midges.—The appearance of *N. Y. State Museum Bulletin* 257 entitled: "Key to Gall Midges, a Résumé of Studies I-VII, Itonididæ," by E. P. Felt, completes an important study begun in 1906, the first part of which appeared in 1913. This publication summarizes our information regarding the group and includes a key to the genera of the world. The index to parts I to VII permits ready reference to the earlier portions of the work.

Stone Flies.—*A Monograph of the Plecoptera or Stone Flies of America North of Mexico*, by J. G. Needham and P. W. Claassen, issued by the Thomas Say Foundation of the Entomological Society of America, is the first comprehensive account of this important and hitherto somewhat neglected group of insects.

Bugs or Hemiptera.—*The Bibliography of North American Hemiptera-Heteroptera*, by H. M. Parshley, issued as one of the fiftieth anniversary publications of Smith College, is an author-chronological list of the more useful works dealing with this large and important group of insects. It is stated that the issuance of a *Catalogue of the Hemiptera of the World* is contemplated by Smith College authorities, *Fascicle 1, Membracidæ*, by W. D. Funkhouser, to appear shortly.

Scale Insects or Coccidæ.—Prior to the work in this group commenced by Comstock in 1880, very little was known regarding this large series of insects, some of which have come to take rank as pests of the first magnitude. An important contribution: "Classification of Scale Insects of the Sub-family Ortheziinæ," by Harold Morrison, has appeared in the *Journal of Agricultural Research* and gives a comprehensive and detailed account of the numerous species falling within the scope of this paper.

VERTEBRATE PALÆONTOLOGY

By W. D. Matthew

Department of Palæontology, American Museum of Natural History

Exploration.—The outstanding feature in the progress of vertebrate palæontology during the year and for some years past has been the extension of systematic exploration for fossils to regions hitherto little known. The extinct animals of North America and Europe have become fairly well known by a century of fossil hunting, although each year adds new discoveries. But Asia, Africa, South America and Australia are largely unexplored territory to the palæontologist; and it is in these continents that the most notable discoveries of recent years have been made.

Central Asia ten years ago was *terra incognita* to the fossil hunter. Explorations by the American Museum of Natural History and associated institutions, by the Geological Survey of China and by a number of scientific institutions in Russia, France and China are rapidly bringing together notable fossil collections and geological information. The American Museum explorations in Mongolia under Roy Chapman Andrews were continued in 1925 with great success.

Preliminary studies upon the faunas by Osborn, Berkey, Morris, Matthew, Granger, Gregory and others, published mostly in *American Museum Novitates* during 1925, indicate that Central Asia was an ancient land area with rather close connections with America in the Cretaceous and early Tertiary, with Europe and Africa in the later Tertiary; that it was the source of some but not all of the animals that appeared in the outlying continents at various epochs; and that open grassy plains followed by arid and desert conditions developed there earlier than in America and Europe. These conditions are regarded as unfavorable for the discovery of the Tertiary ancestors of man in Mongolia, but other parts of Central Asia may have been better situated.

The most remarkable discovery made in Mongolia is of the breeding grounds of Cretaceous dinosaurs. Eggs and nests of three or more different kinds of dinosaurs have been found at Shabarakh Usu; and every stage in the growth of one species, from the unhatched embryos to the adult animal, is represented by skulls and skeletons. From these same breeding grounds explorations of 1925 secured a series of skulls of the tiny mammals of the Age of Reptiles, contemporary with the dinosaurs, known hitherto by fragments of jaws and a single incomplete skull. These new skulls appear to be marsupials, but they may prove to be ancestors of the higher mammals. Other important finds are a large new horned mammal of very singular proportions, a gigantic new rhinoceros, and a great number of smaller animals. No less than forty additional dinosaur eggs were also secured.

South America.—The Field Museum has obtained a fine collection of South American fossil mammals from Patagonia and Bolivia, representing the strange extinct faunas of South America and including many rare and little-known species. Among those exhibited in the Field Museum may be seen a fine skull and jaws of a large carnivorous marsupial. In Tertiary South America, as in Australia to-day, the absence of true Carnivora gave opportunity for evolution of carnivorous marsupials of similar habits; but when the Isthmus of Panama enabled the true Carnivora of the northern world to invade South America the marsupial carnivores all became extinct. In Australia they still survive.

Africa.—The British Museum has carried on explorations in Tanganyika to secure remains of the gigantic dinosaurs first found in that region by the German explorers. Unfortunately this work has been interrupted by the death of the energetic Canadian fossil hunter, W. E. Cutler, who had charge of it. In an article on Eocene reptile bones from Nigeria, Baron F. Nopcsa sums up considerable recent evidence supporting the view that tropical Africa is and has been since the end of the Mesozoic a region of retreat and refuge for animals driven out of the northern world. Researches by Doctor Stromer of the Munich Museum on Oligocene mammals discovered in South Africa in 1921 partly support this view, but suggest also that Africa, like South America, was a region characterized by the independent evolution of a distinct fauna.

Other Fields in Australia and Tasmania in recent years have also yielded some remarkable extinct marsupials, including a skeleton of a large horned beast related to the Diprotodon, and of the giant horned tortoise, Miolania. But the Tertiary record of land animals of Australia is still to be discovered.

Researches upon large collections of fossil mammals published by the Chinese Geological Survey in cooperation with scientific institutions in Sweden have added largely to our knowledge of the extinct Carnivora and rhinoceroses of China.

A monograph on North American ground sloths by Chester Stock gives a detailed account of the occurrence and anatomy of these remarkable extinct animals. Merriam and Stock (*Pub. Carn. Inst.*, No. 347) describe the skeleton of the short-faced bear, Arctotherium, a characteristic animal of the Pleistocene of the New World.

Doctor G. Arthaber, in *Acta Zoologica*, Bd. v, 1924, gives a review of the Nothosauria, a group of early Mesozoic land reptiles from which the marine plesiosaurs appear to be descended. Many finely preserved skeletons of these interesting primitive Reptilia have been found in the Triassic and Jurassic formations of Central Europe. Another interesting extinct order of reptiles, the Placodontia, is found in the Trias of Germany, and some of the finely preserved remains in the Senckenberg Museum, Frankfurt-a-M., are described by Doctor F. Drevermann (*Abh. Senck. Naturforsch. Gesellsch.*, Bd. 38, Heft 4). These singular aquatic, mollusc-eating reptiles have never been discovered outside the Triassic of Germany. A finely preserved group of small fossil skeletons from the Permian of Saxony are described by Doctor F. von Huene as a new pelycosaurian (fin-backed reptile) (in *Geol. u. pal. Abh.*, N. F., Bd. xiv, Heft 5).

Taungs Skull.—A recent discovery of great importance is the "Taungs skull" described by Raymond Dart, from Buxton, South Africa. This skull is regarded by the best authorities as an extinct anthropoid ape which approached nearer to the human type than any of the existing apes. (See articles in *Nature* by Dart, Keith, Sollas, Broom and others, and in *Natural History* by Broom.) Its geological age is probably Pleistocene. Another important discovery is the "Galilee skull" of Neanderthal type, extending the known range of this extinct species of the genus Homo into the Near East. Another skull of the Neanderthal race was discovered this summer at Ehringsdorf in Germany. Three additional jaws of primates from the Siwalik beds of India are described by Gregory and Hellman in the American Museum Bulletin of 1925. These and other less notable discoveries are welcome additions to the very scanty evidence that the fossil record has afforded of the geological history of man and the higher apes.

ECONOMIC BOTANY

By E. L. Newcomb

Professor at the University of Minnesota

New Developments.—A number of outstanding advances in the field of Economic Botany have been made during 1925. This progress has come through activities in several rather widely different fields of botanic work.

In genetics, Mendel's Law has been an influential factor and has given impetus to the work. Studies on the hydrogen-ion concentration of the soil have influenced ecological studies and given rise to much investigation along these lines. Explorations into areas particularly in South America, the flora of which has not been completely studied, have brought to light new plants of value to mankind. Results of studies on some of these have been made public.

Medical Botany.—The favorable results obtained in medicine through the use of vitamins, insulin, and thyroxin and the detection of complex organic compounds possessing similar properties in plants have given great incentive for the restudy of practically all vegetable products used in medicine, resulting in greater attention being given to the development of medicinal plant, economic and poison plant gardens in connection with our educational institutions and pharmaceutical manufacturing establishments. The revision of the United States government standards under the Food and Drug Act has been completed during the year and many advances are recorded in the methods for testing the purity and strength of drug products as well as much new information on the morphological and chemical characteristics of plant material used in medicine.

Discoveries and Progress.—During the year, Dr. H. H. Rusby has completed the classification of the entire plant collection made on his last South American exploration. Some several hundred new species and eight new genera have been described. The complete data will be published early in 1926. The work of Dr. Rusby on these new plants has been followed closely by more economic studies by others. Dr. H. W. Youngken verified by histological studies the suggestion by Dr. Rusby that the drug "Mire" is derived from a species of *Brumfelsia* of the *Solanaceæ* and has determined the species as *B. hydrangeaformis.* Dr. T. S. Githens, working independently, has determined that "Mire" contains three principles closely related to, if not identical with, those in Manaca; namely, two alkaloids, both inducing paralysis of the voluntary muscles accompanied by twitching, and a crystalline, fluorescent principle, which is physiologically inactive. The mixed alkaloids of Caapi, another drug brought out of South America by Dr. Rusby, have been isolated in crystalline form in the laboratory of Seil, Putt & Rusby and are now being studied in the Mulford biological laboratory with respect to physiological action.

Agricultural Remedies.—Much progress has been made toward the development of agricultural plants which are disease resistant. Dr. E. C. Stakman, M. N. Levine and F. Griffee reported in *Phytopath.* 15: 691-698, 1925, the discovery of a variety of wheat which is resistant to black stem rust. Dr. J. G. Dickson has reported a strain of corn resistant to seedling blight and that wheat similarly immune is being developed. Dr. G. W. Keit announced that apple scab is about to be conquered. Working in greenhouses in which all sorts of weather and conditions can be produced at will, Dr. Dickson found that the fungus causing seedling rot was thwarted in its attacks upon the tender plant when the plant builds up a woody armor. This happens in the case of corn when the soil is warm, whereas in cold weather only mucilage-like substances are grown which provide a luxurious and destructive living for the fungus. The new corn has been bred so that it will grow as resistant to the fungus in cold weather as in warm. A strain of smut resistant corn has also been developed by workers in the Department of Plant Pathology at the University of Minnesota.

Vegetable Drugs.—New editions of the United States Pharmacopoeia and National Formulary were completed in 1925 and contain revised standards for some two hundred vegetable drugs and their preparations which will become official under the Federal and various State Food and Drugs Acts during 1926. These standards reflect the completion of a large amount of research carried out by Dr. Henry Kraemer, Professor E. N. Gathercoal, Dr. E. L. Newcomb, Dr. Carl Alsberg, Dr. Arno Viehoever, Dr. Albert Schneider, Dr. C. A. Dye, Dr. W. O. Richtmann, G. M. Beringer and O. A. Farwell. New or rewritten descriptions of all of the more important vegetable drugs have been prepared by these workers. The descriptions include the whole drug, the structure and the powder. Much new morphological data are included in these descriptions, especially with reference to the size of microscopic elements.

Determinations.—In preparation for the new standards, some twelve thousand determinations on the inorganic constituents of vegetable drugs were made. These results together with some fifty thousand determinations by other workers including alkaloidal assays, physiological assays and other assays were compiled by E. L. Newcomb, who served as the chairman of the sub-committee on Botany and Pharmacognosy during the latter part of the revision, and formed the basis for new standards. Over ten thousand specimens representing the material worked with, are now carefully indexed and preserved at the University of Minnesota and available for reference. A special committee, under the chairmanship of E. L. Newcomb, made extensive investigation on the subject of uniformity in size of particles of powdered drugs, and standards are now provided. Numerous new tests and assays of vegetable drugs have been included, all of which assure to physicians and the general public greater uniformity and potency in medicinal agents derived from plants.

Plant Oils.—Anton Hogstad, Jr., published during the year the results of a series of extensive experiments carried out in the Medicinal and Poisonous Plant Gardens at Brookings, South Dakota, on the origin and manufacture of oil of Chenepodium. The results proved conclusively that a physiologically active oil could be produced in the locality. E. B. Fischer of the Department of Pharmacognosy of the University of Minnesota reported during the year on the yield of volatile oil from various economic plants grown in the Medicinal Plant Garden at the University of Minnesota. The results supply important data for the development of the volatile oil industry in the Northwest. F. A. Upsher Smith has continued the cultivation of *Digitalis purpurea* and the production of the drug Digitalis in Minnesota and reported assays showing very high potency.

Miscellaneous Contributions.—Many other contributions in the field of Economic Botany have been made during 1925. The following are deserving of special mention: Pollen Morphology by Maxy Alice Pope, *Botanical Gazette,* 80: 63-72, 1925. "Some effects of seasonal conditions upon the chemical composition of American Grape Juices," J. S. Caldwell, *Journal of Agriculture,* Research No. 12, June, 1925. "Oxygen supplying power of the soil as indicated by color changes in alkaline pyrogallol solutions," Lee L. Hutchins and B. E. Livingstone, *Journal of Agriculture,* Research XXV. Dixon —"On ascent of sugar in plants"— Blakiston, London. The Constitution of Cellulose, A. W. Schorger, *Industrial and Engineering Chemical Journal,* 16: 12, p. 1274. The Chemistry of the Rubber Hydrocarbon, H. L. Fisher, *Industrial and Engineering Chemical Journal,* 16: 6, p. 627. Insulin-like action of vegetable extracts. Sil. Med. Klinik, 21-169.

DIVISION XXXIII
MEDICAL SCIENCES

PHYSIOLOGY

By Percy G. Stiles
Harvard Medical School

When the attempt is made to summarize the progress of a branch of science in any fixed period of time there is an important consideration which should be stressed. It is to this effect: that while we are compelled to choose for enumeration the studies which have an appearance of completeness, the future advances will probably be in the line of those which now seem to be tentative and fragmentary. The selection of particular investigations for mention here does not indicate that they will prove to have the most permanent value but that they are adapted for description by reason of their clean-cut and concrete character.

The Neuromuscular System.—Conspicuous for its interest among the publications of 1925 is the paper by Henderson and Haggard on the performance of a champion Yale crew. Reliable measurements of the force exerted by these eight athletes when driving their shell at twelve miles per hour show that they developed each about one-half a conventional horsepower. To sustain such activity the heart sent to the muscles a tide of blood capable of contributing to their use upwards of three liters of oxygen per minute. At the maximum the release of energy in the system reached about twenty times the rate at rest. Even the huge oxygen supply did not keep pace with the strict requirement; the muscles "went into debt for oxygen," collecting payment in the term of deep breathing that followed the exertion.

What is the fuel burned by the muscles? This is a question which has not been easy to answer. Some additional evidence has been gathered which tends, on the whole, to support the traditional teaching that carbohydrate is the favorite but not the invariable source of power. Fat may undoubtedly be used when necessary but whether it can be utilized in its original form or must be changed to carbohydrate has proved difficult to determine. A. V. Hill of Cambridge, England, believes that the preliminary transformation is essential. Furusawa has shown by trials with human subjects that a diet made as rich in fat as practicable is quite unfavorable to efficient muscular activity. Indications multiply that the level of the blood sugar has a definite relation to muscular efficiency.

The Liver.—In view of this reference to the blood sugar it is appropriate, at this point, to cite the work of Bollman, Mann, and Magath. These investigators have made it clear that the disastrous effect produced upon an animal by the removal of the liver is primarily due to the reduction of sugar concentration. The glycogen deposits of the liver are normally drawn upon to hold the sugar of the blood up to a proper standard. A late report emphasizes the distinction between the availability of the liver glycogen for this purpose and the inutility of the other glycogen store, that which is held in the muscles. The hepatic cells release their carbohydrate whenever the blood sugar is slightly subnormal;

the muscle fibers are far more tenacious of their stock.

Rhythm in the Nervous System.—For many years there has been a voluminous discussion as to the typical frequency of the impulses passing along nerve-trunks. By artificial stimulation we know that we can force the rhythm to very high values but it would be of particular interest to find out how rapidly the succession is maintained in the processes of natural living. This was the starting point of the ingenious experiments of Gasser and Newcomer in 1921. They attempted an analysis of the discharge sent by the respiratory center to the diaphragm of a dog at each inspiration. Another obvious possibility is the study of the flow from the spinal cord to a muscle which is reflexly contracted. This has been done by Forbes and Olmsted.

To understand their method one must be familiar with the following facts. The disturbance which travels along a nerve-fiber as the result of a solitary stimulus has a magnitude which does not depend on the strength of the shock producing it. After an impulse has passed, the fiber quickly, but not instantaneously, regains the power to conduct again. If it is forced to respond to a fresh stimulus before its recovery is complete it will transmit a disturbance which is conceived to be of a subnormal intensity. According to this principle the stimulation of the nerve-fibers by electric shocks in excess of a certain frequency will give rise to a series of impulses which are individually diminished in potency. Such subnormal impulses may be arrested in a partially anesthetized section of the nerve through which full-sized impulses would succeed in making their way.

At the mammalian body-temperature a nerve can conduct about 330 impulses per second and they can retain the standard magnitude of isolated impulses. A higher rhythm of stimulation cuts them down. Now Forbes and Olmsted have found that partial anesthesia of a motor nerve during the execution of a reflex act may block the transmission from the cord while not interfering with artificial excitation of a limited frequency. It is inferred that the impulses issuing from the centers have commonly a rhythm in excess of 330 per second. This estimate is considerably above those which have generally been favored.

The Volume of the Circulation.—There has been a long controversy among physiologists as to the average output of the heart and the extent to which it may vary from time to time. The quantity of blood expelled by either ventricle at a beat is known as the "stroke volume." The "minute volume" must evidently be the product of the stroke volume by the pulse rate. It has been difficult to devise a reliable method for measuring the heart's delivery and very different opinions have been held in regard to it. About three years ago Henderson appraised the data available and came to the conclusion that the normal stroke volume of the human heart is large and relatively constant. Since then his own work with Haggard has led to a decidedly different conclusion.

A new technique has been contrived for determining the quantity of blood passing through the lungs and therefore through the heart. A gas, ethyl iodide, harmless in the low concentrations employed, is inhaled by the subject. Certain physical facts concerning the power of the blood to absorb this gas at various tensions have been established. Analyses of the air breathed in and out afford a basis for calculating how much blood must have flowed through the pulmonary vessels to remove definite amounts of the gas. The method is comparatively simple and does not involve the assumptions which it has previously been necessary to make. The results point to a highly variable stroke volume.

Apparently the heart of a man who weighs 70 kilograms usually discharges rather more than 100 c.cm. of blood from each ventricle at a beat. The output per beat increases surprisingly when exercise is taken. It may be doubled. This is the conclusion which is most at variance with earlier views. It had been taught that when the pulse rate of a man beginning to use his muscles went up from an initial 75 to a maximum of 150, the stroke volume changed but little and the minute output was therefore just about doubled. If, however, the stroke volume doubles as well as the rate the minute delivery must be quadrupled. The resting value is set by Henderson and Haggard at about 7.5 liters and the maximum during exercise at 30. In some individuals the stroke volume is much larger when lying down than when standing.

The Spleen.—This rather large organ has long baffled the attempts of many workers to fix upon it a function commensurate with its size. It has come to appear probable that the chief relationship of the spleen is with the red corpuscles of the blood. In the past the action most discussed had been the possible disintegration of these cells within the spleen. Work now going on in the laboratory of Barcroft in England indicates a totally different type of action. The organ is exhibited as a reservoir of corpuscles which may be expressed from it into the circulation when the need is definite.

A preliminary report is to the effect that the spleen of the cat undergoes intense contraction after hemorrhage. The change has been made visible by the X-ray. It is so great as to transfer to the blood as much as 20 c.cm. of fluid. Barcroft believes this fluid to be quite as rich in red cells as the blood itself. The volume mentioned is large enough to be of vital consequence in many cases. Thus, the gradual loss of 60 c.cm. of blood from the body of a cat may be compensated in part by the addition of 20 c.cm. of blood, or its equivalent, from the spleen. With magnitudes of this order the splenic reserve may well save life.

Confirmation of Barcroft's conception has been obtained by observing the resistance of animals, with and without the spleen, to the fatal influence of carbon monoxide gas. This gas causes death when it has so far replaced oxygen in the arterial blood as to deprive the tissues of their essential supply. The end will, clearly, be postponed if fresh portions of hemoglobin can be introduced into the circulation. This is precisely what the spleen is now held to do. Animals deprived of the spleen and given a reasonable time to recover from the operation have succumbed to carbon monoxide decidedly sooner than normals. This is really due to the loss of the splenic resources and not to operative injury. Control experiments in which other abdominal operations have been performed serve to show that the surgical procedure does not in itself make the system more susceptible to the gas. Cutting the nerves of the spleen prevents it from functioning in such an emergency.

The Pancreatic Juice.—In the field of digestion we may note a change of emphasis in regard to the factors affecting the flow of a important secretion. Until rather recently the chief responsibility for the timely awakening of the pancreas to periodic activity was fixed upon the acid entering the duodenum from the stomach. It has been taught that the acid reacting with material in the duodenal mucosa produces a more or less specific "secretin" adapted to pass as a hormone to the pancreas and to excite its cells. It now appears that other influences than that of acid deserve to be considered and indeed to be given primacy.

We have in mind the observations of McClure and his co-workers. It is their constant experience that food rather than acid in the small intestine induces the flow of pancreatic juice. Neutral fat which requires this agent for its digestion is reported to be highly efficacious in calling it forth. Furthermore it is stated that acidity seems not to be maintained to a significant degree in the duodenum. The chyme from the stomach is promptly neutralized. Nervous control of the pancreas probably plays a larger part than was recognized a short time ago.

The Endocrine Organs.—Since the preparation of insulin was achieved a great deal of work has been devoted to the making of concentrated and stable solutions and precipitates of the various hormones. Attention may be called to the work of Collip on the parathyroid. For some time it has been known that the removal of the parathyroid tissue commonly produces tetany which may be fatal. Lately it has been noted that a characteristic of this condition is a lowering of calcium in the blood. The acute symptoms are relieved by injecting calcium salts into the circulation. The inference has been that the parathyroid exerts a regulatory influence upon the calcium content of the plasma.

Collip has obtained an active parathyroid preparation by an acid hydrolysis of the glands. The material thus secured can be used to preserve the lives of animals from which the parathyroids have been removed. This it appears to do by elevating the blood calcium from a subnormal to a normal figure. The extract can be given with benefit by the mouth but is more effective when injected under the skin. Collip has found that excessive doses of the new hormone may force the calcium definitely above the concentration which is desirable. A complex of symptoms may be developed which is clearly the result of this disturbance of the chemical balance.

Another aspect of endocrine activity is presented in a paper by Britton. The reference is to the nervous control of the discharge of insulin from the islet cells of the pancreas. It will be remembered that there is abundant evidence that the internal secretion which makes possible the normal metabolism of carbohydrate is a product of these cells. There is further testimony from histologists to the effect that the "Islands" have a liberal nerve-supply. It has, accordingly, been a matter of interest to ascertain whether the nerves in question have a demonstrable influence upon the rate of insulin discharge.

In the present state of our knowledge it is necessary to draw conclusions concerning insulin in the blood from determinations of sugar. The sugar level is very sensitive also to changes in the rate of adrenal secretion. Britton controlled this complicating factor by eliminating the adrenal medulla from nervous connections. He found that the blood sugar in animals thus prepared was remarkably constant over long periods. If, at any time, the right vagus nerve was stimulated at an accessible point upon the stomach the sugar fell decisively. The character of the change was always such as may be observed after a suitable injection of insulin. In view of many details which cannot be recounted here it may be stated that the body of evidence secured by Britton is exceedingly impressive. Nervous control of insulin release appears to be surely established.

Size and Metabolic Rate.—There is a large literature dealing with the correlation between size of body and intensity of metabolism. During the current year there have been fresh contributions to the discussion, and attention may be called to one by Wels. Tissues from different animals have been removed to appropriate media and their consumption of oxygen has been measured. The tabulated results indicate that the specimens taken from small mammals have a distinctly greater oxygen requirement than those from larger organisms. The following figures will illustrate the principle.

OXYGEN IN CUBIC MILLIMETERS PER HOUR AND PER MILLIGRAM OF DRY WEIGHT OF TISSUE

	Young Mouse	Adult Mouse	Young Rat	Adult Rat	Guinea-pig	Rabbit	Sheep
Muscle	13.4	10.6	7.5	5.7	3.5	..	..
Liver	..	10.8	..	..	4.4	4.5	3.1

It is fair to add that this suggestive gradation has not been confirmed by Terroine and Roche who have made a somewhat similar investigation.

Sympathetic Innervation of Skeletal Muscles.—From time to time the claim is renewed that the striped muscles of the body are more or less influenced through sympathetic (autonomic) connections. Many have favored the conception that while the rapid and forcible contractions are doubtless caused by the obvious and direct nerve-supply from the cord or medulla, gradual and gentle adaptive changes may be governed through the ganglia of the sympathetic chains. The histologists have described nerve-endings in skeletal muscle which may represent the terminals of such paths. The matter has been much discussed because of the operations of Hunter. This brilliant Australian surgeon, lately deceased, had reported the relief of certain conditions of contraction in paralyzed legs, following the removal of the lumbar ganglia.

Meek and Crawford have published the results of experiments on dogs which do not confirm the existence of autonomic regulation for the leg muscles. They have dissected out the lumbar ganglia and allowed the animals to recover. After a considerable interval (33 to 77 days) they have destroyed the cerebral hemispheres. When this operation is performed with careful attention to the precise limits of the injury it is well known that the animal may show what is called decerebrate rigidity. This is, in general, an exaggerated tonus of the extensors. It is, furthermore, a plastic tonus, meaning by this a condition which admits of manipulating the limbs into various positions and having them retain these postures.

If the easily recognizable plastic tonus is due to an autonomic influence it should not appear after the excision of the sympathetic ganglia. When the operation has been on one side only there should be a contrast between the reactions of the two legs after decerebration. Meek and Crawford have been unable to discover any such contrast. So far as their results are concerned there is no evidence that the destruction of sympathetic connections modifies in any respect the behavior of striped muscle. The possibility remains that different species of animals differ in this feature of their organization. Hunter and Royle derived their positive data largely from the goat and the fowl and from human patients to whom they brought benefit. Still other studies of this question may be expected.

PHARMACOLOGY

By Robert A. Hatcher

Professor at Cornell University Medical School

Significance.—Pharmacology is concerned with the actions of drugs on living tissue and is the basis of scientific therapeutics. The discovery of the effect of a rare chemical on one of the lowest forms of life may be the starting point for epoch-making advances, and a sensational discovery may be quickly forgotten because of changing conditions; hence some of the facts that are mentioned here may ultimately prove of less importance than others that are not discussed.

There is urgent need of investigation in every field of medicine, and the public should understand that scientific research is not an amusement of "highbrows" but the work of the most practical of men who appreciate its vital importance, since it touches the health of every individual. Medical progress may be likened to the slow spread of light at dawn, while the brilliant discovery may be compared to the sudden flood of light that follows an eclipse of the sun.

Insulin.—The discovery of insulin was one of the triumphs of medicine, but its initial cost and other disadvantages limited its use. Dr. John J. Abel, who has studied organ extracts for many years, and his co-workers, have purified insulin, obtaining a product several times as active as that previously used. Its chemical behavior suggests that insulin is an unstable compound of sulphur, and it seems probable that it can be standardized chemically, thereby saving at least one thousand rabbits for every lot prepared. Philip Shaffer and his associates have also greatly improved the manufacture of insulin.

Pituitary.—Pituitary (also known by various names) is valuable in child-birth, but owing to the lack of accurate means of determining the activity of its preparations fatal accidents have resulted from overdosage, and disappointment has resulted from insufficient dosage. M. I. Smith and W. T. McClosky of the Hygienic Laboratory of the United States Public Health Service recently developed a satisfactory method of standardizing these preparations, and this method will be adopted throughout the civilized world. Abel has prepared a substance from the pituitary of such extraordinary activity that it causes active contraction of certain muscles even when it is diluted with 18,750,000,000 parts of water.

Iodin and Goiter.—Simple, or nontoxic, goiter is prevalent in many parts of the world. This relatively harmless condition is often followed by the far more serious exophthalmic, or toxic, goiter, which is also known as Grave's disease. Simple goiter is relieved or prevented by small amounts of iodin or an iodid, but it is difficult to induce very large numbers of persons to take the treatment, and in Switzerland, where the disease is extremely common, the law requires that a trace of iodid be added to table salt, thus insuring its prophylactic use. Thousands of school children in various cities in the United States have been treated with an iodid, and it has been suggested that it be added to the water supply. This is too expensive, however, for general adoption since only a small percentage of the water supplied to a city is taken into the body. Iodin has been used in the Mayo Clinic and elsewhere in the treatment of the toxic form of goiter, and quite recently C. C. Sturgis and J. A. Greene in the Peter Bent Brigham Hospital of Boston reported that its use before thyroid operations had resulted in greatly lessening the loss of weight at that time.

Tetany.—The parathyroid glands were so named because of their proximity to the thyroid. Their removal in healthy animals results in a spasmodic condition known as tetany, suggesting that an active extract of the glands might prove useful in disease presenting similar symptoms. J. B. Collip, who assisted in the preparation of insulin, has prepared such an extract, which influences the amount of calcium in the blood. It gives promise of being useful in the treatment of tetany in infants and in that following injury to the parathyroids during operation for removal of the thyroid.

Salvarsan.—The unquestioned value of arsphenamine (salvarsan, "606") is marred by the fact that it sometimes causes death. Reid Hunt, of Harvard Medical School, has determined experimentally the causes of certain of these accidents and has shown how they may be avoided. Workers in the Rockefeller Institute have continued the study of various compounds of arsenic which are used in the treatment of lues and the African sleeping sickness (not the so-called sleeping sickness of Europe and the United States). It seems probable that tryparsamide (one of these arsenicals) is of especial value in the treatment of neuro-syphilis, but certain disadvantages remain to be overcome. Workers in the Hygienic Laboratory believe that those arsenicals that have high penetrative power should be given the preference over those of lower power.

Antimony and arsenic have certain actions in common and efforts are being made to determine in what conditions antimony may replace the latter. Pharmacologic tests of two selected preparations of antimony (one of which had been synthesized by Professor Abel) showed that they were less toxic than tartar emetic when injected subcutaneously in mice, and Dr. Alexander Randall used them in the treatment of granuloma inguinale. He closes a recent report with the statement that antimony is rapidly receiving attention, because of its value in the treatment of so-called tropical diseases.

Use of Diuretics.—Dropsy, or edema (an accumulation of water in the tissues) results when the kidneys fail to function properly, and the effective use of diuretics constitutes one of the problems of the treatment of cardiac disease. Novasurol (a complex substance in which mercury and a hypnotic are combined) was introduced for the treatment of lues, but it has recently attracted attention as a diuretic, especially in dropsy due to cardiac disease. It has the advantage over calomel, which has long been used as a diuretic, of being soluble in water, hence it may be injected intramuscularly or intravenously. Urea is a normal constituent of the urine, and more than thirty years ago, it was used as a diuretic, but it was supposed that the symptom known as uremia was due to the inability of the kidney to excrete urea, and it dropped out of use as a diuretic. During the present year, J. H. Crawford and J. F. McIntosh used it in the Hospital of the Rockefeller Institute for Medical Research and reported that it is useful in cases of heart disease with edema in which treatment of the heart itself failed to afford relief.

Quinin and Quinidin.—The use of quinin and quinidin illustrates what has been stated somewhat differently in the first paragraph of this article, in that the present methods of using them are not dependent upon any great discovery of recent years, but upon the correlation of the results of studies in widely separated fields. Quinin is now used far more effectively in the treatment of malaria, and while quinidin does not cure heart disease, we know more of its limitations than we did, and relatively fewer accidents result from its use.

Soma Weiss, in Bellevue Hospital, found that suitable doses of physostigmin (also called eserin) relieve the distressing gaseous distention of the bowels so often encountered after abdominal operation. This drug had been used on theoretical grounds for this purpose, but the doses employed were insufficient and frequent disappointment had resulted in its falling into disuse.

It was observed that one part of ethylene in a million of air caused certain flowers to close, and Arno Luckhardt studied the actions of the gas on animals and man. These investigations showed that it is a general anesthetic of relatively low toxicity and it is coming into extensive use. It has the disadvantage of forming an explosive mixture with air.

Hookworm.—The prevalence of hookworm disease in various parts of the world has led to the treatment of whole populations en masse, and many thousands of cures have been effected by the use of oil of chenopodium (American wormseed), and the far less expensive carbon tetrachlorid.

Recent experience makes it doubtful whether chaulmoogra oil, or its esters, actually cure leprosy or only cause marked improvement. The oil is obtained from the seed of a tree which grows in the jungles of Burma and adjacent regions and the Government of the United States is making great efforts to increase the supply.

Extraordinary efforts are made to discover antiseptics that will destroy organisms of disease in the human body. The oral administration of hexyl-resorcinol to man causes the urine to become bactericidal; hence it is hoped that the drug will prove useful in chronic infections of the bladder. Churchman and others are investigating certain dyes intended for use as internal antiseptics and there is reason to believe that distinct advances will be made in the near future.

Cancer and Radium.—The value of radium in the treatment of cancer has been amply demonstrated and studies are being made to determine the best methods of employing it. Fortunately, the extremely limited world supply is being rapidly augmented.

Dr. Emil Mayer, chairman of a special committee of the Council on Pharmacy and Chemistry of the American Medical Association, collected detailed reports of forty-three deaths following the use of cocain and other local anesthetics. The committee studied these reports and concluded that local anesthesia can be induced safely according to the methods formulated.

Poisoning with corrosive sublimate, by accident or design, occurs frequently. It causes intense suffering and death or prolonged invalidism. The search for an antidote continues actively, but there is no satisfactory method of treating the distressing symptoms after the poison enters the circulation. Sodium thiosulphate (commonly called hyposulphite) is being used extensively as an antidote in poisoning with this and other metals, but with far from uniform success.

Anemia and Iron.—The public pays a considerable sum every year for so-called tonics, and it has long been thought that medicinal iron is of value in certain forms of simple anemia. C. S. Spenser and H. N. Ets rendered rats anemic by hemorrhage and found that they recovered as rapidly without medicinal iron as with it, since the common foods contain an abundance of iron for ordinary demands. Anemia is not usually due to any deficiency of iron in the food, but to an inability of the patient to utilize it. Green vegetables and red meats contain all the iron that is required.

Digitalis.—Digitalis is pre-eminent among the drugs used in heart disease, but its therapeutic use presents many problems concerning which there is a very great diversity of opinion.

Professor Cushny has studied the enormous literature of the subject and his book of more than three hundred pages, just published, treats of the action and uses of digitalis and other drugs of the group. Cushny has performed a great service to medicine and to mankind in clarifying many questions concerning these drugs. A perusal of this book enables one to appreciate the force of the statement that medical progress is due mainly to the slow accumulation of knowledge based on experimental evidence.

Pharmacopœia.—The tenth decennial revision of the United States Pharmacopœia has been completed after more than five years of work, and it became official (legal standard) on January 1, 1926. It represents a prodigious amount of exacting labor, and much credit is due Professor E. Fullerton Cook, the chairman of the Committee of Revision, for the success of the work. It represents the best in the materia medica and there are very few, if any, non-proprietary drugs, which are essential in the treatment of the sick, that are not described. Many useless or superfluous drugs that were formerly included have been dropped, and probably it is the best national pharmacopœia ever issued.

Abraham Flexner, who has studied intensively the problems of medical education in Europe and the United States, says (Medical Education, The Macmillan Company, 1925), "Perhaps the most efficient and stimulating teaching of pharmacology is found in the small number of high-grade schools in America." The significance of this statement is appreciated by those who understand that continued therapeutic progress is dependent upon pharmacologic development.

PATHOLOGY

By A. James Miller, M.D.
University of Nebraska Medical School

Hemochromatosis. — The tissue changes and the method of their production in hemochromatosis are described by Mallory.

Hemoglobin is broken down in such a way that hemofuscin, a yellow pigment, is formed and stored in the liver. It is found in the parenchymal cells and in the endothelium lining the sinusoids first. In the course of months or years the hemofuscin is changed to hemosiderin. After the liver cells are filled to a certain degree they die and regeneration follows. Later the connective tissue, plain muscle of the blood-vessels and bile duct epithelium take up the hemofuscin and here it is also but very slowly changed to hemosiderin. Necrosis, regeneration and sclerosis follow the deposit of pigment.

When the liver is saturated the

pancreas, cortex of adrenals, lymphnodes, heart, thyroid, skin and mucosa of the stomach take up the pigment. The pancreas may go through tissue changes similar to those in the liver and diabetes mellitus result. Destruction of the adrenal cortex may lead to an increase of normal pigment, or melanin.

A group of 19 cases are reported. Of these 9 had used alcohol to excess, 6 had been exposed to copper for years by their occupations, 1 had used a copper kettle regularly for boiling water. In three instances the histories are negative for exposure to copper. The required time of exposure is years; the most definite history is that of a man who turned copper and brass for 14 years.

Analysis of a group of distilled liquors showed the presence of copper from a trace to 185 mg. per liter. The solvent action of organic acids on the copper worm of the condenser or other copper containers is believed to be the source of the copper. Fine copper shaken up with 1 per cent. solutions of nitric, hydrochloric, acetic, tartaric, lactic and citric acids for 15 minutes was dissolved to a perceptible degree.

The disease was reproduced in laboratory animals by giving them copper. The change of hemoglobin to hemofuscin and then to hemosiderin was followed. These changes may be produced in the body in other ways so copper is only one of the things that brings it about. The very high instance of exposure to copper in the histories of the reported cases points quite definitely to copper poisoning as the etiology, especially when confirmed by the reproduction of the disease in laboratory animals.

Scurvy. — The structural changes characteristic of the scorbutic state are described by Wolbach. Guineapigs deprived of the anti-scorbutic factor are the subject of the investigation.

The earliest effect of the scorbutic state is found in the incisor teeth and is evidenced by defective dentine formation and changes in size, arrangement and staining reaction of the odontoblasts. In 6 or 7 days there is separation of the dentine forming cells from the dentine leaving a space which is presumably filled with fluid. Within 48 hours after giving the antiscorbutic factor there is formation of dentine filling this space.

Bone formation ceases immediately on withdrawal of the anti-scorbutic factor but osteoblasts continue to proliferate. A single dose of this factor results in the prompt appearance of bone matrix between the cells. There is no repair of bone incisions in the scorbutic state. If, however, the anti-scorbutic factor is given immediately after a bone incision in a scorbutic animal new bone formation is very prompt.

Fibroblasts proliferate in the scorbutic state but there is very little intercellular substance formed. New blood vessel formation is also retarded in granulation tissue.

The scorbutic state is characterized by the inability of the supportive tissues to produce intercellular substances. This is most marked in the tissues which have calcified products, as bone and dentine, applies less to collagenous tissue and cartilage and by inference to other intercellular substances. The hypothesis that intercellular substances are changed from a liquid to a jell state that the anti-scorbutic factor brings about this jelling, or setting, is entertained.

Fat Soluble A Deficiency.—A description of the tissue changes in animals fed a fat-soluble A (vitamin) deficiency diet with mention of the report of one fatal case, has also been made by Wolbach.

The changes effect epithelial tissues and consist of the "Substitution of stratified keratinizing epithelium for normal epithelium in various parts of the respiratory tract, alimentary tract, eyes, paraocular glands and genito-urinary tract." The replacement epithelium is common in type for all locations. The change occurs by proliferation of small groups of cells arising from the original epithelium and not by a general transformation. Changes are absent in the stomach, intestines, liver and kidney parenchyma.

Growth activity of cells is augmented. The mitochondrial apparatus is not primarily changed.

NON-TUBERCULOUS GRANULOMATOUS LYMPHADENITIS

Hansmann calls attention to a disease recently recognized in this country but commonly recognized in France.

Clinically it is manifested by a small cutaneous lesion which is wartlike, vesicular, ulcerated or indurated. These are probably different stages of the same process. It occurs on any part of the integument and is common on the genitalia. Enlargement of the regional lymph-glands soon follows during which time there may be general symptoms including fever, leukocytosis, nausea and vomiting. After about two weeks the fever subsides and the process advances slowly. The glands may adhere to the skin, break down and discharge through sinuses. The pus is sticky at first but loses this character after secondary infection. The glands are walled off by granulation tissue and are not tender or hot until secondarily infected.

The pathology of the primary lesion consists of ulceration, hyperplasia of the epithelium, induration and leukocytic infiltration accompanied by a few giant cells. It heals after a few weeks.

The pathology of the lymph-nodes so closely resembles that of tuberculosis that it is very difficult to differentiate. The chief difference is that there is more suppuration and tubercle bacilli are not found.

The etiology is not known. Animal inoculations are without positive results.

Good recovery follows surgical excision.

Pellagra.—A study of twelve uncomplicated cases of pellagra has been made by Denton, who found the important lesions in the skin, in the mucosa of the mouth and in the large intestine.

In the skin there is rarefaction of the superficial part of the corium and destruction of the collagenous binding material between the dermis and epidermis. Shallow vesicles result with no evidence of positive pressure. Telangectases develop in the corium by distention and growth of preëxisting capillary and precapillary vessels.

The lesions in the mouth are similar but may become necrotic and secondarily infected. Their color is due to the telangectases.

Colitis is very common and may give rise to no noteworthy symptoms unless the sigmoid and rectum are involved. Here the epithelium is intact save for microscopic areas of necrosis covered by fibrinous exudate. Numerous cysts are formed by dilated glands in which the epithelium reverts to a more simplified type. Varying grades of acute inflammatory reaction are always present. The epithelial cells change to a wide variety of sizes and shapes with mitoses and irregular cell division. The vessels are dilated similar to those in the skin. The changes are confined to the epithelial tissues without extension to the deeper tissues or viscera.

There is no direct insight into the etiology. The similarity of the lesions to those produced by the X-ray is mentioned.

BACTERIOLOGY

By William H. Park, M.D.
Department of Health, New York

New Discoveries.—During the past year a number of minor additions have been made to our knowledge in Bacteriology, but those that were important require further work for their corroboration and those that were less important hardly deserve mention among outstanding features. In this article, therefore, the subjects have been limited to three, Tuberculosis, Cancer and Scarlet Fever.

In Tuberculosis the discovery of the value of the vaccine treatment is not new but the report on its use in children is new. The discovery of Dr. Gye's in tumors is absolutely new. This work has not been corroborated as yet but it is done so carefully that it deserves to be considered, although it will take years to determine the exact value of the discoveries.

In Scarlet fever, like Tuberculosis, the discoveries are not altogether new. Like Tuberculosis, the present success is based upon years of study and it is also fair to mention that a well-trained bacteriologist in Italy, —Carinia.—believes he has discovered a different organism than the streptococcus which produces immunity. Dr. Carinia, and Dr. Turnicliffe also believe they have discovered a tiny streptococcus which they believe to be the cause of measles. It will take another year at least to determine the value of their findings.

Tuberculosis.—For many years Professor Calmette has been attempting to obtain a safe and reliable vaccine against human tuberculosis.

Ever since Koch in 1890 published his work on tuberculin this problem has been a subject of investigation. Behring prepared a vaccine for calves which was quite successful, but had important drawbacks. Calmette uses for his vaccine a strain of tubercle bacilli obtained from cattle and which after long years of cultivation upon media containing bile has become so attenuated that it is not able to infect rabbits, calves or monkeys. He found that after vaccination the animals were resistant to infection with tuberculosis for a year or more and that each revaccination would give another year.

On June 16 he published the first results obtained from the vaccination of human infants. These infants were born of tuberculous parents, they therefore were in great danger of infection and early death. They were vaccinated during the first days of life.

These vaccinations were begun in 1922 and have been continued in ever increasing numbers until the present time. Up to June 1, 1925, Professor Calmette has been able to trace 423 of these infants who were vaccinated at least six months previously, and none of them have died of a tubercular infection.

In view of the usually heavy death rate from tuberculosis in infants, born of tuberculous parents, these results are strikingly favorable.

Cancer and Malignant Tumors.—Dr. Gye gave an address at the British Medical Association in July on his work on the etiology of malignant tumors. Dr. Payton Rous of the Rockefeller Institute for Infectious Diseases reported in 1911 that if a certain variety of chicken sarcoma was removed, ground up in a mortar with sand, diluted with an adequate amount of salt solution and filtered first through paper pulp to take out the coarse particles and then through a Chamberland filter that this filtrate though free of any cells which were visible under the microscope was able to produce a sarcoma if injected into other chickens. Subsequently two other varieties of sarcoma were discovered, the filtrate of which had the same power as that from the Rous sarcoma, originating tumors imitating in their nature the tumors from which the filtrate was made.

Dr. Gye's results indicated that the filtrate contained a living virus and a specific substance derived from the tumor tissue. The living virus after passing through successive cultures was still potent so that it seemed that growth had certainly taken place. Each of these alone was incapable of giving rise to a malignant growth but combined they were able to produce it. These results were obtained not only with tumors from birds but also from mammals. The discovery that the virus alone was not able to start the development of a tumor without the aid of this specific substance obtained from the tumor tissue and that this specific cellular material determines the nature of the tumor is an original idea of great interest.

This discovery of Gye's is a step forward which will stimulate many other workers to try to corroborate it and to extend it. There is no prospect that this discovery will be of immediate help in the treatment of malignant tumors, but experiments are already being carried on in London on the possibility of vaccinating man so as to produce an immunity to the disease.

Scarlet Fever.—More than twenty years ago Moser developed a serum which had marked therapeutic results with scarlet fever, and Gabrischewsky developed a vaccine made of the broth in which the streptococcus obtained from scarlet fever cases had grown and of the dead streptococci themselves. This was used in tens of thousands of Russian children and apparently gave protection against scarlet fever. Outside of Austria and Russia the serum and vaccine was not appreciated.

The recent discovery of the Dicks that the streptococcus from scarlet fever throats made a toxin that when injected into the skin, just as the diphtheria toxin is done in the Schick test, of a non-immune person would develop a slight inflammatory reaction and that the same toxin injected into the skin of an immune child would not develop a reaction, made it possible to do a number of important things. The presence of natural or acquired immunity could be determined, the antitoxic potency of serum could be estimated and the development of immunity as well as its duration in children could be determined.

At the same time as the Dicks, Dochez developed a highly antitoxic scarlet fever serum. The potency of the serum was determined by the Schultz-Charlton blanching test. If 1 c.c. of the serum from a convalescent case of scarlet fever is injected into the skin of an early case of scarlet fever the redness disappears from the skin in the area injected.

During the year 1925 papers have been published showing the striking results in early cases of a sufficient amount of antiscarlatinal serum and the effectiveness of the vaccine has also been demonstrated. The immunization is generally complete in two weeks and lasts in the majority of persons for at least a year.

The serum and vaccine bid fair to be as useful as diphtheria antitoxin and toxin-antitoxin. The latter is being very widely used in the United States and the results have been very successful. As already stated, a number of additions have been made to our knowledge of bacteriology and immunology during the year but they are mostly either not of general interest or lack confirmation.

MEDICINE

By F. Lowell Dunn

Professor, University of Nebraska Medical School

Fields of Progress.—The year 1925 appears more in the light of an extension of principles previously enunciated rather than one of new discoveries. This makes a selection of material difficult, and somewhat individualistic. Perhaps edema, insulin, pernicious anemia, light therapy, the stethophone, liver function, and scarlet fever are the more important fields of progress. These have been selected. Recent work on cancer and the visualization of the gall-bladder by the use of tetraiodeophenolphthalein and similar compounds will be considered in the section on surgery.

Eminent Men.—The deaths of Sir James Mackenzie and Sir Clifford Albutt cannot be passed over lightly. Mackenzie, through his careful observations of heart abnormalities while a practitioner, did fundamental work in heart irregularities and prognosis of heart conditions. His painstaking records on patients over periods of several decades and longer, combined with his critical judgment, enabled him largely to reshape the knowledge of cardiac disorders and to place it on a rigid basis. Mindful of the value of such study over periods of years he pointed out repeatedly that the family doctor was pre-eminently fitted to study the course of disease and that all important progress need not come from the laboratory or the clinic.

Sir Clifford Albutt died at the age of 88 years. Aside from the large system of medicine which he edited, his works on arterial disease, hypertension and angina pectoris are considered classical contributions. It is of interest that he introduced the short clinical thermometer into medicine. Its usage today is so routine that we seldom think of the significance of such a step. The above is sufficient to indicate that two pioneers have passed. Professor August von Wassermann died at the age of 59. The Wassermann reaction, a complement fixation test in syphilis, is widely known among the laity and of great value in diagnosis because of the manifold variations in syphilis.

In literature the fascinating biography of Sir William Osler by Harvey Cushing will appeal to all who are interested in biography or in American medicine. The profusion of letters and anecdotes gathered reflects the thoughtful and painstaking care of its author and makes the two volumes a permanent contribution.

Edema.—The work of W. B. McClure and C. A. Aldrich on the time required for the disappearance of intradermally injected salt solution (J. A. M. A. 81: 1923: 293), together with later study of a case of generalized edema by this method seem to show conclusively that edema is a tissue-thirst phenomenon. In cases with edema the injected salt solution disappears rapidly whereas the normal disappearance time on the leg for 0.2 c.c. is about forty-five minutes. Brown and Rowntree (Arch. Int. Med., 35: 1925: 129) in a study of the volume and composition of the blood and the changes incident to diuresis in cases with edema come to the same conclusion. This is essentially the older viewpoint of M. H. Fischer (Edema and Nephritis) and is in close alignment with the development of colloidal chemistry with its work on the swelling of proteins, effect of electrolytes, and influence of semipermeable membranes. The preliminary report of G. M. Curtis shows that the action of certain diuretics (euphyllin) is on the tissues and not on the kidneys alone (Berliner Klin. Wochenschrift, 1925).

Novasural.—A double salt of sodium mercurichlorphenyl oxycetate with diethylbarbituric acid (barbital), is a new diuretic favorably commented on by Rowntree, Keith, and associates in the treatment of ascites in hepatic disease and also in nephritis with edema (J. A. M. A., 1925). Studies of the blood failed to show any constant changes in the concentration of hemoglobin, serum, protein or chlorine coincident with the loss of fluid. The loss of fluid is usually prompt and striking. There are no data on the permanency of such treatment.

These authors suggest that their work is further evidence that changes of a physicochemical character; probably affecting the cellular colloids, are responsible for the edema. Linking up edema with a field of colloids in this manner does not in any sense simplify our understanding of the problem; but by shifting the attention to the tissues will lead us away from the mechanical explanations of edema, which have not proved of great use.

Insulin.—It is premature to form final opinions as to whether the use of insulin will or will not completely neutralize the disease, diabetes mellitus. Joslin, Root, and White (J. A. M. A., 85: 1925: 420) state that diabetic children under insulin management may be underweight for their age but have normal weight for their height. Development seems to go towards a normal maturity. This is in great contrast to the hopeless outlook of pre-insulin days. Fitz and Murphy (Arch. Int. Med., 1925) conclude that in adults taking insulin and under control as to glycosuria, the muscular efficiency is approximately normal, provided sufficient calories are given.

However, the intermittent injection of insulin would not *a priori* appear to be as effective as the flexible insulin control of the non-diabetic. At present the operative hazard in diabetics in properly trained hands is scarcely greater than in the non-diabetic. Because of the potential instability of a diabetic Jones and Root point out that all infections requiring surgery should be treated early. As to the possibility of curing diabetes by the continued use of insulin over long periods of time there is no reliable evidence. By resting the islet tissue of the pancreas by the injection of insulin very definite increases in the ability to burn carbohydrates are shown, but the final tolerance established is below that of the nondiabetic individual.

The mechanism of action of insulin is not known. Of interest, however, is the report of Abel, Geiling, Alles, and Raymond (*Science*, Aug. 21, 1925) that the potency of an insulin preparation runs parallel to its sulphur content. They also observed that alkalinizing an insulin preparation destroyed its activity, and that on acidifying again the preparation gave off hydrogen sulphide. This would indicate that the activity of insulin depends in part on a labile sulphur linkage. This work looks very promising. There is much work reported on the formation of intermediate glucose compounds due to the action of insulin. These are supposed to be more active forms. These compounds are in such small proportions, however, that the analytic methods have large sources of error.

Pernicious Anemia.—Kahn and Torrey (*Proc. Soc. Exp. Biol. and Med.*, 22: 1925: 8) have repeated the work of C. A. Herter reported in 1906 on the presence of Bacillus Welchii in the stools of cases of pernicious anemia; and the effect of injecting the toxins from cultures into animals. They noted constant presence of these bacilli in unusually large numbers in 33 cases, and produced anemia in monkeys resembling markedly that of pernicious anemia. They also noted some of the usual clinical signs in the monkeys such as desquamation of the tongue and nervous disorders of mild degree. The clinical picture of pernicious anemia is striking in its uniformity and baffling in its etiology. Many organisms have been suggested previously. However, the viewpoint that the disease is due to a hemolytic toxin is widespread and the lack of free hydrochloric acid in the stomach contents has led many to believe that the source of the toxin is in the intestinal tract.

Light Therapy.—The significance of radiations in the visible and ultra-violet regions in metabolism and disease is rapidly being realized. The antirachitic effect of sunlight is well known. Hess and his associates have recently shown that certain substances (phytosterol and cholesterol) became antirachitic after being exposed to ultra-violet radiations. Then also Leonard Hill, Colebrook and Eidinow (*Brit. J. Exp. Path.* 5: 1924: 54) have shown that radiation of blood increases its bactericidal activity when returned to the blood stream. There is much evidence that by absorption of radiation active molecules may be formed which carry on beneficial processes in the organism. Many reactions in chemistry at the present time are believed to be due to the absorption of radiation and not due primarily to the inherent energy of the reacting substances. Such reactions have been shown to be accelerated markedly by using monochromatic radiation of certain wavelengths. The use of monochromatic radiation in the study of biologic processes has just begun. Such work will teach us much about the energy relations of these processes and also concerning the selective destruction of malignant tissues.

Stethophone.—This is a vacuum tube amplifier devised for classroom demonstration and for study of the sounds heard by the stethoscope. Briefly it consists of an electromagnetic transmitter in contrast to the usual carbon grain type, a three stage amplifier, a selected group of electric filters and a multiplicity of output receivers for observers. (H. A. Frederick and H. F. Lodge, *Bell System Technical Journal*, 3: 1924: 531.) The power amplification of the instrument is estimated at about one hundred million times. It is built into a substantial cabinet on wheels resembling a tea-wagon, permitting easy transportation. The electric filters are combinations of inductance and capacity which function to cut out various frequencies. They are variously described as low-pass, *i.e.*, passing only low frequencies, high-pass, and band-pass. By the use of trunk lines and jacks an entire classroom may be fitted up so that the instructor and all students may hear the heart sounds at the same instant. R. C. Cabot and H. F. Dodge (*J. A. M. A.*, 84: 1925: 1793) have done preliminary work on the frequencies of the sounds heard in the chest. It is observed that most of the sounds of clinical interest are below 1,000 cycles per second. Of interest is the complexity of the sounds heard in physical diagnosis. By varying the combinations of filters the composition of these sounds may be analyzed. Such work is being done. By connecting to a suitable galvanometer the vibrations may be photographed, or if desired phonograph records may be made so that permanent auditory records may be kept. In the delivery room by using a loudspeaker the fetal heart tones may be heard throughout birth. This should be of value in difficult deliveries, for by its use the condition of the child may be followed more easily than at present. The future of this instrument is problematic but it is not unreasonable to expect that it will assume a rôle similar to that of the electrocardiograph in heart disease.

Liver Function.—Although various tests for liver function have been described for several decades and longer, their clinical use has been very rare until recently. Within the last few years, however, extensive work has been done in order to determine their value. The work at the Mayo Clinic, Rochester, Minn., is of particular value with comparative tests in experimental animals and in the clinic. The Van den Bergh test for the presence of bile pigments in the bloodstream and the excretion of the dye phenoltetrachlorphthalein by the liver are proving of definite value. The former enables a quantitative estimation of bile pigment and also permits detection of excess bile pigment in the blood when it is not clinically obvious. The dye test, which is based on the rate of disappearance of the dye from the bloodstream after being injected intravenously, will often detect damage in the absence of clinical signs of its damage. According to these authors retention as shown by the dye almost always means liver damage, but the absence of retention does not rule out liver damage. The liver is the largest organ in the body and there is much evidence that it subserves numerous functions. The above tests are based on only a few of these functions. Tests based on the relation of the liver to carbohydrate and protein metabolism do not appear to be clinically useful, although they give fairly consistent data in the experimental animal. It is problematic whether any single test will be developed that will give an index of liver function. Possibly we shall be compelled to test out various functions of the liver in order to gain a comprehensive knowledge of its injury.

F. C. Mann has recently summarized his extensive work on the surgical removal of the liver in various species of animals. While the exact evaluation of results depending on the removal of entire organs is difficult, Mann has shown a definite regulatory mechanism for carbohydrate by the liver. The blood sugar falls progressively with the characteristic symptoms seen with excess doses of insulin. These are counteracted by giving glucose. In his work urea formation did not occur after the liver was removed, indicating that the protein breakdown products, the amino acids, lost the amino group through the action of the liver. Bile pigments were formed even though the liver was absent. These are important and much debated questions and the decisive character of Mann's experiments is needed.

Scarlet Fever.—The work of G. F. Dick and G. H. Dick has cleared up the question of etiology of this disease (*J. A. M. A.*, 81: 1923: 1166). The disease has been produced experimentally in man and it has been shown that a streptococcus is the agent. The possibility of a filterable virus seems excluded. The demonstration that a true toxin is produced similar to that in diphtheria has resulted in the preparation of a concentrated scarlet fever antitoxin (*J. A. M. A.*, Mar. 14, 1925). Non-concentrated antitoxins have been used previously but serum reactions are troublesome. The Dicks in Chicago have made comparative tests in

56 cases using 35 as controls and giving 21 antitoxin. The basis of selection was to give the more severe cases antitoxin. No deaths occurred, but it is significant that in the control series, 8.5 per cent. showed postscarlatinal nephritis, 14.2 per cent. otitis media, 8.5 per cent. mastoiditis, and 2 per cent. showed severe cervical adenitis, while in the more severe cases the only complication was otitis media in one (4.7 per cent.). These were cases that were given antitoxin on the first day of the rash. In a second group of cases which were classed as severe there were 20 per cent. deaths in the 15 controls and 3.4 per cent. in the 29 antitoxin cases, *i.e.*, one death which was due to a neglected mastoid infection. The best results are obtained when the antitoxin is given in one dose in the early stages of the disease. If enough has been given the rash will show definite fading within 24 hours, the course of the disease will be shortened, and with the reduction in toxemia the complication will be more easily recognized. Park reports similar results (*J. A. M. A.*, 85: 1925: 1180). A dosage of 2,000 to 10,000 units, he states, will usually be sufficient. It would seem that another disease is under control.

SURGERY

By Herbert H. Davis

Professor at University of Nebraska Medical School

Preoperative Treatment. — Considerable progress is constantly being made in reducing surgical mortality and morbidity. Preoperative preparation of the patient saves many lives and many articles are being written on this subject. Hemorrhage following operation on jaundiced patients is reduced by giving calcium preoperatively. The exophthalmic goiter case is greatly improved by giving iodine before operation. Cases of septicemia are often greatly benefited by giving of mercurochrome intravenously. An intestinal obstruction toxemia is improved by giving chlorids and hydrochloric acid. Insulin makes the diabetic a better risk. Kidney function tests and blood chemistry enable us to find out more about the general condition. Therefore fewer and fewer unexpected complications are arising.

Cancer.—The cancer problem is being very diligently worked on. Drs. Gye and Barnard of Edinburgh, Scotland, have cultivated a filterable virus which they claim to be the cause of cancer. There has been a great deal of premature and unfortunate newspaper publicity on this work. Dr. George A. Soper, the Managing Director of the American Society for the Control of Cancer, went to Europe to investigate the research. He states that not all experimental workers there were convinced that the whole of this work would be corroborated. Nobody thought that the entire causation of cancer had been explained. Dr. Gye, himself, while expressing confidence in his results, did not claim to have unraveled the whole problem and wished it understood that his results, even if fully confirmed, by no means indicated how cancer could be cured.

Carcinoma of the Esophagus.—Being a relatively slow growth in this location, carcinoma of the esophagus up to the present time has been practically 100 per cent. fatal. It very often gives no signs early and therefore becomes rather advanced before the patient seeks medical aid. The greatest difficulty in treatment, however, is the inaccessibility. X-ray and radium have been very unsatisfactory in this location and really only a palliative measure. In January was published a symposium on surgery of the esophagus. Dr. Franz Torek presented a case of cure of carcinoma of the esophagus by surgery. This woman, who is now 78 years old and enjoying very good health with no signs of recurrence, was operated by Dr. Torek in June, 1913.

Dr. Carl Eggers reports a case operated by Dr. Torek's technic, who is well and healthy about two months following operation. Of course, it is too early to tell whether this will be a permanent cure or not. Both of these cases had the diagnosis definitely proved microscopically.

After a primary gastrostomy the patient's physical condition was improved by feeding through the tube into the stomach. At a second operation a large incision was made almost the entire extent of the left seventh intercostal space and continued upward in the back, cutting through the seventh, sixth, fifth, and fourth ribs. As the pleura was then opened the length of the above mentioned incision, positive pressure anæsthesia was used. The esophagus was tied in two places below the tumor and cut off between the ligatures. The lower stump was inverted. Then practically the entire length of the thoracic esophagus was loosened. An incision over the left sternocleidomastoid muscle of the neck was made extending down to the upper end of this freed esophagus. It was then pulled through this opening so as to lie on the anterior chest wall. The tumor mass at the lower portion of the esophagus was then cut off and a tunnel made through the subcutaneous tissue for the remaining portion. The large incision and the incision in the neck were then closed. This left the patient with an opening on the chest wall at the lower end of the esophagus. By a rubber tube connecting this with the gastrostomy tube the patient was able to eat in a normal manner.

Lilienthal in 1921 did an extrapleural resection and plastic operation for carcinoma of the thoracic esophagus. His case was dismissed from the hospital in good condition but died several months later of recurrence.

At Lenox Hill Hospital in New York twenty-six such operations had been done with two recoveries. However, with more experience and earlier diagnosis this should be improved upon. This mortality is very high but without this operation the mortality is practically 100 per cent. It should be left to the patient whether he wishes to take the chance.

Dr. Duff S. Allen reports considerable experimental work on reconstruction of the esophagus. Two stout silk ligatures are placed around the esophagus at the ends of the section which is to be removed and a cuff of fascia lata is placed around this. The ends of the untied ligature are brought through this fascia. After healing has taken place the ligatures are tied very tightly and entirely buried, by suturing other tissue over them. This causes the portion of the esophagus to slough away leaving the fascia intact. The danger of this is stenosis following the operation.

Cholecystography. — Graham and Cole in 1924 brought forward a method for Röntgenographic visualization of the gallbladder following intravenous injection of the sodium salt of phenoltetrabromphthalein. This substance is secreted through the bile by the liver.

This year Whitaker and Milliken have improved the technic by using sodium tetraiodophenolphthalein. This is about twice as opaque to X-rays as tetrabromphenolphthalein. Elements are opaque to X-ray approximately in proportion to their atomic weights. The atomic weight of bromine is 80 while that of iodine is 127. The toxicity of the two drugs is practically the same. Therefore a smaller dose of the tetraiodophenolphthalein is used. This gives a greater margin of safety.

It has recently been found that sodium tetraiodophenolphthalein given by mouth may be absorbed from the intestine and give the gallbladder picture. It is easier to give this way, the danger of injecting a little into the tissues, which causes a slough, is avoided, and reactions are lessened.

If a clear-cut picture of the gallbladder of normal shape is shown it indicates a normal gallbladder; if the picture shows no shadow there is probably a pathological gallbladder. Failure to show a shadow may be due to obstruction to the cystic duct, loss of the concentrating function of the gallbladder, or to very advanced liver disease so that the drug is not secreted into the bile.

Several thousands of patients have been examined by this method and no deaths reported. Dr. Graham reports 550 cases. Given by mouth it is necessary to coat the material with something that will pass through the stomach unaltered. If the acid of the stomach is allowed to act on the substance, the soluble sodium salt is converted into the insoluble free acid which will, therefore, not be absorbed. For this purpose various capsules and tablets have been devised.

Dr. Graham states that the intravenous method has given accurate results in 93 per cent. of the cases and the oral method in 70 per cent. However, if either method shows a gallbladder shadow, the gallbladder is probably normal. If the oral method fails to show a shadow it is advisable to check up the result by the intravenous method. If still no shadow is seen (allowing for 7 per cent. error) the gallbladder is diseased.

Tannic Acid in the Treatment of Burns.—There is considerable evidence that the constitutional reaction in burns is due to a toxemia. The causative substance is probably the product of protein autolysis in the burned tissue.

Tannic acid has the property of precipitating protein. Dr. Davidson, on the assumption that by precipitating protein it could not be absorbed, began using tannic acid in the treatment of burns. He reports 25 cases with much better results than have been accomplished by other methods. Two of the cases were fatal. One of them he thinks would probably have lived had he not applied boric acid solution on the sixth day of treatment. The case had been doing nicely with the tannic acid treatment and became worse soon after the boric acid solution was used. Other cases have shown that boric acid solution is detrimental. The second fatal case lived twenty-two days, but finally died of exhaustion and secondary infection of the deeply burned tissues, at a time when the non-protein nitrogen of the blood was normal and other evidence of the so-called burn toxemia was absent.

As soon as a patient is seen he is given a relatively large dose of morphine sulphate hypodermically to alleviate the intense pain. The burned area is then covered with dry sterile gauze pads which are held in place by sterile gauze bandages. This dressing is then soaked with 2.5 per cent. or 5 per cent. aqueous solution of tannic acid. It is essential that the tannic acid solution be made up fresh just before use because it deteriorates upon standing with the formation of the far less astringent gallic acid. Small sections of the dressing have been opened for inspection at the end of 12, 18 and 24 hours. As soon as the surface has assumed a light brown color all dressings are removed. Pain and trauma are avoided by wetting the gauze with fresh tannic acid solution shortly before it is removed. The wound is thereafter left exposed to the air but is carefully protected from mechanical injury, chilling, and bacterial invasions by a suitable cradle draped with sterile linen. In the more serious cases artificial heat is supplied by placing ordinary electric light bulbs in the cradle. About the face a 5 per cent. tannic acid ointment is used. This is not so satisfactory as the solution. It is important to keep up the fluid balance of the body by forcing fluids. Blood transfusions are occasionally necessary.

His conclusions are as follows: (1.) The preliminary treatment of burns with tannic acid compresses followed by exposure to air lessens toxemia. (2.) After coagulation of the devitalized tissue with tannic acid, the application of a wet boric acid dressing apparently causes a return of toxic symptoms. (3.) Tannic acid as an initial dressing on a burn is analgesic. (4.) The subsequent use of the open air method causes minimal trauma and promotes general comfort. (5.) The local astringent effect prevents the loss of body fluid. (6.) Secondary infection is markedly limited by the absence of a favorable nidus for bacterial growth. (7.) Scar tissue formation has been less marked than that observed after treatment by other methods. (8.) The protective layer of coagulated protein forms a scaffold for the growth of the young epithelial cells over the denuded surface.

Lymphaticostomy for Peritonitis.—Dr. W. A. Costain of the University of Toronto in 1922 first published results of experimental work on the treatment of peritonitis by drainage of the thoracic duct. He concluded that in diffuse septic peritonitis death travels through the thoracic duct and drainage of this duct would be valuable aid in the treatment. About that time he treated the thoracic duct in a child for pneumococcus peritonitis with recovery.

The results of several important investigations have been published this year in regard to this treatment. Lehman and Copher experimentally found this did not help peritonitis but thought it might be slightly favorable for toxemia of intestinal obstruction. L. D. McGuire has done a very careful series of experiments. He found that two out of four dogs in which he ligated the appendix and meso-appendix lived, and stated therefore that Costain's lethal standard was incorrect.

In carefully controlled animal experiments McGuire drained the thoracic duct after producing peritonitis. In culturing the lymph from the thoracic duct in six dogs he was able to get a positive culture in only one, the other five being sterile. Injecting the lymph into the blood of rabbits found it had no harmful effect. Therefore, toxic material was not coming away through the thoracic duct.

Moreover, in his experiments drainage of the thoracic duct seemed to have no effect on peritonitis. The work of Cox and Bell lead to much the same conclusions as that of McGuire.

There is evidence of three modes of absorption from the peritoneal cavity, namely: by blood stream, by lymphatics through the anterior mediastinum to the right lymphatic duct, and by the lymphatic duct. Therefore, in draining the thoracic duct we are only removing a small amount of the septic material.

The work done this year seems to indicate that, at least in most cases, draining the thoracic duct does not benefit peritonitis. It is a rather serious operation to attempt on a person as ill as these patients usually are. However, the question is not yet entirely settled.

PUBLIC HEALTH AND HYGIENE

By C. E. A. Winslow

Professor at Yale University School of Medicine

Studies on Cancer.—The basis of all public health work is a knowledge of the etiology of disease; and in this fundamental field the most notable development of the year 1925 was the work of Gye and his associates on cancer (*Lancet*, July 18, 1925, CCIX, pp. 109, 117 and 135). This remarkable series of investigations appears to indicate that malignant growths contain a cultivable virus (or viruses) apparently demonstrable by special methods of photography, which has the power of producing tumors when inoculated into animals simultaneously with tumor extract containing a "specific factor." Neither alone is capable of producing this result. The virus is non-specific, either for tissue or species; while the specific factor, as its name indicates, is definitely specific both for species and tissue. The significance of this relationship remains to be determined; and since there is a dual chain of causation no conflict is involved with the well-grounded epidemiological conclusion that cancer is not in actual experience a communicable disease. The results seem to harmonize much that has been obscure, and to contradict nothing that is well established, in regard to the etiology of cancer. They may very probably open the way to further advances of the first magnitude.

In connection with the general subject of cancer, mention may also properly be made of the admirable statistical study of Schereschewsky (*Public Health Bull.* 155, U. S. P. H. S.) demonstrating the real increase in cancer mortality in the registration States since 1920.

Control of Diphtheria and Scarlet Fever.—Diseases due to defective environmental sanitation, careless disposal of excrement, polluted water or milk supplies and the like, are rapidly disappearing from civilized communities. Thus, the typhoid rate for the larger cities of the United States averaged 3 per 100,000 for 1924 as against 20 in 1910; and only two cities (Nashville and Memphis) had in 1924 rates as high as the average for 1924. (*Jour. A. M. A.*, Mar. 14, 1925, CXXXIV, p. 813.)

Communicable Diseases.—On the other hand, the communicable diseases which are spread primarily by direct contact between one human being and another are much more difficult to control. With diseases of this class the production of artificial immunity by the use of sera and vaccines is our most effective weapon. Smallpox, for instance, has practically disappeared from countries with efficient autocratic governmental machinery and persists as a disease of democracy where the right of the individual to contract disease whenever he so desires is actively maintained. Thus the statistics of the Health Section of the League of Nations show that in 1924 there were only 16 cases of smallpox in Germany, 126 in Poland and 190 in Italy—against 1,234 in Switzerland, 3,765 in England and Wales and 55,537 in the United States.

The campaign for the control of diphtheria by Schick testing (to determine whether a child is already immune against this disease) and active immunization of those not already protected, by the use of toxin-antitoxin, has continued to make rapid progress during 1925. In dealing with younger children (which is the really important objective since over 50 per cent. of deaths from diphtheria occur under five years) it is now believed to be wisest to omit Schick testing and immunize all children directly. The Metropolitan Life Insurance Company and the State Charities Aid Association are backing a "No Diphtheria by 1930" campaign along these general lines in New York State.

In the case of scarlet fever we have now, thanks to Dochez and the Dicks, a similar test for immunity and a serum for treatment which is as effective as diphtheria antitoxin. All the work of 1925 (see *Jour. A. M. A.* for March 14 and for May 16, 1925) tends to confirm our faith in the value of these procedures and to show that scarlet fever, like diphtheria and smallpox, is now entirely within our control.

Studies in Tuberculosis.—During the year 1924, two potentially important discoveries were announced in connection with tuberculosis, the Calmette vaccine and the Möllgard sanocrysin chemotherapy. No conclusive report on either of these subjects has yet been made public but reports of progress by various investigators during 1925 are on the whole distinctly favorable to the former, and distinctly unfavorable to the latter, mode of treatment. Calmette's experiments on cattle and monkeys and clinical experience with some thousands of vaccinated infants all seem to indicate that the strain of tubercle bacilli which he has prepared is harmless, in the sense that it cannot produce disease in men or in animals, while it has retained the power when injected, or when taken through the mouth by young babies or young calves, of producing a real immunity, lasting several years. Whether this vaccine will be widely used for human beings or not, it seems worthy of extensive use in the protection of dairy cattle. On the other hand, Schroeder, Park and Smith in their studies of the gold compound, sanocrysin, suggested for the treatment of tuberculosis find that the effect of this drug on tuberculous animals is unfavorable rather than otherwise and they doubt whether it exerts any such specific effect upon the tubercle bacillus as was first postulated by the Danish observers. (W. H. Park, Biggs Memorial Address, N. Y. Acad. Med., Nov. 19, 1925.)

Oysters and Typhoid Fever.—Among the epidemiological events of the year, the outbreak of typhoid fever caused by oysters during the winter of 1924-5 is of outstanding importance. Some 900 cases in New

York, over 100 in Chicago, some 60 cases in Washington and many scattering cases in other cities, bringing the total to 1,500, were conclusively traced to oysters distributed by a Long Island producer. (*Jour. A. M. A.*, Feb. 28, 1925, LXXXIV, p. 641; and Supplement No. 50 to *Public Health Reports*, U. S. P. H. S.) The exact methods by which the oysters were polluted remains, however, a mystery since the layings from which they were ostensibly derived were of excellent character. The epidemic led to valuable studies on the viability of bacteria in oysters during storage and to a constructive symposium at the St. Louis meeting of the A. P. H. A., in the course of which the importance of purifying oysters by storage in chlorinated sea water was specially emphasized.

Pasteurization of Milk.—Bacteriologists and health administrators alike have been engaged during the year in a vigorous and sometimes acrimonious controversy in regard to milk pasteurization. A special study on Commercial Pasteurization (*Public Health Bull.*, No. 147, U. S. P. H. S.) including exhaustive bacteriological tests under field conditions led to the conclusion that 142° was a sufficiently high minimum temperature to ensure the destruction of pathogenic organisms. This view has been hotly contested by other experts and the question at issue as well as the whole problem of milk supply from an economic standpoint is now to be thrashed out by a special committee on Dairy Products of the American Public Health Association, of which Professor H. C. Sherman is chairman.

Dietary Hygiene.—In the field of dietary hygiene the most significant recent advance has perhaps been the extension of work on the dietary factor related to fertility. Evans and Mason (*Proc. Nat. Acad. Sci.*, July, 1925, XI, pp. 373 and 377) have shown that in the male as well as in the female the absence of the fat soluble "E" vitamine (found in lettuce leaves, milk fat, beef musculature, wheat germ, etc.) from an otherwise adequate diet leads to complete sterility accompanied by extensive degeneration of the reproductive tissues. The work of the last five years tends more and more to emphasize the fact that a diet adequate for growth may lack subtle elements which are essential for longevity, resistance to disease and reproductive power, and to remind us that the importance of an adequate diet is far greater than we have hitherto realized.

Industrial Poisons.—Notable progress in the development of public policy toward health hazards in industry has been made as a result of a series of fatal cases of lead poisoning arising in the manufacture of tetraethyl lead, the new "anti-knock" constituent of motor fuels. A conference called by the Surgeon General of the Public Health Service in May (*Public Health Bull.* No. 158, U. S. P. H. S.) led the Ethyl Gasoline Corporation to discontinue the manufacture of its product pending investigation and report by a special committee appointed by the Surgeon General—a precedent of the first importance. A somewhat similar, though unofficial, study of the hazards of benzol poisoning, conducted by a sub-committee of the National Safety Council has led to the conclusion that this substance is so dangerous that xylol, toluol or other less harmful solvents should be substituted for benzol in industrial processes wherever possible (Proc. Cleveland Meeting, N. S. C.).

Mental Hygiene.—In the field of mental hygiene, the publication of A. L. Gesell's book on *The Mental Growth of the Pre-School Child* (Macmillan, N. Y., 1925) is an event of major significance, pushing back our quantitative measurement of mental development into the early years of infancy and showing that the ultimate "mental age" of an adult can be predicted with reasonable closeness before the second year of his childhood. The whole problem of feeble-mindedness is nowadays being approached from a broader and saner viewpoint with the recognition that mental defect is not the deadly hereditary curse that amateur reformers sometimes paint. It is often not hereditary at all; and we are discovering that in the less acute forms of such defect we can "learn to live with the feeble-minded" and to make them reasonably useful citizens.

The Gorgas Memorial.—The Gorgas Memorial Institute of Tropical and Preventive Medicine has begun active operations during the year, with special emphasis on the control of tropical diseases and on the promotion of periodic health examinations, both specially appropriate tributes to the conqueror of yellow fever and the director of the Army draft examinations. The Republic of Panama has made generous provision toward the research institute to be created on the Isthmus; and in this country an active educational campaign has been conducted through the newspapers and by the use of radio, while mosquito control has been initiated in Cook County, Illinois.

Health Demonstrations. — Encouraging reports of progress come from the Commonwealth Fund Child Health Demonstrations at Mansfield, Ohio; Fargo, North Dakota; Athens, Georgia; Rutherford County, Tennessee; and Marion County, Oregon. The Milbank Tuberculosis and Health Demonstrations in Cattaraugus County, N. Y., and Syracuse, N. Y., are developing rapidly and are already yielding substantial results; while a third demonstration in the Bellevue-Yorkville section of New York City has been inaugurated. The East Harlem Health Center in New York City has issued an interesting summary of its first three years' work.

Standardization of Community Health Activities.—One of the most important events of the year has undoubtedly been the remarkable progress of the campaign initiated for the standardization of municipal health work by the Committee on Administrative Practice of the American Public Health Association. The first important step along this line was the survey of 83 large cities conducted by the Committee in 1921 (*Public Health Bulletin* No. 136, U. S. P. H. S.). In 1923 the United States Public Health Service surveyed 100 cities of over 70,000 population (results not yet published); and the American Child Health Association surveyed 86 cities of 40.000 to 70,000 population. The latter survey appeared in October, 1925, and is an admirably conducted survey, clearly and forcefully presented, giving a vivid picture of the status of the public health movement as a whole and of the achievement of each individual city, which should be studied in detail by every student of the problems of preventive medicine.

Meanwhile the Committee on Administrative Practice, with the aid of the American Child Health Association and other voluntary agencies and of a group of coöperating health officers, was preparing an Appraisal Form for the measurement of the actual status of community health work on an objective and quantitative basis. This form was issued in a tentative preliminary edition in 1924 and proved so valuable to the health officer in enabling him to gauge the effectiveness of his program and to secure official support for it, that a revised and approved Appraisal Form will be issued for general use in January, 1926.

VITAL STATISTICS

By William H. Davis

Bureau of the Census, Department of Commerce

Federal mortality statistics are compiled only for the death registration area and Federal birth statistics only for the birth registration area (Mortality Statistics and Birth, Stillbirth, and Infant Mortality Statistics —annual reports—published by the Bureau of the Census.)

A "registration area" is that portion of the United States recognized by the Federal Government as having adequate registration laws and registration at least 90 per cent. complete. December 31, 1925, the death registration area includes 41 states, the District of Columbia, the Territory of

Hawaii, and 14 cities in nonregistration states, or 91.6 per cent. of the total population of the United States, and the birth registration area includes 33 states and the District of Columbia, or 75.9 per cent. of the population of continental United States.

Vital Statistics Goal.—As this book goes to press the Bureau of the Census is endeavoring to reach the goal—*Every State in the Registration Area before 1930.*

The following tables show the state growth of the two areas:

STATES IN DEATH REGISTRATION AREA

State	Year	State	Year	State	Year
Massachusetts	[1]1880	Maryland	1906	North Carolina[6]	1916
New Jersey		Pennsylvania		South Carolina	
District of Columbia[2]		South Dakota[4]		Tennessee	1917
Connecticut	[1]1890	Washington	1908	Illinois	1918
Delaware[3]		Wisconsin		Louisiana	
New Hampshire		Ohio	1909	Oregon	
New York		Minnesota	1910	Delaware	1919
Rhode Island		Montana		Florida	
Vermont		North Carolina[5]		Mississippi	
Maine	[1]1900	Utah		Nebraska	1920
Michigan		Kentucky	1911	Georgia	1922
Indiana	1900	Missouri		Idaho	
California	1906	Virginia	1913	Wyoming	
Colorado		Kansas	1914	Iowa	1923
				North Dakota	1924

[1] Census year ending May 31.
[2] Included in registration States.
[3] Dropped from the registration area in the census year 1900.
[4] Dropped from the registration area in 1910.
[5] Included only municipalities having a population of 1,000 or more in 1900.
[6] The remainder of the State of North Carolina was added to the registration area in 1916. (See note 5.)

STATES IN BIRTH REGISTRATION AREA

State	Year	State	Year
Connecticut	1915	Ohio	1917
Maine		Utah	
Massachusetts		Virginia	
Michigan		Washington	
Minnesota		Wisconsin	
New Hampshire		California	1919
New York		Oregon	
Pennsylvania		South Carolina[3]	
Rhode Island[1]		Nebraska	1920
Vermont		Delaware	1921
District of Columbia[2]		Mississippi	
Maryland	1916	New Jersey	
Indiana	1917	Illinois	1922
Kansas		Montana	
Kentucky		Wyoming	
North Carolina		Florida	1924
		Iowa	
		North Dakota	

[1] Dropped from the registration area in 1919; readmitted in 1921.
[2] Included in registration States.
[3] Dropped from the registration area in 1925.

Death Rates.—The death rate of the death registration area for 1924 is 11.9 as against 12.3 for the previous year. The record low rate in this table is 11.6 for 1921 and the record high rate 18.1 for 1918, the year of the influenza pandemic.

The following tables show the crude death rates for the registration states and cities of 100,000 popula-

BIRTH REGISTRATION AREA: 1915-1924

Year	Birth Registration Area								
	Population[1]		Land Area		Births[2]		Deaths		Deaths of Infants Under 1 Year of Age Per 1,000 Births
	Number	Per Cent. of United States Total	Square Miles	Per Cent. of United States Total	Number	Rate Per 1,000 Population	Number	Rate Per 1,000 Population	
1915...	30,936,179	31.1	292,860	9.8	776,304	25.1	436,593	14.1	100

[1] Exclusive of stillbirths. [2] Enumerated population, June 1.

tion or more in 1920. Caution should always be exercised in drawing deductions from crude death rates, for due allowance must first be made for deaths of nonresidents and for the peculiar composition of the population as regards age and sex distribution, color and nativity, as well as other factors. The generally high rates for southern cities are due to the large proportion of colored population.

Infant Mortality Rates.—The 1924 infant mortality rate breaks all records for the birth registration area. The infant mortality rate, 71 for 1924, is well below the 1923 rate, 77, and far below the 1915 rate, 100.

DIVISION XXXIV
PHILOSOPHICAL AND SOCIAL SCIENCES

PHILOSOPHY

By Herbert Wallace Schneider
Assistant Editor, "Journal of Philosophy," Columbia University

Scholasticism and Exposition.—Whether or not virtue can be taught, philosophy must be. In this country especially, philosophy is today seldom engaged in out of love for wisdom; it is rather, as Cicero defined it, a *studium*, something taught in our schools. There are, of course numerous men of letters and even an occasional clergyman, who reveal a dominant interest in wisdom and an intelligent pursuit of it, but these men do not profess to be philosophers, and the professors of philosophy in turn avoid all who are not members of the acadėmic guilds. The professional philosophers, however, do not earn their living by pursuing philosophy, but by teaching it.

Happily these two functions are not entirely distinct. Scholasticism has in all ages encouraged systematized and consistent expositions of philosophies, and the expounder may at the same time be an inquirer. But on the other hand, scholasticism has always exerted a narrowing influence in that it has encouraged systems, labels, artificial terminologies, and protracted logomachies. American professors of philosophy appear to be gradually freeing themselves of this tradition, but the process is naturally slow, for academic walls are very thick.

New Texts.—This year has witnessed an unusual number of texts designed to "introduce" students to philosophy. Professors G. T. W. Patrick, G. Watts Cunningham, G. P. Conger, James H. Regan and C. W. Brightman have each written an *Introduction to Philosophy.* These texts are symptomatic of the dominantly pedagogical and scholastic approach to philosophy, but at the same time, compared with former texts, they signify considerable progress in the direction of understanding and criticising various philosophies. There is still the natural effect which every genuine philosopher always gives of introducing students to his own philosophy and of regarding all others as if precisely designed to culminate in this one. And even where the author's philosophership is subordinated to his professorship, and the panorama of philosophies is hence conceived more objectively, there is the old tendency to regard them all as parts of one dialectical whole, or at least of a single "evolution of thought." Nevertheless these texts are not only less formal and academic than their predecessors, but also more useful as academic introductions, in that they are calculated to stimulate the interest and reflection of the student rather than to settle his mind once and for all.

Logic. — The introductory *Logic* courses in most of our colleges have also borne their annual fruit: Professors H. E. Cunningham, D. S. Robinson and M. T. McClure have written elementary texts for college courses in logic. The last named of these makes a significant departure in the direction of emphasizing the process of thinking and its guidance in place of the more traditional emphasis on the laws and structure of proof and argument.

Growth in Research.—Among the current evidences that our university philosophy departments are devoting themselves more explicitly to research and less to the composing of courses and texts, should be mentioned the work of the Philosophical Union of the University of California. It has not only engaged in a number of coöperative inquiries into fundamental problems, but has secured the assistance of eminent scholars from other universities, and the results have been published in a series of volumes. Volume VII, published this year, is entitled, *Studies in the Problem of Norms, University of California Publications in Philosophy, Volume 7*, and contains lectures by Professors Adams, Lengen, Prall, Pepper, Parker, Loewenberg, and Montague. Present and former members of the Department of Philosophy of Columbia University, have published Volume II of their *Studies in the History of Ideas*, in which are published a number of significant researches from the historical point of view.

Kant Anniversary.—The years 1924 and 1925 have been the occasion of celebrating the two-hundredth anniversary of Kant. A large meeting was held for this purpose at Boston, April, 1924, and the results published. The meetings of the Philosophical Association, and the various journals have brought out a large number of "*Kant Studien.*" Number Two of this year's Monist is devoted entirely to Kant.

Creighton.—The deaths of Professors Fullerton and Creighton mark the passing of two of the most distinguished of the philosophers of the older generation. Professor Creighton was one of the greatest leaders of philosophical thought in this country and very influential as one of the founders of the Philosophical Association, and of the *Philosophical Review.* It was therefore only fitting that considerable attention should be paid to him during the year. The Eastern Division of the Philosophical Association held a memorial meeting and the Western Division took this occasion to devote its session in April to the philosophies of Bradley, Bosanquet and Creighton. A collection of Creighton's philosophical studies together with a bibliography has been edited by Professor Smart and Professor Hammond, and published under the title, *Studies in Speculative Philosophy.*

Carus Foundation.—Probably the most significant philosophical event of the year was the publication of the first lectures on the Paul Carus Foundation. This foundation is in itself an important institution, which may be expected to offer the needed encouragement and opportunity for the very finest type of scholarship, and the first volume, John Dewey's *Experience and Nature*, is therefore doubly significant.

Dewey.—This book represents the broadest and most searching expression which Professor Dewey has yet given to his "critical radical empiricism." It is definitely an attempt to develop his analysis of experience, which has traditionally had an idealistic background, upon a naturalistic basis, and it employs the results of anthropological and historical sciences, rather than of traditional psychology and epistemology in distinguishing the various phases and types of human experience and the effects of their variations upon such fundamental concepts as nature, means and ends, purpose, value, art and science. It is especially thorough-going in its attempt to prove that the eulogistic implications of the concepts of universals and the super-empirical have traditionally linked them with ends, whereas empirically they are means, the ends being particular and individual. Hitherto Professor Dewey had emphasized the implications of this thesis for the problem of knowledge; here he emphasizes its implications for the more catholic problems and fundamental categories of philosophic thought.

Santayana.—Two other important philosophies have received classic expressions during the year. Santayana's *Dialogues in Limbo*, though they are in substance merely a further exposition of the philosophy outlined in *Scepticism and Animal Faith*, are an unusually beautiful composition, even compared with Santayana's other writings, and are unusually rich in historical criticism, imagination and practical wisdom. The ironical treatment given to scepticism in the former volume, yields in this one to a poetic treatment of "animal faith," here termed "normal madness."

Whitehead.—Professor Whitehead, who is at least temporarily a member of the American fraternity of philosophers, has given to his own and in general to the contemporary British variety of realism a new and dignified expression in his *Science and the Modern World.* In this volume he attempts to show the effects of the varieties of scientific method not only on philosophy but on the larger reaches of the imagination, and he attempts to predict the revolutionary consequences for thought and imagination which are implied in the recent developments of mathematical analysis.

Psychologic.—This year has been particularly fertile in producing typical and comprehensive analyses of mind. Professor E. A. Singer's *Mind as Behaviour,* is an original reconstruction of idealism on a behaviouristic basis, which is significant not merely for it suggestiveness as a fresh analysis of mind, but for its indications of a new direction which "empirical" idealism seems to be taking, and which makes an interesting foil to the "speculative" idealism of Creighton. Both Creighton and Singer realized the futilities of the old psychology, but Creighton turned to the old Logic, whereas Singer turns to the new psychology. G. W. Cunningham's *Five Lectures on the Mind,* from the point of view of a modified idealism, W. P. Montague's *The Ways of Knowing,* from the point of view of a "neo-realist," and Durant Drake's *Mind and Its Place in Nature,* from the point of view of a "critical realist," form an impressive Symposium. There seems to be a general desire on all hands to avoid the dualistic position, and probably all these authors would agree with Professor Drake, when he says: "The differentiation of the mental does not lie in its substance; mental states or events, are made of just the common substance of all things. The differentiation of the mental lies in the concrete relations which link this coördinated system of processes to the things or events that stimulate them, and to the further bodily processes which they evoke." But in the positive problem of analysing these "relations" and "processes" there is still a bewildering variety of opinion. The discussion about perception carried on in the *Journal of Philosophy* by Professors C. A. Strong and W. P. Montague should also be mentioned in this connection.

Behaviourism. — The discussion of behaviourism has continued, but attention has been directed not so much to the problems of psychological methodology as to the implications of behaviourism for such concepts as purpose and mechanism. The Symposium on "Time" at the December meeting of the Eastern Division of the American Philosophical Association is further evidence of the growth of interest in a fresh analysis of fundamental categories.

Value.—The discussions on Value, and particularly Professor Dewey's articles on Value in the *Philosophical Review,* and the *Journal of Philosophy,* represent the "tag end," presumably of a protracted discussion and of an even more protracted preoccupation with the problem of value.

In the field of ethical theory the most important contributions have been: M. C. Otto, *Things and Ideals;* Warner Fite, *Moral Philosophy* (following up the analysis of self-consciousness started in his *Individualism,* 1911); Norman Wilde, *The Ethical Basis of the State;* and W. K. Wright, *The Moral Standards of Democracy.* Professor Eaton of Harvard has made an important and original adventure into the new developments of logic by his *Symbolism and Truth.* Professor Smart's *The Philosophical Presuppositions of Mathematical Logic,* is interesting as an evaluation of the newer symbolic logic by a representative of the idealistic logic.

Select References. — *The International Library of Philosophy, Psychology and Scientific Method,* which is being published by Harcourt, Brace and Company, and which represents a notable advance in philosophical literature in this country, is to be congratulated, if for no other reason, for the new edition of F. A. Lange's *The History of Materialism.* After it, the most important new editions are H. M. Kallen's volume of selections from the writings of William James, with an excellent Introduction (*Modern Library Series*), and Ralph Barton Perry's new edition of Weber's *Philosophy of History,* with additional chapters of his own on recent developments.

Among the historical studies published this year, the most important are the following: George Boas, *French Philosophies of the Romantic Period;* E. A. Burtt, *The Metaphysical Foundations of Modern Science;* W. C. Stace, *The Philosophy of Hegel;* C. W. Hendel, *Studies in the Philosophy of Hume;* J. H. Randall, Jr., *The Growth of the Modern Mind;* and A. Wolf, *The Philosophy of Nietzsche.*

The most important philosophical periodicals published during the year are: *The Philosophical Review, The Journal of Philosophy, The Monist,* and *The International Journal of Ethics.*

In 1924 the Pacific Division of the American Philosophical Association was organized and held its first meeting at the University of California. Professor H. W. Stuart was elected President. The 1925 meeting was held at Stanford University, November 27 and 28. The 1924 meeting of the Eastern Division was held at Swarthmore College, and was presided over by Alexander Meiklejohn. The 1925 meeting was held at Smith College, Professor Wilbur M. Urban, being president.

PSYCHOLOGY

By Herbert Sidney Langfeld

Director, Psychological Laboratory, Princeton University

General.—There have been several encouraging signs of progress in experimental psychology this past year. An Institute of Psychology devoted to research has been started at Yale University. This Institute is in addition to the Psychological Laboratory. R. M. Yerkes, R. Dodge and C. Wissler, together with H. C. Bingham, constitute the staff. Dodge is conducting experiments on eye movements and on physiological changes. Yerkes is working on the primates, and Wissler is engaged in anthropological investigation. The first independent psychological laboratory in the western hemisphere, planned exclusively for teaching and research, has been erected at Princeton University. At its inauguration in April, E. B. Titchener gave an address entitled *Experimental Psychology; A Retrospect* (*Am. Jour. Psych.,* July, 1925). At Clark University the G. Stanley Hall Professorship in Genetic Psychology has been established, and W. S. Hunter has been appointed the first incumbent. At the December meeting of the American Psychological Association papers in memory of G. Stanley Hall were read by W. H. Burnham "The Man, G. Stanley Hall" (*Psych. Rev.,* March, 1925), and by E. D. Starbuck "G. Stanley Hall as a Psychologist" (*Ibid.*).

Theoretical. — The *Gestalt* theory or as it is commonly translated, the "Configuration" theory, has received prominence in America through the visit of Wolfgang Köhler, director of the Psychological Laboratory of the University of Berlin, and Kurt Koffka of the University of Giessen. Köhler's book, *The Mentality of Apes*" (Harcourt, Brace, 1925), and Koffka's *The Growth of the Mind* (*Ibid.*) have recently been translated from the German. The theory, which they have been describing in numerous lectures throughout the country, states that we perceive objects, relations, and situations and then proceed to analyze them, and that these perceptions are something more than the mere summation of their parts or elements. A number of psychologists in America, inspired by these authors, have recently written articles upon this theory.

Helson's description of the *Psychology of Gestalt* is the most complete (*Am. Jour. Psych.*, July-Oct., 1925). A number of new textbooks have appeared this last year. J. B. Watson's *Behaviorism* (The People's Institute Printing Co.), which is based upon the lectures which he gave before the People's Institute, is somewhat more radically behavioristic than his last book. M. Bentley's *The Field of Psychology* (Appleton, 1925), covers the field of individual, social, and genetic psychology, and incorporates both the old and the newest doctrines in psychology. H. C. Carr's *Psychology* (Longmans, Green, 1925), is a careful study along rather traditional lines. T. V. Moore's *Dynamic Psychology* (Lippincott, 1925), aims to impart a practical understanding of the inner life and mental difficulties. Behaviorism, which was first made popular in America by J. B. Watson, continues to have a very strong influence.

W. S. Hunter, who is a conservative adherent to the theory, has proposed a new term for the study which deals with human nature as contrasted with the study of mind, "General Anthroponomy and Its Systematic Problems" (*Am. Jour. Psych.*, April, 1925). C. Rosenow believes that a mechanistic behaviorism cannot deal with mind. *The Problem of Meaning in Behaviorism* (*Ibid.*).

H. C. Warren has described *Mechanism and Teleology in Psychology* (*Psych. Rev.*, July, 1925). E. C. Tolman, who has always been a very constructive behaviorist, has a paper upon *Purpose and Cognition; The Determiners of Animal Learning* (*Ibid.*). J. E. Dashiell has offered *A Physiological-Behavioristic Description of Thinking* (*Ibid.*, Jan., 1925), and J. E. Markey has described *The Place of Language Habits in a Behavioristic Explanation of Consciousness* (*Ibid.*, Sept., 1925). A. P. Weiss has expounded his views of behaviorism in his new book entitled *A Theoretical Basis of Human Behavior* (R. G. Adams, 1925). L. Carmichael has criticised and evaluated Titchener's and McDougall's doctrines; *An Evaluation of Current Sensationalism* (*Psych. Rev.*, May, 1925). Partly through the interest in behavioristic psychology, a number of experimenters have worked upon the conditioned reflex. H. Cason has described *The Physiological Basis of the Conditioned Reflex* (*Am. Jour. Psych.*, July, 1925). G. Humphreys asks the question, *Is the Conditioned Reflex the Unit of Habit?* (*Jour. Abnorm. and Soc. Psych.*, April, 1925). J. L. Mursell contends that nutrition is a psychological factor in life as significant as sex; *Contributions to the Psychology of Nutrition* (*Psych. Rev.*, July, Sept., Nov., 1925).

Experimental Methods.—There are indications from the literature that the interest of psychologists is being directed away from the so-called sensations to perceptions, emotions, and the higher mental processes. Reflexes and habit formations are also frequent subjects for investigation. H. E. Burtt and W. W. Tuttle have found that unpleasant words when repeated to an individual at the time of stimulating the patellar tendon depressed the reflex more than do pleasant words. *The Patellar Tendon Reflex and Affective Tone* (*Am. Jour. Psych.*, Oct., 1925). A. M. Thorsen has made a behavioristic study of *The Relation of Tongue Movements to Internal Speech* (*Jour. Exp. Psych.*, Feb., 1925). D. Weschler's paper on *The Measurement of Emotional Reactions; Researches on the Psycho-Galvanic Reflex* (*Arch. of Psych.*, No. 76, 1925) is especially valuable for the technique described. H. K. Nixon showed by a series of questions how many erroneous beliefs are held by educated persons; *Answers to Certain Psychological Questions* (*Am. Jour. Psych.*, July, 1925). A number of papers deal with the emotional life. V. Conklin and F. L. Dimmick have made *An Experimental Study of "Fear"* (*Ibid.*, Jan., 1925). W. F. Blatz has made an extensive study of *The Cardiac, Respiratory, and Electrical Phenomena Involved in the Emotion of Fear* (*Jour. Exp. Psych.*, April, 1925). E. Totten discovered in six out of fourteen cases an increase in oxygen consumption following emotional stimulation; *Oxygen Consumption During Emo-*

tional Stimulation (*Comp. Psych. Mon.*, No. 13, 1925).

A number of investigations are closely associated with æsthetic problems. M. Monroe has shown that colors seem to have weight, which influences our arrangement of them; *The Apparent Weight of Colors, and Correlated Phenomena* (*Am. Jour. Psych.*, April, 1925). H. K. Mull has proven that contrary to the idea that absolute pitch is innate, the average person can acquire absolute pitch through practice; *The Acquisition of Absolute Pitch* (*Ibid.*, Oct., 1925). K. Gordon has investigated the correlation between memory and pleasant and unpleasant odors; *The Relation of Pleasant and Unpleasant Odors* (*Jour. Exp. Psych.*, June, 1925). E. B. Skaggs has made a further study in *Retroactive Inhibition* (*Psych. Mon.*, No. 161, 1925), in which he found that it is better to rest after a period of learning than to engage immediately upon some other strenuous work. D. Stumberg in an experiment on the detection of deception made *A Comparison of Sophisticated and Naïve Subjects by the Association-Reaction Method* (*Am. Jour. Psych.*, Jan., 1925). H. F. Whiting and H. B. English found that fatigue did not directly cause decrease in work; *Fatigue Tests and Incentives* (*Jour. Exp. Psych.*, Feb., 1925). E. A. Bott on the basis of experiments has formulated *The Law of Orientation in Stereoscopy* (*Ibid.*, Aug., 1925). R. M. Dorcus has found that increased blood pressure and pulse rate are due to tobacco and not to suggestion (*Effect of Suggestion and Tobacco on Pulse Rate and Blood Pressure, Ibid.*, Aug., 1925). E. J. Swift and J. A. McGoech have found that periods of time, at least up to five minutes, whether filled or empty, are under-estimated by both men and women; *An Experimental Study of the Perception of Filled and Empty Time* (*Ibid.*, June, 1925). W. R. Miles and Eugene Shen found that vertical reading was not less efficient than horizontal; *Photographic Recording of Eye Movements in the Reading of Chinese in Vertical and Horizontal Axes; Method and Preliminary Results* (*Ibid.*, Oct., 1925). In the field of sensation C. E. Ferree and G. Rand have contributed three more studies on the problems of photometry (*Am. Jour. Psych.*, April, 1925).

Study of the Abnormal.—The American and European friends of Morton Prince have contributed to a volume on *Problems of Personality* (Harcourt, Brace, 1925), in honor of his 70th birthday. The articles for the most part deal with the subconscious mechanism. Morton Prince himself has given a further description of his theory of the subconscious in an article entitled *Automatic Writing Combined with Crystal Gazing* (*Jour. Abnorm. and Soc. Psych.*, April, 1925). William McDougall approves of Freud's adoption of the hormic principle. He considers it a great advance for the Freudian psychology (*Ibid.*). J. Slawson has indicated the general trend of the *Psycho-neurotic Response of Delinquent Boys* (*Ibid.*, Oct., 1925). P. C. Young has found that there are practically no observable differences between the normal and hypnotic states in regard to sensing, perceiving, discriminating, memorizing, and physical work not involving fatigue (*Am. Jour. Psych.*, April, 1925). L. E. Bisch's *Clinical Psychology* may be useful to social workers, as it gives an idea of amentia, epilepsy, and psychopathic states, and describes procedure in neurological clinics (Williams & Wilkins, 1925). A. Myerson, who has had considerable experience in clinical work, has just published a book entitled *The Inheritance of Mental Diseases* (Williams & Wilkins, 1925).

Animal Study.—There has been this year increased interest in the experiments on infra-human organisms. D. Moseley in an article on the *Accuracy of the Pecking Response in Chicks* (*Jour. Comp. Psych.*, Feb., 1925), states that there is accuracy in pecking from the first, but that the chick has to learn to seize the food. C. P. Stone has found that there is a change in sex habits due to change in diet; *Delay in the Awakening of Copulatory Ability in the Male Albino Rat, Incurred by Defective Diet* (*Ibid.*, April, 1925). C. F. Sams and E. C. Tolman have found that rats can discriminate between one minute and six minute intervals of time; *Time Discrimination in White Rats* (*Ibid.*, June, 1925).

Social Study.—C. H. Judd has given a psychological interpretation of social institutions; *Psychological Bases of Social Studies* (Macmillan, 1925). K. Dunlap has just published a new *Social Psychology* (Williams & Wilkins, 1925). R. S. Woodworth (*Jour. Abnorm. and Soc. Psych.*, April, 1925), has written a comprehensive and appreciative review of F. H. Allport's important *Social Psychology* (Houghton, Mifflin, 1924). G. M. Lowe and M. E. Stumberg do not believe that moral judgments are reliable indications of moral integrity; *A Critique of Fables as a Moral Judgment Test* (*Jour. Applied Psych.*, March, 1925). T. H. Lund has made an empirical investigation of *The Psychology of Belief* in which he found that belief is largely conditioned by emotional states (*Jour. Abnorm. and Soc. Psych.*, July, 1925). J. H. Leuba has made another valuable contribution to the psychology of religion in his *The Psychology of Religious Mysticism* (Harcourt, Brace, 1925). H. T. Moore, on the basis of experiments on college students, believes there are *Innate Factors in Radicalism and Conservatism* (*Jour. Abnorm. and Soc. Psych.*, Oct., 1925). T. C. Paschal and L. R. Sullivan have described the *Racial Influences in the Mental and Physical Development of Mexican Children* (*Comp. Psych. Monthly*, Oct., 1925). They found that skin color shows the highest correlation with mental scores.

Applied Psychology.—H. E. Burtt and E. M. Dobell have described the *Curve of Forgetting for Advertising Material* (*Jour. Applied Psych.*, March, 1925). J. L. Holmes has used the *Free Association Method as a Measure of the Efficiency of Advertising* (*Ibid.*, June, 1925). G. Brammer has investigated *The Static Equilibrium of Airplane Pilots* (*Jour. Comp. Psych.*, Oct., 1925). M. Schoen has devised *Tests of Musical Feeling and Musical Understanding* somewhat after the manner of the Seashore Tests (*Ibid.*, Feb., 1925). G. C. Brandenburg believes it possible to determine the relations of various characteristics of personality and the relative importance of traits for success in different vocations (*Analyzing Personality, Jour. Applied Psych.*, June, 1925; *Personality and Vocational Achievement, Ibid.*, Sept., 1925).

Educational.—Mental tests continue to be the chief topic of interest in educational psychology. The College Entrance Examinations Board has appointed a committee of psychologists with C. C. Brigham as chairman, to devise tests for college students. W. E. Bagley's new book is entitled *Determinism in Education* (Warwick & York, 1925). W. Stern has described the child's life from birth to the sixth year in *Psychology of Early Childhood* (Holt, 1925). W. B. Pillsbury's book is entitled *Education as the Psychologist Sees It* (Macmillan, 1925). L. R. Marston has made a study of introversions and extraversions in children: *The Emotions of Young Children* (University of Iowa Studies, No. 95, June, 1925). L. C. Wagener states that the constructive ability in young children is not a function of intelligence. It appears to be a special ability. *The Constructive Ability of Young Children* (*Ibid.*, No. 94, June, 1925). R. M. Ogden has incorporated the *Gestalt* theory in his idea of *The Nature of Intelligence* (*Jour. Ed. Psych.*, Sept., 1925). C. Spearman has challenged E. L. Thorndike to an experimental verification of the factor theory of intelligence (*Ibid.*). L. L. Thurstone has described *A Method of Scoring Psychological and Educational Tests* (*Ibid.*, Oct., 1925). W. F. Hyde and J. R. Gilford were able to eliminate two-thirds of the failures in chemistry by *A Test for Classification of Students in Chemistry* (*Jour. Applied Psych.*, June, 1925). A. T. Poffenberger states that the higher a man stands in college the greater chance he has of succeeding in after life; *School Achievement and Success in Life*; (*Jour. Applied Psych.*, March, 1925). J. A. McGoech found in normal intelligent children no direct relation between intelligence and their fidelity in reporting what they had experienced (*Am. Jour. Psych.*, July, 1925). I. Carmichael has made *A Study of a Case of Mirror Writing,* and gives an explanation of this abnormal phenomenon (*Studies in Ed. Psych. and Ed. Measurement*, 1925).

ANTHROPOLOGY AND ETHNOLOGY

By George Grant MacCurdy

Professor at Yale University

A survey of progress in the anthropologic sciences admits of geographic treatment. Since the earliest stages in cultural and physical evolution of man are found in the Old World, we shall cover that field first.

EUROPE

France.—Dr. E. Passemard reports the discovery of ancient crude flint artifacts on the left bank of the Adour river in the section known as La Chalosse (Landes), southern France; this discovery was made by P. Dubalen with whom Passemard later collaborated. It affords additional evidence in support of the existence of a Pleistocene industry antedating the Chellean Epoch; it is generally referred to as Pre-Chellean. The deposits in which the very old crude implements are found rest on yellow sands of the Lower Pliocene. Above the pebbly layer containing the crude implements there is a relic-bearing deposit with three artifact levels: Challean, Acheulian, and Mousterian respectively. The whole is capped by vegetal earth with objects dating from the Neolithic and later. Most of the implements from the Pre-Chellean horizon are fashioned from Senonian flint nodules or large flakes of the same flint; a few however, are from quartzite pebbles.

The Dordogne continues to yield rare examples of Paleolithic art. Two fine figures in relief of the wild ox (*Bos primigenius*) on stone have just been published by Capitan and Peyrony. The legs and ventral portion of one figure are hidden behind the body of the other beast, of which the observer has an unobstructed view. In other words, the artist has deftly rendered the profile of two oxen standing side by side as they would appear to a beholder in a more elevated position. The figures have been referred to a late phase of the Solutrean Epoch.

Switzerland.—Since 1923 Dr. Emil Bächler has explored Wildenmannlisloch, a cavern in the canton of St. Gallen on the northern slopes of the Churfirsten, at an elevation of 1600 meters (5,253 feet), above the sea. Culturally and chronologically, as well as geographically, Wildenmannlisloch links Wildkirchli with Drachenloch. It lies some 20 kilometers (12.5 miles) southwesterly from the Ebenalp (Wildkirchli) from which it can be reached by way of the Rotsteinpass, and some 30 kilometers (18.75 miles) northwesterly from Drachenloch. The stone and bone industry as well as the fauna resemble the fauna and industry from Wildkirchli and Drachenloch. Remains are found at two successive occupation levels which are intercalated between two glacial deposits of clay—Riss below and Würm above. The Würm clay is capped by a postglacial deposit. The leading fossils of the lower occupation level are cave bear and cave lion; the red deer makes its appearance at the top of the upper level.

As at Wildkirchli and Drachenloch, the socket of the cave bear hip bone was used as a vessel after the removal of the iliac, ischiac, and pubic portions; use was also made of the proximal end of the cave bear fibula as a tool.

One of the finds at Wildenmannlisloch may serve to throw light on how man first came to be an artist. There is now a good deal of cumulative evidence pointing to the influence of fortuitous resemblances in nature to animal forms as bearing on primitive man's nascent artistic bent. Once detected, natural effigies would be gathered and treasured, and means would eventually be found to supplement and improve on nature's haphazard creations. The specimen in question from Wildenmannlisloch consists of a piece of lower jaw of the cave bear which bears a striking resemblance to a human head and body; the concavity of the socket that held the canine forms the neck and chin. The piece bears evidence of a considerable amount of wear as if it had been carried as a fetich.

In 1924 Professor O. Tschumi discovered at Moosbühl near Bern, an important loess station with Magdalenian hearths at a depth of 40 centimeters (15.7 inches). This level has yielded a typical industry including combination scratcher-gravers blades with back worked down, small nuclei (all of flint) and bone points. Above the Magdalenian level, Tschumi found vestiges of a Neolithic and a Roman occupation. Moosbühl lies close to the line representing the maximum extension of the Würm glaciation and is nearer to the heart of the Alps than any other Magdalenian station yet discovered; it probably belongs to the closing phase of the Magdalenian coincident with a much restricted area of Alpine Würm glaciation.

Czechoslovakia.—One of the outstanding Paleolithic discoveries of the past summer is that reported by Dr. K. Absolon. It is a great loess station on the northern slope of Palavske mountain near the village of Dolni Vistonice (Unter Wisternitz). The site is near the southern frontier of Czechoslovakia, about midway between Brünn and Vienna; it covers a considerable area and is rich in relics of the Aurignacian Epoch. The most important specimen discovered is an indurated clay figurine representing the human female and belonging to the so-called Venus type. The Dolni Venus is a cross between the Willendorf Venus of stone found some twenty years ago in the Danube valley only a short distance to the west, and the Lespugue Venus of ivory found in 1922 in southern France (Haute-Garonne).

Other clay figures discovered at Dolni Vistonice include that of a human hip and leg, and a bear; there is also the figure of a young mammoth carved out of a so-called *loess poupée* or concretion. The four legs stand out free from the body; the stump of the broken trunk had been polished by use. The *poupées* of the recent loess are always small, so that this figure of the mammoth measures only 2.6 centimeters (1 inch) by 2.1 cm. high. In addition the site has already yielded many implements of flint and stone, also the upper portion of a human cranium prepared for use as a vessel, not unlike those found some years ago in the cave of Placard (Charente), France and numerous skeletal remains of the mammoth.

Russia.—The discovery of fossil human remains has been reported from the Crimea. The rock shelter (or cave) known locally as Kik-Koba is near the village of Kiptchak, about 25 kilometers (15.6 miles) east of Simferopol. A section reveals two relic-bearing horizons separated by an almost sterile deposit of yellow clay. The lower deposit has yielded some 200 flint implements, 3,000 flint chips, two human skeletons (adult and child), and fossil animal remains: mammoth, woolly rhinoceros, saiga antelope, giant deer, bison, horse, fox, etc. The human adult skeleton is said to be of the Neanderthal type.

The upper horizon is likewise rich in artifacts and fossil animal remains: giant deer, saiga antelope, and red deer. The fauna from both horizons is obviously of Pleistocene age; the cultural remains are probably Mousterian. Whether the human skeletal remains are as old as the deposit, or intrusive and of later date, is apparently not yet fully determined.

Dr. R. Saller has reported the discovery of the upper front portion of a human cranium in a loess deposit at Podkumok in the Crimea. The fragment might be described as belonging to an attenuated Neandertal type and is probably of Aurignacian age.

ASIA AND AFRICA

Asia.—Our knowledge of the ancient habitat, or geographic range, of Neanderthal man is gradually widening. The British School of Archeology in Jerusalem has just reported the discovery of a frontal bone of the Mousterian or Neanderthal type in "Mugharet el Zuttiyje" or Robber's Cave near Tabgha, some six miles northwest of Tiberias. The big brow ridges and the low forehead, as well as the associated artifacts, leave no doubt as to the Mousterian age of the specimen in question.

Père E. Licent and P. Teilhard de Chardin have found indubitable traces of Pleistocene man to the south of the Ordos over an extent of some 200 kilometers (125 miles) in length. They mention three localities: the basin of the Choei-tong-k'eou near Ning-hia-ofu; the banks of the Sjara-osso-gol, south of the Ordos; and the grand loess in the vicinity of Yu-lin-fou.

In the Choei-tong-k'eou basin there is a distinct habitation level in the loess as well as isolated specimens so distributed as to show that throughout the period of loess formation man lived in this region. The first discovery (1920) included the skull of a woolly rhinoceros in association with a chipped implement of quartzite. The artifacts, for the most part of quartzite, are very numerous. Fossil animal remains found in the kitchen refuse include: wild ass, wild ox, gazelle, woolly rhinoceros, and hyena.

The Sjara-osso-gol, an affluent of the Hoang-ho, descends from the loess mountains of the Chensi and traverses the southeast angle of the Ordos, where it forms a canyon in some places 70 meters (230 feet) deep. As at Choei-tong-k'eou, so also in the basin of the Sjara-osso-gol, man had lived on an old land surface and there left his artifacts and kitchen refuse. In the latter, while the artifacts are rare and of small size, the fauna is very rich. No human skeletal remains were encountered in either locality. At Sjara-osso-gol the animal remains are remarkably well fossilized. The species comprise: elephant, woolly rhinoceros, wild ass, wild ox, giant deer, wolf, cave hyena, badger, *Arvicola*, etc.

To the south of the Ordos a great loess mantle spreads across Chensi and Kansu, in some places attaining a thickness of 150 meters (492 feet). This grand loess mantle is contemporaneous with and geographically near to the deposits of Sjara-osso-gol and Choei-tong-k'eou. Near the base of the grand loess, Licent and Teilhard found implements of quartzite at You-fang-t'eou to the south of Yu-lin-fou. These implements are thought to be the same age as those found in the basins of Choei-tong-k'eou and Sjara-osso-gol. The conclusion is that man lived contemporaneously in all three of these localities with the Mousterians, and perhaps the early Aurignacians, of Europe.

A flint blade retouched on the margins of one face only, found at Skotovo near Vladivostock, has just been published by Breuil, who refers to it as representing a culture equivalent to the European Aurignacian. Skotovo lies some 2,000 kilometers (1,250 miles) northeasterly from the Ordos in northern China.

Africa.—A discovery of prime importance in the realm of fossil primates was announced early in the year by Professor Raymond Dart of Witwatersrand University at Johannesburg. The specimen in question is the almost complete skull of a young individual of about four years, representing either an anthropoid or a form intermediate between living anthropoids and man. Whether it be a fossil chimpanzee or a fossil link connecting anthropoids with man, the value of this specimen is great because of its completeness. One's first impression from casts and illustrations is that it is more humanoid than anthropoid. Both the face and cranium are long, producing a harmonious whole; the nasal region seems to be distinctly anthropoid. On the other hand there are characters of both skull and brain which border on the humanoid. The endocranial cast is so well preserved as to admit of interesting observations leading Professor G. Elliot Smith to conclude that the skull belonged to an ape whose brain points the way toward the human brain.

The specimen was taken from a

cave in a calcareous formation near Taungs, some 128 kilometers (80 miles) north of Kimberley. It is known as the Taungs skull. According to R. Broom, the deposit in which it was found is of Pleistocene age. If this be true, the value of the skull as representing a type ancestral to both man and the higher apes, is appreciably diminished.

Dr. A. Hrdlicka of the United States National Museum, just returned from a six months' survey in the Far East and Africa connected with man's origin and evolution, reports that the Taungs region and the Broken Hill country of South Africa both offer immense possibilities in throwing light on human origins; the two other regions mentioned by Dr. Hrdlicka as offering unusual opportunities for anthropologic research are the Siwalik Hills of India and the valley of the Solo River in Java.

Polynesia.—During 1925 the Bernice P. Bishop Museum, under the direction of Professor H. E. Gregory, continued its study of the Polynesians with particular reference to origins, routes of migration, and early history. Field parties have been at work in the Society Islands, Samoa, and the Tuamotus. Preliminary surveys were made also in Tirian, Rota, and Saipan of the Marianas Islands. Members of the Museum staff resident in Honolulu devoted their time to investigations based on the results of the Tanager expedition, the Whippoorwill expedition, and the cruise of the Kaimiloa. During the year six bulletins relating to Pacific ethnology were published.

UNITED STATES

Indian Languages.—Professor Edward Sapir of the University of Chicago is convinced of the identity of the language of certain Indian tribes with that of the primitive Chinese. By a close comparison of the primitive Chinese, Siamese, and Tibetan, all in the same language category, with the "Nadine group" of North America, he finds the same peculiarities of phonetics, vocabulary, and grammatical structure on both sides of the Pacific Ocean. Dr. Sapir has discovered not only that the Nadine groups speak with a tonal accent, raising or lowering the voice to give certain meaning to words, in a manner similar to the tonal peculiarities of the early Chinese, but also that the meanings of certain words are identical. He has disclosed further that the Indians have retained certain prefixes and suffixes which long ago have disappeared from the Chiese speech, but which are clearly discernible in the early forms. Indians speaking the language of the Nadine group are found in all parts of North America as far south as northern Mexico. This linguistic similarity forms another link in the chain of evidence showing that America was peopled from Asia by way of the Behring Strait.

Connecticut.—Carroll G. Alton of Peabody Museum, Yale University, conducted excavations on the site of the historic Mohegan Indian village located on Shantok Point which overlooks the Thames river, two miles south of Norwich. Several thousand artifacts were secured, some of which are aboriginal, others aboriginal but showing Colonial influence, and still others which are purely trade objects. Of especial interest are numerous bone awls, antler handles, long ribbone needles (highly polished and perforated), a rare bone fishhook, conch columns and fragments showing wampum in all its stages of manufacture, wampum stones, and pottery fragments. A fine collection of trade material was secured which includes many clay pipes, one brass pipe, iron and copper arrowheads, spoons, jews' harps etc. All of the above mentioned specimens were found in association with kitchen refuse consisting of oyster shells and animal bones.

Ohio.—The excavation of the Hopewell group of mounds has been completed and the material moved to the Museum of the State Archeological and Historical Society at Columbus where an entire room is devoted to this group. Director W. C. Mills began the excavation of mound number 2 of the Seip group in the Paint Creek valley, Ross county, the first of August. Before the season was over he brought to light a remarkable burial. The sarcophagus, which had been made of logs, contained three adults and two children and the burials were wrapped in a burial robe with designs painted in color over the whole; these robes had evidently been decorated with pearls from head to foot, the many thousands that were removed showing that they had been attached to the cloth.

The artifacts in the grave were also notable as many objects were made of tortoise shell; one especially interesting was that of a swan, beautifully cut. The burials were accompanied by copper objects of various kinds such as ornaments, large plates, axes, awls, and many objects covered with copper and silver, such as buttons, etc. The most interesting of the objects found were the large pipes made of stone. These pipes, the largest weighing seven and one-fourth pounds, were all effigies—that of the dog, bear, owl, and night hawk. An interesting feature of the finding of the pipes was that they were not placed directly in the sarcophagus, but above it.

Mills has begun the work of converting the Mound City group of mounds into a state park. The park, covering an area of 58 acres and containing some 30 mounds, is the gift of the United States to the Ohio State Archeological and Historical Society.

Southwest.—Mr. Neil M. Judd of the U. S. National Museum has completed his fifth season as director of the National Geographic Society's Pueblo Bonito Expedition. The outstanding feature of the past season's work is the definite establishment of a culture sequence based on the pottery found.

The Department of Archeology of Phillips Academy, Andover, has continued its work at Pecos.

Gran Quivira Pueblo and the Mimbres river valley have been the scene of important excavations under the direction of Dr. E. L. Hewett, director of the School of American Research.

Director C. C. Willoughby of Peabody Museum, Harvard University, reports the discovery of 254 burials in the Mimbres valley of New Mexico. A large collection of pottery vessels and a number of other objects were obtained. The decorations appearing upon the pottery are in general restricted to this area, and include many well drawn figures of birds, quadrupeds, fishes, etc. In northeastern Arizona, explorations were carried on in the Chinlee valley at Rock Point. About thirty small sites were examined. The remains found here seem to represent a transitional stage between the pre-Pueblo and Pueblo cultures. A short time was spent investigating the ruins in Tse-a-chong Canyon, southwest of Carrizo mountains. Several of the kivas, or ceremonial rooms, examined here were in an almost perfect state of preservation.

Nevada.—Among the most important of the recent investigations carried on by the Museum of the American Indian is that which was brought to completion during the year by Mr. M. R. Harrington in certain dry caves near Lovelock. These revealed many interesting objects from a deposit found to be fourteen feet in depth, built up in layers by successive generations of occupancy. The articles recovered indicate that the Indians had been attracted to the spot by reason of the proximity of Humboldt lake. Their chief subsistence was gained from wild plants, rabbits and other small animals, fish and ducks; agriculture was practiced on a small scale. Baskets, textiles, feather headdresses, implements of wood, stone and bone, well-made cordage, fishhooks, fishnets, entire dessicated fish, rabbit snares and decoy ducks are among the objects recovered from the cave deposits. The dead were wrapped with deerskin, with blankets made of muskrat skins, and with fishnets; they were covered with elaborately decorated bowl-shaped baskets made of coiled willows. An adult mummy and the mummy of a child were recovered.

Of at least equal importance was a subsequent research that led to the discovery and beginning of excavation of groups of pre-Pueblo ruins in Clark county, southeastern Nevada, which were scattered over an area several miles long. Many of the ruins lie in the valley, more or less buried in sand-dunes, but others are on the eroded ridges between the lowlands and the mormon mesa. The walls of the houses, averaging seven inches thick, are built of adobe "loaves" laid up with adobe mortar and sometimes interspersed with slabs of stone and the whole plastered with adobe. The floors are usually of adobe, but sometimes are paved with flat sandstone fragments, and, in some houses, slabs are set on edge against the base of the walls. Little of the walls are erect, but with the charred remains of roofs sufficient has been revealed to show that the structures were rectangular, evidently of a single story and with roofs made of poles covered with grass, or tules, and mud. The dwellings consisted of from one to four or five small rooms. Burials were made in the floors of some of the rooms after they were abandoned. Accompanying the dead were earthenware vessels and minor appurtenances.

LATIN AMERICA

Peru.—Dr. A. L. Kroeber, professor of anthropology at the University of California, who was entrusted by the Field Museum, Chicago, with a special mission to Peru for the purpose of determining stratifications of cultures, spent six months in Peru, chiefly excavating in the area from Lima south to Nazca, a stretch of 250 miles. His collection is particularly rich in fine pottery with painted designs, fabrics, and mummy bundles. The results are important and are being prepared for publication by the excavator. His report will be published by the Museum in the beginning of next year.

SELECT REFERENCES

Of the many publications issued during the year, only a few representative ones can be listed:

EBERT, Max (Editor).—*Reallexikon der Vorgeschichte*, Berlin (in several volumes, Vol. I, 1925).

FLESCHE, Francis La.—*The Osage Tribe: The Rite of Vigil, 39th Annual Report, U. S. Bureau of American Ethnology*, pp. 31-636.

GORDON, George B. (Editor).—*Maya Pottery*, University Museum, Philadelphia. One hundred collotype plates nearly all in color.

HOOTON, Ernest A.—*The Ancient Inhabitants of the Canary Islands* (Harvard African Studies, Volume VII, Harvard University Press).

HRDLICKA, A.—*Old Americans—A Scientific Study of the Fathers of America and Their Children* (Williams and Wilkins, Baltimore).

JOCHELSON, Waldemar.—*Archæological Investigations in the Aleutian Islands* (Carnegie Institution).

KEITH, Sir Arthur.—*The Antiquity of Man* (Phila., Lippincott).

KÖHLER, W.—*The Mentality of Apes* (London and New York).

KROEBER, A. L.—*Handbook of the Indians of California* (Bureau of American Ethnology, Bulletin 78).

KUHN, Herbert (Editor)—*Jahrbuch für prähistorische und ethnographische Kunst* (Leipzig).

SAVILLE, M. H.—*The Woodcarver's Art in Ancient Mexico.* Contributions of the Museum of the American Indian, Volume VII, New York.)

STEINEN, Karl von den.—*Die Marquesaner und ihre Kunst*, Vol. I (Berlin, Dietrich Reimer).

SOCIOLOGY

BY HOWARD W. ODUM

PROFESSOR AT THE UNIVERSITY OF NORTH CAROLINA

Current Trends.—A survey of the year's contributions and events in the general field of Sociology indicates certain apparent tendencies. Some of these tendencies, are, of course, summations from the years immediately preceding and most of them are approximate only, but they give substantial evidence of current direction.

There is a decided tendency on the part of sociology to coördinate and correlate its work and research more effectively with the other social sciences and to draw upon them more and more for special data needed in the synthetic study of Society. Examples of this are abundant. One is the representation which Sociology has in the Social Science Research Council, composed of three members from each of the following societies: American Economic Association, American Political Science Association, American Sociological Society, American Statistical Association, American Psychological Association, American Anthropological Association, American Historical Association. Another is the participation of the American Sociological Society in the planning for an encyclopedia of social science and other coördinate efforts for social study and research.

There is, then, the coördinate correlation which comes from a similar attitude of the other social sciences to work more effectively with Sociology. Thus Sociology has tended to increase the variety of its approach to the study of society and the mass of its data until the number of students, teachers, and authors is constantly increasing and the amount of published material is little short of overwhelming. In the midst of this situation there is, therefore, a clearly evolving recognition of the essential problem involved in gathering, evaluating, assimilating and synthesizing this growing mass of new data now everywhere so hopefully and attractively being recruited.

Specialization. — There is fortunately another very definite tendency toward differentiation and specialization to the end that "specialisms" within the field are producing data and method for the scientific study of society such as has not yet been approximated. These specialisms extend to both major divisions of the subject and to concrete segments within these divisions, thus bringing about objective and descriptive studies of greater value and developing more effective method. The year has also brought about the beginnings of the process of integration and correlation, so that the results of the combined present tendencies give promise of a more and more scientific method and more comprehensive results in the whole field of sociology. Some of the examples of specialization and differentiation may be noted.

There is a group which is making special studies in the field of population with increasing emphasis upon the importance of biological factors. Among those are Pearl, Hankins, Huntington, East, Russell, Carr-Saunders, Reuter, Thompson, Woolston, Swinburn, and others. Closely related, and to some extent a part of this group, are those who are making special inquiries concerning the possibilities of race development through birth control, following the earlier beginnings of Ross. Another group including Wisler, Goldenweiser, Boas, Lowie, Huntington, Kroeber, Levy-Bruhl, Faris, Cole and others, have substituted concrete new anthropological materials for old terminologies, and have also contributed much data to the cultural or "superorganic" research and theory represented also by Ogburn, Tozzer, MacCurdy, Willey, Herskovits.

This group has also made important contributions to the current material on race, and along with Hankins and others have offset another group of students of race represented by Stoddard and Grant. There has also been a remarkable renaissance of interest in the Negro and of books dealing with specialized phases of his life and contributions, among which are those by Weatheford, Woofter, Johnson, Odum, Locke, Scarrboro, Kennedy, the Chicago Race Commission, with a half dozen more now in press. In the field of social psychology there has been a notable list including Allport, Bernard, Bogardus, Ellwood, Znaniecki and Williams.

The emphasis upon Sociology for teachers has produced volumes by Snedden and Peters and has resulted in a special group in the American Sociological Society annual meeting. Contributions to the study of the community begun by Hart, Lindeman, McKeever have been greatly augmented by Steiner, Bowman, Follett, McClanahan, and others. In the field of social work Gillen, Steiner, Tufts, Eliot, Abbott, Breckenridge, Queen and others have added important works, while to the study of social problems Parson, Beach, Baker-Crothers, Hudnut, Dow and others have added volumes, exclusive of more elementary texts by Ross, Hart, Keller, Marshall, and a score of studies of citizenship. In the field of history, theory and method, excellent contributions have been made by Giddings, Barnes, Chaddock, Small, Hankins, Chapin, Thomas, Douglas, Spykman. There has been, finally, an increasing number of volumes on general "sociological" subjects and on evolution and religion, many of which have come within the field of sociology.

Research.—An important tendency has been that which emphasizes social research, in which the American Sociological Society has taken an important part. Definite divisions of the annual meeting have been devoted to reports on research problems, projects and methods, while during the year the Society has kept the emphasis constantly upon recruiting personnel, reports, and materials. There has been a large increase in the number of university groups which are devoting themselves to social research. Among the new special Institutes for Research or other special organized efforts for research in which sociological problems are attacked are those at Chicago, Columbia, Harvard, The Robert Brookings Graduate School, North Carolina, Yale, Brown, Iowa and Minnesota. Of special importance in this respect are the fellowship for mature research students offered by the Social Science Research Council through a grant from the Laura Spelman Rockefeller Memorial and those of the Guggenheim Foundation. During the year a total of approximately one hundred such fellowships will be available. Other special efforts and conferences have been held, such as those promoted by the Commonwealth Fund for the consideration of the social studies. Important grants and experiments have been made by the Memorial and Commonwealth Funds for child welfare and public welfare, and other aspects of social work, in many cases having the first steps based upon research and study.

LITERATURE

Periodicals.—One of the most encouraging, and yet most baffling of the year's developments, has been the increase of articles dealing with social subjects and appearing in popular periodicals and scientific periodicals. The *American Journal of Sociology* abstracted during the calendar year some four hundred and seventy articles, selected from 115 periodicals of which 25 were foreign, in addition to more than a hundred additional articles in the popular periodicals. The main classification is the general headings of: Personality; The Family; Peoples and Cultural Groups; Conflict and Accommodation Groups; Communities and Territorial Groups; Social Institutions; Social Science and the Social Process; Social Pathology; Methods of investigation; and General Sociology and Methodology of the Social Sciences. This large volume of "sociological" discussion is evidence of the need for sociologists to work out a more scientific method for assimilating and synthesizing the vast amount of evidence constantly submitted. To some extent the more technical sociological journals are succeeding in this respect but in a less complete manner than for instance in History, Economics, or Psychology. The chief scientific papers continue to appear in *The American Journal of Sociology* (Univ. of Chicago); *The Journal of Applied Sociology* (Univ. of Southern California); *Social Forces* (Univ. of North Carolina); *The Proceedings of the American Sociological Society; The Survey* (N. Y.). Other specialized periodicals dealing with special social problems are *Opportunity: A Journal of Negro Life* (N. Y.); *The Family* (N. Y.); *Hospital Social Service* (N. Y.).

Books.—Among books must be classed a great mass of so-called sociological literature, some of which is good, much of which is worthless or worse. In 1925 sociological books rank next to fiction and religion in the number of annual volumes. Closely allied are books dealing with the subject of religious experience, and especially the evolution controversy (more than seven hundred in all) many of importance to the sociologist. During the year in the entire field *Social Forces* has reviewed or noted more than four hundred and fifty volumes.

Publishers are interested in scientific series, through which the best authors may contribute to the more technical and scientific literature of sociology. No less than eight such sociological series have been planned or begun during the year. Thus, while the year has not produced many outstanding texts it has laid the foundations for a renaissance in social theory and specialized social science.

SOCIOLOGY APPLIED TO HISTORY AND GOVERNMENT

By Malcolm M. Willey and Stuart A. Rice
Professors at Dartmouth College

Point of View.—It is clear that when sociology makes a contribution to history, government and the other social sciences, this contribution is in the form neither of a body of specific subject matter which the latter can take over, nor in the form of a methodology available for their use. It is rather a point of view, applicable to the special problems arising in the older fields. A vast amount of literature has appeared during the past year exemplifying this point of view. Outstanding, because of breadth of scope and detail of treatment, are two volumes issued through the efforts of Harry Elmer Barnes. The first, *The History and Prospects of The Social Sciences*, written by twelve eminent authorities and edited by Professor Barnes, traces the relationships among the various social sciences; the second, *The New History and the Social Studies*, by Professor Barnes himself, covers the same ground in more detail, and includes extensive bibliographical data. In both volumes there is clearly the recognition that a social viewpoint, developed and stressed by the sociologists, is essential in all of the special fields. Relating to history, Professor Barnes phrases it: "In attempting to indicate the nature of sociology and its relation to history . . . it will suffice to state that in the first place, sociology assumes at the outset the premise, which it has well established by inductive historical study, that human life and culture have developed in a group setting. . . . This assumption does not carry with it the doctrine of complete group determinism . . . but sociology does insist that, however much must be allowed for individual initiative, human progress has been more sharply conditioned by its social setting than by any other cause operating upon the life of man." It is this *viewpoint*, which has been growing rapidly and unmistakably, that is the outstanding contribution to the field of history; and it is the recognition of its validity that is already changing the writing of history, as shown in the works of such men as Charles A. Beard, Arthur M. Schlesinger, James T. Shotwell, James Harvey Robinson and others of the same school. Albion W. Small in his recent *Origins of Sociology* (1924) also develops clearly the interrelationship between the two fields of study, and shows the reactions of each upon the other.

Government. — This view extends to the field of government where it leads to a challenge of much of the older political philosophy. For example, the theory of state sovereignty is being questioned by those who utilize the sociological approach. Professor W. Y. Elliott formulated this issue in an article, "Sovereign State or Sovereign Group" (*Am. Pol. Sci. Review*, August, 1925). The influence of sociology is seen in a position rapidly gaining adherents which is stated as follows: "Like the universe itself, the state is ultimately a pluralistic arrangement of group forces, among which government, at its most absolute, can arrange but a temporary and tolerable resolution."

Evidence of this permeation is found in the growth in the last two years of a new publication, *Social Forces*. Although sponsored by the department of sociology of the University of North Carolina, and edited by Professor Howard Odum, head of that department, the scope of this journal, as indicated by the range of material covered, has been greatly enlarged beyond that of the older *American Journal of Sociology*, the official publication of the American Sociological Society. It carries as a regular feature a "Department of Government, Politics and Citizenship." In addition to this and to numerous general articles, of interest to those whose primary fields of research and study are history and government, is the large number of books within these associated fields regularly reviewed in the book section of the publication. This indicates on the one hand that many of the newer books on history and government have become of interest and concern to sociologists; on the other, that these books are being tinged sufficiently with a sociological viewpoint to warrant their inclusion in a sociological journal.

Graduate Work.—The same trend is shown in a similar manner by the character of the theses submitted for advanced degrees in the graduate schools. Not only do many of those within the departments of sociology include an analysis of historical materials, but the obverse is likewise true: theses submitted in departments of history and government increasingly rest upon a sociological orientation. "Dissertations in Sociology" (*Am. Journal of Sociology*, Sept., 1924); "*Doctoral Dissertations in* Political Science" (*Am. Pol. Sci. Review*, Feb., 1925); "List of Doctoral Dissertations in Preparation in American Universities" (Carnegie Institution, Department of Historical Research, Dec., 1924).

Science of Politics. — In government this enlargement of the bases of theory has assumed organized form. "Political Science" has in the past been based primarily upon *assumptions* concerning the nature of man and his institutions. As such it would have been more accurately described as "political philosophy." The newer sociological tendencies are shown by the desire of a number of political scientists to develop a "science of politics." This led to the calling in 1923 of a "national Conference on the Science of Politics," and a second conference at Chicago, September 8-12, 1924. Organized on a round-table basis the sessions were continued at the Christmas meeting of that year of The American Political Science Association, while a third annual conference was held in New York, September 7-11, 1925. Again the round-table sessions were continued December 28-30, 1925, at the meeting of the older organization. The point of view animating the participants in these conferences has been essentially sociological. Their aspiration has been to measure the forces involved in political alignments, political behavior, and political institutions generally. These forces, it is recognized, are essentially social, and attention has therefore been thrown back upon the social groupings out of which the political life of the nation has evolved.

Political Organization.—One of the leaders and chairman of its round-table on political statistics, Professor Holcombe of Harvard, has exemplified the social attitude toward politics in his book, *The Political Parties of Today* (1924). The thesis of the author developed with reference to the entire history of parties in the United States is that social groupings, primarily economic in origin, determine political alignments and political behavior. A similar approach is employed in a number of books and articles appearing in the past year: Merriam and Gosnell, *Non-voting* (1925), is a study of the neglect by half of the eligible voters of the city of Chicago to take part in an election. Stuart A. Rice, a sociologist, in *Farmers and Workers in American Politics* (1924), has shown the necessity for examining socially inherited group-*mores* as a basis for an estimate of the probabilities of farmer-labor coöperation. Seba Eldridge in *Political Action* (1924) adds a further contribution, as does a still later book by Professor Merriam, *New Aspects of Politics* (1925). Two articles in the *American Political Science Review*, August, 1925, "Rainfall and the Populist Party in Nebraska," by John D. Barnhart; and "Sectionalism in Congress (1870-1890)," by Hannah Grace Roach, develop explanations in sociological terms of some of the important political events of the first fifty years. It is doubtful if any of these would have been written except under the impetus of the sociological point of view. A similar motivation is dominating the work of Professors A. B. Hall of the University of Wisconsin, John A. Fairlie of the University of Illinois, Victor J. West of Stanford, Arthur Macmahon, Raymond C. Moley and Joseph McGoldrick of Columbia, Ben A. Arneson of Ohio Wesleyan, Erwin F. Meyer of Colorado College, Harry A. Barth of the University of Oklahoma, Phillips Bradley of Amherst, and numerous other political scientists.

University Schools and Institutes.—The most outstanding illustration of the deliberate attempt to base political theory upon a sociological foundation is afforded by the work of the recently established School of Citizenship and Public Affairs at Syracuse University (1924). Under the leadership of William E. Mosher, its director, and Floyd Allport, the psychologist attached to the staff, a series of experiments in the character, formation, and operation of public opinion are being carried on. The results of this series of experiments, as yet unpublished, will undoubtedly prove of outstanding significance for the future development of a science of politics.

Similar implications may be found in the work of a number of other established organizations. The Institute of Politics at Williamstown, Mass., meeting July 23 to August 22, 1925, had as the topic of one of its round tables, "Agricultural and Population Increase," in charge of Professor E. M. East, of Harvard. The problem involved is one of the most familiar in sociological discussion.

The Social Science Research Council during 1925 granted fifteen research fellowships for the coming year. The integration of the social studies is well illustrated by some of the projects for which grants were awarded. Thus, Dr. Thomas P. Martin, Associate Professor of American History at the University of Texas, has as his problem *A Study of Anglo-American Relations as Influenced by Economic, Political and Social Forces Playing Within and Between the Two Peoples.* On the other hand, an assistant professor of Sociology, Dr. Mildred D. Mudgett of the University of Minnesota, is studying *Legislation Affecting the Pre-School Child in Certain European Countries.*

The National Council for Social Studies met February 21-25, 1925, in Cincinnati. Standards were recommended for the high school teaching of history, government, economics and sociology under a plan of close coordination. That the integrative tendencies represented by these proposals are operating likewise in higher institutions is shown by the organization of a joint research committee of the social science departments of the University of Chicago.

The past year has given added assurance to those who have perceived for a number of years a coming breakdown of hard and fast lines between the various social sciences and the permeation of all of them by the generalized point of view which can best be described as sociological, and which is the culmination of the researches and analyses of two generations of sociologists.

MENTAL TESTS AND MEASUREMENTS

By Rudolph Pintner
Professor at Teachers' College, Columbia University

Present Status of the Testing Movement.—The past few years have seen the gradual acceptance of psychological tests as useful tools in education, business and industry. From the early beginnings of the movement, when tests were in general held up to ridicule, we have passed, through the period of their proclamation by misguided enthusiasts as the solution of all racial and educational ills, to the present time, where tests are beginning to find their rightful place in school and society. Their immediate value as a tool for classification in school, college, office and shop is beginning to be understood by the well-informed. They are not expected any longer to perform miracles. They are recognized as an outcome of the advance of the science of psychology in its attempt to measure the reactions of individuals to the various stimuli that surround them. Looked at from this standpoint, it is very obvious that the several tests so far constructed are woefully few in number and very crude as measurements of precision. We may confidently expect, therefore, much work in the future which will enlarge the field of measurement and at the same time make the measurement itself more exact.

Such results as have been obtained up to the present time by intelligence tests in schools and by the testing in the army during the war have occasioned much discussion during the past year both in scientific and popular journals. The argument would seem to center round the question as to whether our tests are testing native intelligence, pure and simple, uninfluenced by environment; or whether they are mere tests of acquired knowledge. Is there such a thing as intelligence which is inherited? Apart from grossly feebleminded people and geniuses, are not all the differences in intelligence as measured by our tests directly due to differences in environment and opportunities for education?

We have here once again an aspect of the age-old and futile discussion of the importance of environment as against the importance of heredity.

Those who believe in the dominance of the former are inclined to belittle the results of intelligence testing. The superiority of the intelligence ratings of well-to-do as compared with poor children, of city as compared with country children, of white as compared with negro children, is wholly attributed to differences in educational opportunity. Those who believe in the dominance of heredity claim that such superiority is largely, if not wholly, due to inherited native ability. The champions of Nordic superiority have tried to use the results of intelligence testing in support of their claims. The self-appointed guardians of democracy have assailed the tests as undemocratic and odious in the distinctions they are creating among children, and would seem almost to regret the aid they are giving in fitting education to the needs of the individual child. While such general discussions of the final implications of the testing movement are always amusing and at times stimulating, it is fortunate that they have not interfered with the steady growth of test construction and test application.

Types of Intelligence Tests.—Recent work in measurement shows an increase in the different kinds of tests. We may make a rough division of tests into three kinds: (a) Intelligence, (b) Character, (c) Achievement. Under the heading of intelligence we include all the group and individual tests for measuring general capacities of different sorts. Among individual tests the Binet-Simon type of test is still dominant, although the latest so-called "Revision" of this scale, namely, the Herring Revision (1922), departs quite decidedly in method of computing mental age from the original Binet Scale. Further evidence of work with the Binet Scale is found in the appearance of a new revision of the Yerkes Point Scale (1923) and also a new revision of the Kuhlmann Tests (1922). The scope of the Binet Tests has recently been increased by an adaptation of the Stanford Binet Scale for blind subjects (1923).

With reference to individual tests not of the Binet variety we notice an increased interest in performance tests. This is probably due to the expansion of our concept of intelligence. General intelligence may be conceived of as ability to learn or adapt to all sorts of situations. So we may assume at least three kinds of intelligence, namely abstract, concrete and social. The Binet type of test is thought of as testing primarily the abstract type of intelligence. There is therefore need of other types of tests, such as performance tests in order to measure concrete intelligence. No new performance scale has recently appeared, but the tests forming part of the Pintner-Paterson Performance Scale have frequently been used either as units or in new groupings. It would seem that this concrete intelligence as tested by performance tests is positively related to abstract intelligence. Several new performance tests have been constructed and more or less standardized as separate individual tests.

Tests for Young Children.—Perhaps the most striking and original development in this field of individual testing has been the recent interest in the construction of tests for very young children. Up to recent times the only tests for infants below three were contained in Kuhlmann's Revision of the Binet. Recently many workers have turned their attention to tests for infants and we may now say that we are at present in the midst of active work in this field. Already there are numerous tentative tests and norms. Of particular importance in this connection is the work of Woolley at the Merrill-Palmer School, the work of Baldwin and Stecher at Iowa and the work of Gesell at Yale. None of these scales or series of tests lays claim to the same degree of accuracy in mental measurement as does the Binet series for school children. This interest of the psychologist in tests for the very young child is part of the general interest in child welfare and pre-school education. The tests form merely one aspect of the general study of the total behavior of the young child, as it is being now studied in several institutes of child welfare, where we find the psychologist, psychiatrist, physician, dietitian, social worker and educator coöperating in a thorough study of the child from birth to school age.

Group Intelligence Tests.—So far we have been describing individual intelligence tests, i.e., tests given to one subject at a time. When we turn to group intelligence tests, we find that, although they have been used enormously in schools and colleges, very few new tests have been constructed during the past year. The frequent complaint that there are too many tests on the market may have been heeded by the test makers. The most noteworthy new test of the past year is the McCall Multi-Mental Test. It differs from the usual group test in as much as it demands only one type of reaction on the part of the subject throughout the whole test. It lays claim to be as good a measure of intelligence as the more elaborate group tests now in common use.

Levels of Intelligence.—The most important work now being done in intelligence testing is the research work carried on by Professor E. L. Thorndike of the Institute of Educational Research at Teachers' College, Columbia University. A series of intelligence scales are being constructed by means of which various levels of intelligence can be measured and these levels will increase in difficulty by equal steps. Two of these scales are already available and the others, together with a book describing the work, will appear early in 1926.

Character.—The second purpose of tests is to test character. In the field of testing for character qualities, emotional make-up, personality qualities and such other similar aspects of personality not included strictly under intelligence, there continues to be great interest and activity. Special research work in this field is being done by Drs. Hartshorne and May in the Institute of Educational Research of Teachers College, Columbia University. No tests have as yet been published by them.

Terman in his work on gifted children has modified and made use of several character and personality tests. He bases his tests on those originally devised by Voelker, Cady, Raubenheimer, Woodworth and Knight. We therefore have a new set of tests as follows: Overstatement, Reading Preferences, Character Preferences, Social Attitudes, Trustworthiness, and Emotional Instability. These tests have been given to over a thousand gifted and normal children from age seven to fourteen. In addition an extremely interesting test for determining intellectual, social and activity interests has been experimented with.

All this work on the testing of character, temperament and personality is as yet in the experimental stage, and the tests cannot be used by teachers and others for routine work as can our intelligence tests. Nevertheless, there is now no doubt that reliable and objective tests for several character qualities will be available in a very short time, and thus a measurement of qualities, long held to be too intangible for measurement, will be attained.

Achievement.—The third method concerns itself with achievement. Tests of achievement attempt to measure definitely how much a child has accomplished in a certain subject. They are a measure of the influence of the school upon the child. They show how successful the school has been in making those modifications which it set out to make. Recent activity in this field has been great. In addition to tests covering broad fields such as reading or arithmetic, there is a marked tendency to construct tests for much narrower aspects of such subjects. Thus we have Gates' Word Pronunciation Test, the Detroit Word Recognition Test, Gates' Reading of Directions Test, the Whipple High School and College Reading Test, seven tests by Logasa and McCoy for measuring appreciation of Literature, the N. Y. Survey Tests of English Grammar and English Usage. In arithmetic we have the Woody-VanWagenen Tests of the fundamental operations in arithmetic arranged for different grades, also the Buswell Arithmetic tests for diagnosing the particular difficulties of each pupil, and the

Stevenson Problem Analysis Test in Arithmetic. That the field of achievement testing is a very wide one can be seen by the following recently published tests: Michigan Botany Test, Cooprider Biology Test, Dvorak General Science Tests, Illinois Information Test on Foods, Hutchinson Music Test, Gates-Strang Health Knowledge Test, and the Schorling-Sanford Plane Geometry Test. Unquestionably other achievement tests have been published which have not come to the writer's attention.

It is obvious that there is a large demand on the part of teachers for standard tests for all subjects taught in schools. Very little is now taught in schools that cannot be measured with more or less accuracy by standard achievement tests. Such tests lead to a better knowledge of what is being accomplished. They allow a comparison of one school system with another. The extent of some of the testing programs can be envisaged by the nation-wide testing project in Arithmetic Problem Solving, English and Reading now being conducted by the Public School Publishing Company in which over 400,000 pupils in all parts of the United States are enrolled.

Some Uses of Tests.—The routine use of tests by schools, clinics, factories and the like need not be mentioned here. Doubtless millions of individuals have been given standard tests of some sort during the past year. We can only mention in this article some of the outstanding pieces of work.

Terman and his co-workers have reported on their investigation of one thousand gifted children. All of these children had intelligence quotients of 130 or over, and intellectually they fall well within the top one per cent. of the school population. The ratio of boys to girls is greater than that found in the population in general, and the Jewish race contributes about twice as many as the average. These children were given physical and mental tests of all kinds and compared in every case with a control group of average children. The superiority of the gifted group is an all-round superiority showing up on physical, intellectual, volitional and character traits of all kinds. Gifted children are not sickly, eccentric prodigies with abnormally developed talents along specific lines. They are on the contrary regular boys and girls with healthy play interests and an active play life.

The importance of this investigation lies in the fact that it gives us for the first time accurate measures of the difference between normal and gifted children in traits other than the purely intellectual. It is not based upon opinion, but upon objective tests of measurable traits. A great many of the newer character tests are made use of. This book will unquestionably have a profound influence upon the attitude of society toward the gifted child. It shows that there are many such children in the world; it shows how they can be discovered and that they possess an abundance of desirable traits, physical, mental and moral. What is the kind of school for them and what is society going to do about it? How shall these children be educated so that they may contribute their best to the welfare of society? This is the challenge that Terman's important work presents.

College Tests.—The interest of colleges and universities in intelligence tests as a means for appraising the mental caliber of their students is everywhere growing. In many such institutions an intelligence test of all new students is now taken as a matter of course. The work done at Columbia has been described fully by Wood. He describes not only the intelligence test but also the new type of objective content examination. "One of the greatest advantages," he says, "of the intelligence test is that it enables the administration to adjust academic load to individual capacity." Many are saved from failure and discouragement and the superior students are given opportunity to use their superior intelligence. In addition to the use of an intelligence test for all students, there is a growing interest in a broader study of the student and what may be described as college personnel work is rapidly increasing.

Vocational Tests.—In the selection of individuals for various jobs, combinations of intelligence and achievement tests of all kinds are being used. The Bureau of Public Personnel Administration, Institute of Government Research at Washington, in the pages of its journal, *Public Personnel Studies,* has published suggested tests for the following positions: Janitor, Bacteriologist, Library Assistant, Painter, Automobile Driver, Pathologist, Playground Supervisor, Road Inspector, Plumber. These examinations make use of the standard intelligence tests in conjunction with newly devised trade or achievement tests for the various occupations.

Tests of abstract intelligence and knowledge of the job may not be sufficient for the selection of proper individuals. In the work of Vitales with street-car motormen we have an example of a different kind of test, in which the individual is measured as to his ability to learn the specific kinds of reactions which are required for his job.

Summary.—We may summarize by noting that both in the field of test construction and application the past year has been very fruitful. The test makers are fully aware that much yet remains to be done in the perfection of the instruments of measurements in those fields where such instruments now exist. There are many aspects of human personality that have not yet been measured, and research as to the possibility of such measurement is proceeding apace. We note also the widespread use of all the instruments of measurement in school and industry. They are evidently serving a very definite purpose and are helping in the solution of important problems.

Publishers of Tests Mentioned Above.—Bureau of Publications, Teachers College, Columbia Univ., N. Y. C.; Public School Publishing Co., Bloomington, Ill.; World Book Co., Yonkers, N. Y.

DIVISION XXXV
AMERICAN LITERATURE

INTERESTS AND TESTS

By J. Duncan Spaeth
Professor at Princeton University

Field.—The following article is primarily a survey of work by American authors in the field of belles lettres during 1925, but in the case of outstanding writers occasional reference is made to books that have appeared since 1919. It is impossible to draw a strict line of demarcation between "belles lettres" on the one hand, and history, philosophy and science, natural, political, social, on the other. Biography and autobiography have frankly been considered as "literature" along with fiction, poetry, essays, and in other fields books of distinct literary merit have been included when not addressed exclusively to the professional scholar. The survey is necessarily partial but it aims to present a cross section of contemporary American literature including "best sellers" as well as books that are caviare to the general. The brief comments aim to characterize rather than to appraise.

Public Taste.—There seems to be a consensus of opinion among publishers that the standard of public taste in books has undergone a notable change for the better in the last ten years. The *Publishers' Weekly* regularly reports fifteen best selling novels and fifteen best selling non-fiction books. Before the war, a sale of over 20,000 for a non-fiction book was very rare. Within recent years, hundreds of thousands of copies have been sold of such books as Wells' *Outline of History,* Walter Page's *Letters* and Papini's *Life of Christ.* The head of a large publishing firm writes: "Since the war, the American public has clearly been reading for background—outlines of history, outlines of science, biographies, volumes of letters and popularized science. The intellectual ferment and self-questioning attitude reflected in this change of reading habit has also been reflected in the large sales of realistic American novels." Three or four years ago, the interest in "realism" of *Main Street* type as opposed to "romanticism" was at its height. To-day there is a reaction as exemplified by the vogue for Sabatini, E. Barrington and such good mystery stories as *Beau Geste,* by Percy Wren. Biography and autobiography have been making tremendous inroads on fiction, in popular favor, though to be sure the newer biography is itself a kind of fiction—*Wahrheit und Dichtung*—as in Maurois' *Shelley,* J. Lucas-Dubreton's *Pepys,* Barrington's *Nelson* and *Byron* (*Glorious Apollo*), Klabund's *Peter the Czar,* and Werner's *Brigham Young* and *John L. Sullivan.*

A well known publisher says: "Ten years ago the national magazines had not reached the state of wide circulation that they have to-day. The public that wanted Zane Grey and Harold Bell Wright still exists today; but this public can buy its product cheaper in the form of big national monthlies and weeklies. Furthermore, magazines having a larger purchasing power than book-publishing companies, can more or less dictate to the author the style of story demanded. Of course, there are important exceptions, and ephemeral books are occasionally bought in large quantities. The outstanding example is, I believe, the sale of *The Sheik*, which is supposed to have sold over 400,000 copies at $2.00 and the same number at 75 cents, and Mrs. Rinehart's *Red Lamp*, a thrilling mystery story (1925), is said to be near the million mark.

No doubt such book lists as the A. L. A. and the Atlantic Monthly Book Shops have their effect on the public taste.

Literary Periodicals.—A notable development in American journalism is the growing importance of the weekly Book Review Section of some of the big metropolitan dailies. Among the most important weekly literary reviews are the *New York Times Book Review* (very influential on account of its wide circulation; Simeon Strunsky's page is always worth while), *The Saturday Review*, N. Y. (Henry Seidel Canby, William Rose Benét, Amy Loveman, Christopher Morley), growing in importance, unconnected with a daily newspaper, and founded after the purchase of the *N. Y. Evening Post* by the Curtis interests had set Mr. Canby and his associates free to start an independent review. The *Boston Evening Transcript Book Review*, the *N. Y. Herald Tribune's* "Books" section (Stuart P. Sherman), *The Chicago Daily News* (Harry Hansen), *The New York World* (Heywood Broun, Stallings), *The New Republic*. Among monthly reviews *The Atlantic Monthly* (conservative), *The American Mercury* (radical; Menckenized criticism), *The Literary Digest International Book Review* (eclectic), and among the scholarly reviews *The Yale Review, The Dial, The Virginia Quarterly Review* (new, 1925), and *The Reviewer* (University of North Carolina Press) are most noteworthy.

Literary Prizes.—The following prizes in various fields of American literature have been awarded since 1919:

Pulitzer Prizes, Excluding History and Drama

In 1919—Novel: Booth Tarkington, *The Magnificent Ambersons.* Biography: Henry Adams, *Education of Henry Adams* (Houghton, Mifflin, 1918).

In 1920—Biography: Albert J. Beveridge, *Life of John Marshall* (Houghton, Mifflin, 1916-19).

In 1921—Novel: Edith Wharton, *Age of Innocence.* Play: Zona Gale, *Miss Lulu Bett.* Biography: Edward Bok, *Americanization of Edward Bok* (Scribner).

In 1922—Novel: Booth Tarkington, *Alice Adams.* Biography: *Daughter of the Middle Border.* Verse: E. A. Robinson, *Collected Poems* (Macmillan).

In 1923—Novel: Willa Cather, *One of Ours.* Biography: B. Hendrick, *Life and Letters of Walter H. Page.* Verse: *Ballad of the Harp Weaver, A Few Figs from Thistles*, and a *Miscellany*, by Edna Millay.

In 1924—Novel: Margaret Wilson, *The Able McLaughlins.* Biography: Michael Pupin, *From Immigrant to Inventor.* Verse: Robert Frost, *New Hampshire.*

In 1925—Novel: Edna Ferber, *So Big.* Biography: M. A. DeWolfe Howe, *Barrett Wendell and His Letters.* Verse: Edwin Arlington Robinson, *The Man Who Died Twice.*

Helen Haire Levinson Prize

($200.00) for a poem or group of poems by a citizen of the United States.

Awarded in 1919—H. L. Davis, *Primipara.*

In 1920—Wallace Stevens, *Pecksniffiana.*

In 1921—Lew Sarett, *The Box of God.*

In 1922—Robert Frost, *Witch of Coös.*

In 1923—Edwin Arlington Robinson, *Advenel Gray.*

In 1924—Amy Lowell, *Evelyn Ray.*

Nation's Poetry Prize ($100.00)

Awarded in 1921—James Rorty, *Prelude: When We Dead Awaken;* Roy Helton, *May Jones Takes the Air.*

In 1922—Gwendolen Haste, *The Ranch in the Coulee;* Martin Feinstein, *In Memoriam.*

In 1923.—Stephen Vincent Benet, *King David.*

In 1924—Scudder Middleton, *Jezebel.*

In 1925—Eli Siegel, *Hot Afternoons Have Been in Montana.*

The Prize ($100.00), A Token of Appreciation for Good Work by a Young Poet, and Offered Anonymously by a Poet.

Awarded in 1919—Mark Turbyfill, *Poems* (1917-18-19).

In 1920—Maurice Lesemann, *A Man Walks in the Wind.*

In 1921—Hazel Hall, *Repetitions.*

In 1922—Robert J. Roe, *A Sailor's Note-book.*

In 1923—H. Stuart, *Poems.*

In 1924—Marjorie Meeker, *A Dialogue and Lyrics.*

In 1925—George H. Dillon, *Preludes.*

The Pictorial Review, Famous Players-Lasky Corporation and Dodd, Mead & Co. prize ($13,500).

Awarded in 1925—Martha Ostenso, *Wild Geese.*

FICTION

BY J. DUNCAN SPAETH

PROFESSOR AT PRINCETON UNIVERSITY

General.—In volume the output of fiction exceeds all other forms of literature together. There is evidence of a reaching out for newer and freer forms as well as for fuller content in the novel. Edith Wharton and Sherwood Anderson have both written interestingly of their art.

The novel of manners, of ideas, of adventure, of psychology, new and old, of satiric realism, of sophisticated romance, of naïve sentimentalism, the regional novel, the historical novel, the mystery novel where plot is all, and the impressional novel where plot is nothing—each kind is represented, and representatives of each kind will be found in our list.

Novels.—Outstanding novels of the year are: Sinclair Lewis' *Arrowsmith* (Harcourt, Brace), Sherwood Anderson's *Dark Laughter* (Boni & Liveright), Willa Cather's *Professor's House* (Knopf), Anne Parrish's *The Perennial Bachelor* (Harper), Christopher Morley's *Thunder on the Left* (Doubleday, Page), Ellen Glasgow's *Barren Ground* (Doubleday, Page), Joseph Hergesheimer's *Balisand* (Knopf, 1924), James Boyd's *Drums* (Scribner), Edith Wharton's *A Mother's Recompense* (Appleton). In *Arrowsmith,* Sinclair Lewis continues to work with a more mature mind and a surer hand the vein of satiric realism opened in *Main Street* and *Babbitt.* *Main Street* stripped the false glamor from the idyllic picture of the rural community that was one of the heirlooms of the sentimental tradition. *Babbitt* exposed the shabby sentimentality of the commercial booster in the booming cities of the Middle West. In *Arrowsmith* the educational ideals of the college Babbitts are subjected to ironic scrutiny. Much of the scene is laid in the medical school of a Mid-western State University, a composite picture rather than a photograph, but the character of Max Gottlieb, whose religion is the relentless pursuit of truth in his laboratory, stands out in clear relief against the motley company of human, all too human, compromisers that crowd the stage.

The story of Arrowsmith himself is the story of a tragic conflict told with remarkable power. Sinclair Lewis is too anxious to prove his point to write "mere literature." His characters prove what he wishes them to prove. His genius is critical. Like Bernard Shaw, he conceals beneath his ironic exterior a burning passion for reality and a blistering scorn for cant and make-believe. In *Arrowsmith* there is more solid workmanship and more concentration of purpose than in any of his previous books.

Sherwood Anderson's *Dark Laughter* is a much more fundamental challenge of current values, because it delves beneath the very foundations of our conventional social structure. *"Dark Laughter,"* as Henry Seidel Canby says with penetration, "is not white laughter, civilized laughter. Sherwood Anderson is not an adept in civilization. In American literature he is opposite to the metaphysical Emerson, the moral Howells, the crafty Hergesheimer and very different from his nearest of kin, Mark Twain." But it is surely Walt Whitman who is Anderson's nearest of kin. The only American writer who could see, in fact did see, New Orleans as Anderson did, is Whitman. Mr. Canby continues: "His imagination is engaged by the instinctive emotions and in this concentration he is more penetrating and more profound than any contemporary writer in this country. . . . It is the world of dark laughter only, but he carries us so far into its dangerous marches that he will have to be reckoned with as one of the pioneers of the imagination." Anne Parrish's *Perennial Bachelor* is more finished in literary form than *Dark Laughter* or *Arrowsmith.* Its canvas is more restricted and reproduces with charming fidelity moving surfaces of life. The scene is laid in and about Wilmington, Del. (the scene of Henry Seidel Canby's *Our House,* 1919), and its theme is the frustration of the lives of three sisters in their devotion to their brother. It is an American *Old Wives' Tale* with more kindliness and humor and sentiment than Arnold Bennett's masterpiece. It depicts the changing manner of life from 1850-1925 from Mid-Victorianism to Modernism. Miss Parrish's craftsmanship is of a high order; it is a novel of manners rather than of ideas; her forte lies in pathos rather than in tragedy, sentiment rather than passion, delicate irony rather than boisterous humor. Willa Cather's *Professor's House* has not the unity and artistic perfection of her earlier *Lost Lady,* nor the breadth of *O Pioneers* and *My Antonia,* that brought her into the front rank of American novelists. But it is a penetrating and subtle study of the character of the professor and his family. In *Thunder on the Left,* Christopher Morley, well known as essayist and humorist of the *Bowling Green,* enters the rank of the novelists. His novel shows him not only as a master of style but as creator of character and prober into the mystery of life.

Historical Novels.—In *Balisand,* Hergesheimer returns to the historical novel. It deals with the period after the Revolutionary war, and the political fight between the Federalists and the Republicans is vividly portrayed. Mr. Hergesheimer stands near the top of modern English writers of fiction in his command over the resources of language. He is colorist and artist and his portraits glow with the tints of life. Another striking historical novel is James Boyd's *Drums,* a vivid study of the Revolutionary days in the Carolinas, and of the conversion of a young Scottish-American from Loyalist to Patriot. Other historical novels worth mentioning are: *We Must March,* Honoré Willsie Morrow (Stokes), the story of Marcus Whitman and the winning of Oregon; *Samuel Drummond,* Thomas Boyd (Scribner), a story of the soil—a farm in Ohio—the Civil War and the victory of a cause that means the defeat of an individual who fought for it.

Regional Novels.—Among the "regional" novels of the year the following are noteworthy:—*The Kenworthys* (Middle West), by Margaret Wilson (Harper), is not as distinguished as her prize-winning *The Able McLaughlins,* but proves she is not a "one-novel" author. Martha Ostenso, *Wild Geese* (Dodd, Mead) Prize Novel (Northwest). Walter Meilenberg, *Prairie,* a novel of the pioneer Middle West, a symptom of the reaction against *Main Street,* and Spoon River realism; an effort to portray the enduring and significant factors in the cycle of the elementary experience of the race. Elsie Singmaster, *Bred in the Bone* (Houghton, Mifflin) in a series of Pennsylvania Dutch stories. She has again portrayed the Pennsylvania German folk with rare sympathy and insight. Lorna Doone Beers, *Prairie Fires* (Dutton). Du Bose Heyward, *Porgy*, deals with the indolent casual swarming life of the negro quarter in a Southern city. *The Wind* (Harper), an anonymous novel of the Texas plains, well done. Helen Hull, *The Surry Family*, is a study of family fortunes in a Michigan town; quiet in tone but distinguished. *Bronze Collar*, John Frederick (Putnams), Southern California. *Dipper Hill*, Anne Bosworth Greene (Century Co.). A sequel to *The Lone Winter* (1923), the two books giving in journal form the narrative of a winter and summer spent on a high remote farm. Lucy Furman, *The Glass Window* (Atlantic Monthly Press—Little, Brown), a story of the Kentucky mountains.

Notable Novels.—The following novels both by writers of established reputation and by the younger and radical group have attracted wide attention:—Henry Adams, *Democracy* (Holt), published anonymously in 1879. Booth Tarkington, *Women* (Doubleday, Page), not a masterpiece like *Alice Adams*, but a bright and penetrating study of the middle-class suburban current-fiction-reading clubable American woman. Edith Wharton, *A Mother's Recompense* (Appleton). Gertrude Atherton, *Crystal Cup* (Boni and Liveright). Ernest Poole, *The Hunter's Moon* (Macmillan). Arthur Train, *The Needle's Eye* (Scribner). Katherine Newlin Burt, *Quest* (Houghton, Mifflin). Louis Bromfield, *Possession* (Stokes), Galsworthian. Donn Byrne, *Blind Raftery* and *O'Malley of Shanganagh* (Century Co.). Harry Leon Wilson, *Cousin Jane* (Cosmop. Book Corp., N. Y.). James Stevens, *Paul Bunyan* (Knopf), an American myth. Carl van Vechten, *Firecrackers*, sophisticated, intended to be amusing, "mantic" rather than romantic. Scott Fitzgerald, *The Great Gatsby* (Scribner). Francis Hackett, *The Nice Young Couple* (Boni and Liveright). John Dos Passos, *Manhattan Transfer* (Harper), a novel of modern New York in the new style in which the consciousness of the writer becomes a mere instrument for registering impressions. Elinor Wylie (Mrs. Wm. Rose Benét), *Venetian Glass Nephew* (Doran), a very well written, dainty literary fantasy. John Erskine, *Private Life of Helen of Troy* (Bobbs-Merrill), cultivated sophistication, in the tradition of Anatole France. Chamberlain, *The Great Van Suttart Mystery* (Putnam). Floyd Dell, *The Runaway* (Knopf). Anzia Yezierska, *Bread Givers* (Doubleday, Page), a vivid Ghetto story, Zolaesque, autobiographical. Nathan Asch, *The Office* (Harcourt, Brace), original in form, interesting psychology of "office people" and a subtle satire on Wall Street. Theodore Dreiser, *An American Tragedy* (Boni and Liveright), Mr. Dreiser's only novel since 1919. Last but not least (in popularity), another of the books that have certainly not proved "caviare to the general" is Harold Bell Wright's *A Son of His Father* (Appleton). Zane Grey's *The Thundering Herd* and James Oliver Curwood's *The Ancient Highway* belong to the vigorous type of "red blooded" fiction. President Lowell's definition of red blood, "that is to say, blood that has not passed through the brain," would be repudiated indignantly by all readers of Zane Grey and Curwood, and their name is legion.

Twelve Leading Novelists

Production for the last five years.

Cather, Willa (all published by Knopf).
- 1920—*Youth and the Bright Medusa.*
- 1922—*One of Ours.*
- 1923—*A Lost Lady.*
- 1925—*Professor's House.*

Wharton, Edith (all published by Appleton).
- 1920—*Age of Innocence.*
- 1922—*Glimpses of the Moon.*
- 1923—*A Son at the Front.*
- 1924—*Old New York.*

1925—*A Mother's Recompense.*
Hergesheimer, Joseph (all published by Knopf).
1921—*Cytherea.*
1922—*Bright Shawl.*
1924—*Balisand.*
Tarkington, Booth (all published by Doubleday, Page).
1919—*Ramsey Milholland.*
1921—*Alice Adams.*
1922—*Gentle Julia.*
1923—*The Fascinating Stranger.* (Short Stories.)
1924—*Midlander.*
1925—*Women.*
Gale, Zona (all published by Appleton).
1920—*Miss Lulu Bett.*
1923—*Faint Perfume.*
Lewis, Sinclair (all published by Harcourt, Brace).
1920—*Main Street.*
1922—*Babbitt.*
1925—*Arrowsmith.*
Glasgow, Ellen (all published by Doubleday, Page).
1919—*Builders.*
1922—*One Man in His Time.*
1925—*Barren Ground.*
Anderson, Sherwood (all published by Huebsch).
1919—*Winesburg, Ohio.*
1920—*Poor White.*
1921—*Triumph of the Egg.*
1922—*Many Marriages.*
1923—*Horses and Men.*
1924—*A Story Teller's Story.*
1925—*Dark Laughter.*
Dreiser, Theodore (all published by Boni and Liveright).
1919—*Twelve Men.*
1920—*Hey Rub-a-Dub-Dub.* (Essays.)
1922—*Book About Myself.*
1925—*An American Tragedy.*
Poole, Ernest (all published by Macmillan).
1920—*Blind.*
1921—*Beggars' Gold.*
1922—*Millions.*
1923—*Danger.*
1924—*Avalanche.*
1925—*Hunter's Moon.*
Cabell, James Branch (all published by McBride).
1920—*Cords of Vanity.*
Jurgen.
Domnei.
1921—*Figures of Earth.*
1922—*Lineage of Lichfield.*
1923—*High Place.*
1924—*Straws and Prayer-books.*
Dell, Floyd (all published by Knopf).
1920—*Moon-Calf.*
1921—*Briary-bush.*
1923—*Janet March.*
1925—*This Mad Ideal.*
Runaway.

Short Stories.—The flood of short stories defies analysis and record. Much is ephemeral, though no doubt symptomatic of the time. Though few will survive, they may serve the future historian of manners as source-material. The vogue of the small town in fiction of the Lulu Bett genre is exemplified in the following: (some of them earlier than 1925) William Allen White, *In Our Town* (Macmillan); short stories of Iowa and Kansas, Rupert Hughes, *In a Little Town* (Keokuk, Ia.) (Harper); Octave Thanet, *Stories of a Western Town* (Scribner); Dorothy Canfield, *The Bent Twig* (Holt); Grace Flandrau, *Being Respectable* (Harcourt, Brace); Laura E. Richards, *In Blessed Cyrus* (New England) (Appleton); Laura Wolcott, *Grey Dream* (Yale University Press); James Branch Cabell, *Rivet in Grandfather's Neck* (McBride), the South; Irvin Cobb, *Old Judge Priest.*

Each year are published the O. Henry Memorial Award Prize Stories (Doubleday, Page). William O'Brien edits an annual anthology of short stories. *More Aces* is the title of the Putnam collection for 1925. The following are worthy of mention: *Half Told Tales,* Henry van Dyke (Scribner); *Dawgs,* Charles Wright Gray (Holt); an anthology of stories about dogs; *Bigger and Blacker,* Octavius Roy Cohen (Little, Brown & Co.); *Married Life,* Edith O'Shaughnessy (Harcourt, Brace), combines sophistication with insight, well written.

BIOGRAPHY

By J. Duncan Spaeth
Professor at Princeton University

General.—Next to fiction biography and autobiography have been most assiduously cultivated, and there seems no diminution of interest on the part of the reading public in biographical literature. Not only is the year's output of high quality, but it is interesting to note the emergence of certain clearly defined newer ways of writing biography. There is the psychological or spiritual biography of which Brooks' *Ordeal of Mark Twain* and *Pilgrimage of Henry James* are examples; Bradford's "psychographs" and Dr. Collins' books are in the same tradition, as also Sherwood Anderson's autobiography, *A Story-Teller's Story*, a notable book having more to do with the inward significance of fact than with its outward order in the course of events; and furnishing the key to Anderson's literary art. There is the "novelized" type of biography, sometimes satiric in tone and influenced by the English example of Strachey's *Victoria.* Dibble's *John L. Sullivan*, Werner's *Brigham Young* and *P. T. Barnum* are in this tradition.

Public Persons.—Interest in memoirs of the war, except the most important, seems much diminished. The two most dominant personalities in American public life in the last generation, Theodore Roosevelt and Woodrow Wilson, have naturally attracted a number of biographers. The definitive biography of neither has as yet been written, but the following biographies and collections of letters that have appeared since 1919 are noteworthy. William Roscoe Thayer, *Theodore Roosevelt, an Intimate Biography* (Boston, Houghton, Mifflin, 1919). Joseph Bucklin Bishop, *Roosevelt and His Time Shown in His Own Letters* (Scribners, 1920). Hermann Hagedorn, *Roosevelt in the Bad Lands* (Boston, Houghton, Mifflin, 1921). Mrs. Corinne Roosevelt Robinson, *My Brother Theodore Roosevelt* (N. Y., Scribners, 1921). Joseph Bucklin Bishop, *Theodore Roosevelt's Letters to His Children* (Scribner, 1923). *The Letters of Archie Butt* (Doubleday, Page). *Selections from the Correspondence of Theodore Roosevelt and Henry Cabot Lodge, 1884-1918*, 2 vols. (Scribner). Oscar King Davis, *Released for Publication: some inside political history of Theodore Roosevelt and his time, 1898-1918* (Boston, Houghton, Mifflin). J. Hampton Moore, *Roosevelt and the Old Guard* (Phila., Macrae-Smith).

Charles Seymour, *Woodrow Wilson and the World War, A Chronicle of Our Own Time* (Yale Univ. Press, 1921). Joseph Patrick Tumulty, *Woodrow Wilson, as I Knew Him* (Doubleday, Page, 1921). Ray Stannard Baker, *Woodrow Wilson and World Settlement, written from his unpublished and personal material* (N. Y., Doubleday, Page, 1922); a history of the peace conference. William Allen White, *Woodrow Wilson, the Man, His Times, and His Task* (Boston, Houghton, Mifflin, 1924); an interesting, though somewhat subjective, interpretation by an admirer. Robert Edwards Annin, *Woodrow Wilson: A Character Study* (N. Y., Dodd, Mead, 1924); accurate and judicial, but his opinions open to controversy. Josephus Daniels, *The Life of Woodrow Wilson, 1856-1924* (Winston, 1924). David Lawrence, *True Story of Woodrow Wilson* (N. Y., Doran, 1924) by a journalist who as an undergraduate in Princeton knew Wilson. Henry Cabot Lodge, *The Senate and the League of Nations* (N. Y., Scribner); a hostile view of President Wilson's character, in which partisan opposition is colored by a personal antipathy that was mutual. Woodrow Wilson also looms large in *The Life and Letters of Walter Hines Page* (3d vol., Doubleday, Page, 1925); probably the most widely read biography of the year. Other notable biographies of Americans, prominent in business, public and professional life, living or recently deceased, are Don C. Seitz, *Joseph Pulitzer* (Simon and Schuster, 1924). Harvey Cushing, *The Life of Sir William Osler* (N. Y., Oxford Univ. Press). Harris E. Starr, *William Graham Sumner* (Holt). Ida M. Tarbell, *The Life of Elbert H. Gary* (N. Y., Appleton); a record of the business career of Judge Gary rather than a biography of the man. Russell Conwell, *The Romantic Rise of a Great American* (*John Wanamaker*) (N. Y., Harper, 1924). (Herbert Adams Gibbons is writing the official biography of Mr. Wanamaker.) *The Memoirs of William Jennings Bryan* (Winston); begun as autobiography shortly before his death and completed by his wife, Mary Baird Bryan. William Allen White, *The Man Who Is President* (*Calvin Coolidge*) (N. Y., Macmillan). Bishop William Lawrence, *Henry Cabot Lodge* (Houghton, Mifflin); a warmly appreciative biography by a life-long friend and admirer. W. H. Downes, *John S. Sargent, His Life and Work* (Little, Brown & Co.). R. F. Dibble, *John L. Sullivan;* a distinguished example of the new "intimate" anecdotal biography, in which one is always aware of the biographer's personality. A subtle satire on J. L. S. and "the crowd." M. R. Werner, *Brigham Young* (Harcourt, Brace); by the author of *P. T. Barnum* (1924); a breezy and highly entertaining biography of the self-styled "Prince of Humbugs," and incidentally a history of American popular taste during the last century. The Lincoln book of 1925 is: W. E. Barton, *Life of Lincoln* (Indianapolis, Bobbs-Merrill); contains some new material. N. A. Stephenson, *Lincoln* (1922) has permanent value as an interpretation of the mystical background of Lincoln's nature, and as a penetrating study of the development of the literary artist in Lincoln. Paul Revere Frothingham, *Edward Everett* (Houghton, Mifflin); the author of the Gettysburg speech that was forgotten is the subject of a notable biography.

Other notable biographies of the year are:—Theodore Clark Smith, *Life and Letters of James Abram Garfield*, 2nd vol. (New Haven, Yale Univ. Press). V. L. Collins, *President Witherspoon* (Princeton Univ. Press). Samuel H. Wandell and Meade Minnigerode, *Aaron Burr* (Putnam). Claude G. Bowers, *Jefferson and Hamilton* (Boston, Houghton, Mifflin). Kenneth B. Murdock, *Increase Mather* (Cambridge, Harvard Univ. Press). Barrett Wendell, *Cotton Mather, the Puritan Priest* (Cambridge, Harvard Univ. Press). Gamaliel Bradford, *Wives* (Harper); seven wives of great Americans; contains his essay on the æsthetics of biography. In lighter vein is: Don C. Seitz, *Uncommon Americans* (Bobbs-Merrill); Brigham Young, Tecumseh, Whitman, etc.; "Pencil Portraits of men and women who broke the rules and won fame."

Literary Persons.—The most notable literary biography that will rank permanently with memorable biographies is Amy Lowell, *John Keats* (Boston, Houghton, Mifflin, 1924). The author's last work. Its value lies not only in the new material added by Miss Lowell from her own collection of Keats mss. and first editions, but in the comment on the poetry of Keats, by a keen critical intellect warmed by the generous sympathy of a fellow-poet. To Miss Lowell, Keats is not romanticist but realist and imagist, and her appreciation is fresh and thoroughly modern. The book is unique, and to the academic critic puzzling, in the combination of the qualities the author brings to her task—the expert in book collecting, the expert in critical theory, and the expert in poetic technic having united in Miss Lowell to produce a book of romantic hero-worship, a new style. Mary Lawton, *A Life-time With Mark Twain* (Harcourt, Brace & Co.); based on the reminiscences of Katy Leary, a faithful family servant and friend. Van Wyck Brooks, *The Pilgrimage of Henry James* (E. P. Dutton & Co.). M. A. DeWolfe Howe, *Barrett Wendell and His Letters* (Atlantic Monthly Press). Ernest Boyd, *H. L. Mencken* (McBride). Isaac Goldberg, *H. L. Mencken* (Simon & Schuster). *Edgar Allan Poe Letters* (till now unpublished); introduction by Mary Newton Stannard (Phila., Lippincott

Co.). Mary Newton Stannard, *The Dreamer;* a romantic rendering of the life of Poe. Joseph Collins, *The Doctor Looks at Biography* (Doran); has an interesting introductory essay on the writing of biography, contrasting the modern Christian with the classical conception of personality: an approach to literary biography from the therapeutic point of view. Albert Bigelow Paine, *Joan of Arc* (Macmillan); a notable biography in the field of medieval history.

The following list shows that the tide of autobiographies is still running strong: *Mark Twain's Autobiography* (Harper, 1924); disappointing. Edward W. Bok, *Twice Thirty* (Scribner); surpasses in interest the *Americanization of Edward Bok,* in its recollections of great men. *Recollections of Thomas Marshall* (Vice President and Hoosier philosopher), *A Hoosier Salad* (Bobbs-Merrill); delightfully written, abounds in humor and anecdote. Maurice Francis Egan, *Recollections of a Happy Life* (Doran). Brand Whitlock, *Forty Years of It* (Appleton). Major General James G. Harbord, *Leaves from a War Diary* (Dodd, Mead). Samuel Gompers, *Seventy Years of Life and Labor* (Dutton). Herbert Quick, *One Man's Life* (Bobbs-Merrill). George Gordon, *My Education and Religion* (Houghton, Mifflin); a delightful autobiography by a great American preacher of Scottish birth. Edward A. Steiner, *Eternal Hunger, vivid moments in personal experience* (Fleming, Revell). E. P. Mitchell, *Memoirs of an Editor* (Scribner). Joseph Pennell, *The Adventures of an Illustrator* (Little, Brown & Co.). T. A. Daly, *Herself and the Houseful* (Harcourt, Brace & Co., 1924); an amusing account of the life of a journalist-poet with a large family. Rheta Child Dorr, *A Woman of Fifty* (Funk and Wagnalls, 1924); remarkable for its personal sincerity. Corra Harris, *As a Woman Thinks* (Houghton, Mifflin Co.); like her previous volumes *My Book and Heart,* and *The Circuit Rider's Wife,* a sincere record of an inward life that is not isolated but richly human. Janet Scudder, *Modelling My Life* (Harcourt, Brace & Co.). Nora Archibald Smith, *Kate Douglas Wiggin as Her Sister Knew Her* (Houghton, Mifflin Co.). Sherwood Anderson, *A Story-Teller's Story* (Huebsch, 1924); a remarkable literary autobiography, revealing an artist staggering to his feet, and slowly but surely finding himself. Jim Tully, *Beggars of Life* (A. and C. Boni, 1924); a kaleidoscope of tramp life; out-Rousseaus Rousseau. One of the most notable biographies of recent years is Michael Pupin, *From Immigrant to Inventor* (N. Y., Scribner, 1923).

AMERICAN POETRY

By J. Duncan Spaeth

Professor at Princeton University

New Verse.—The year's harvest has not been rich in the field of poetry. Perhaps the most noteworthy contributions are:—Edwin Arlington Robinson, *Dionysus in Doubt* (Macmillan). Conrad Aiken, *Priapus and the Pool and Other Poems* (Boni & Liveright). Amy Lowell, *What's O'Clock* (Houghton, Mifflin). Mr. Robinson's early lyric gift has in *Dionysus* been further attenuated by speculation, except in one or two sonnets, but the whole collection is on a high plane both technically and spiritually. Aiken's *Priapus and the Pool,* first published in 1922, has been out of print and is reissued with additional poems. Conrad Aiken belongs to the poets to whom poetry is both "rhythmic creation of beauty" and "criticism of Life." In Miss Lowell's posthumous volume there is nothing that will add to her fame; her main emotional energy had latterly gone into her *Keats,* but she continues in *What's O'clock* to create images of glassy brilliancy that float gaily or sadly down the stream of her fancy.

A survey of the year's verse shows

that the free verse movement has passed its peak; and there is an evident rapprochement between vers librists with an artistic conscience and the users of traditional forms with an open ear for new cadences in verse. Beyond these, and tending in opposite directions, is a fringe of traditionalists and radicals, the latter in their eagerness to pluck up poetry by its roots frequently salvage only the roots and sometimes only the soil clinging to the roots. A fairly representative list of the rising group of American poets would include E. A. Robinson, Robert Frost, Vachel Lindsay, John Gould Fletcher (now resident in England), Conrad Aiken, C. E. S. Wood (his *Maia* is a notable sonnet series, and his *Poet in the Desert* is in the tradition of Whitman, "cosmic" and "social"), Carl Sandburg, Witter Bynner, Louis Untermeyer, Ezra Pound, Edgar Lee Masters, Maxwell Struthers Burt, William Ellery Leonard, John Neihardt, William Rose, and Stephen Vincent Benét, and among the increasing number of women poets at least these: Sara Teasdale, Edna St. Vincent Millay, H. D. (Hilda Doolittle, Mrs. Richard Aldington), Margaret Widdemer, Leonora Speyer, Lola Ridge, Mary Carolyn Davis, Hilda Conkling, Harriet Monroe. Among important recent studies of the new movement in poetry should be mentioned: Amy Lowell, *Tendencies in American Poetry;* Mary Wilkinson, *New Voices;* Clement Wood, *Poets of America;* Bruce Weirich, *From Whitman to Sandburg in American Poetry*, a critical study. Vachel Lindsay *Collected Poems* (illustrated, Macmillan) were originally published in 1923. Mr. Lindsay's later poems are burdened with a conscious symbolism. Stephen Vincent Benét, *Tiger Joy* (Doran Co.), contains his ballad of *David* which won the *Nation* poetry prize several years ago. Maxwell Struthers Burt, *When I Grew to Middle Age* (Scribner). Hilda Conkling's *Ship's Log* was in Leonard Bacon, *Ph.D.'s*—satiric. Lew Sarrett, *Slow Smoke* (Holt). Margaret Widdemer, *Ballads and Lyrics* (Harcourt, Brace). Harriet Monroe, *The Differences and Other Poems* (Macmillan). George H. Dillen, *Preludes.* Hermann Hagedorn, *Ladders Through the Blue* (Doubleday, Page). H. D., *Heliodora and Other Poems* (Houghton, Mifflin, 1924). William Ellery Leonard, *Two Lives* (Huebsch-Viking Press). John Neihardt, *The Song of the Indian Wars* (Macmillan), carries on his epic which was begun in *The Song of Three Friends.* John Harrington Cox (ed.), *Folk-Songs of the South* (Harvard Univ. Press). Nathalia Crane (aetat 12!), *Lava Lane* (Thomas Seltzer) has excited interest of public and critics. Whether written by her or not, it is a surprising bit of work, but its excellence lies in technic and brilliant fancy rather than in depth of emotion. The verses show marked advance on *The Janitor's Boy* and a remarkable background of reading for a child of twelve. Miss Crane's authorship has been doubted by Edwin Markham and warmly defended by William Rose Benét.

Anthologies.—Extent of the "Poetic Revival" is evidenced rather by demand for good anthologies than by the character of the poetic output. The publishers report a phenomenal sale of E. Burton Stevenson, *Home Book of Modern Verse* (Holt, 1924)—includes British poets. Louis Untermeyer, *Modern American Poetry* (3d ed. rev. and enl., Harcourt, Brace, 1925); in its 65th thousand. Other recent anthologies are:—*The Bookman Anthology of Verse.* Richard LeGallienne, *Anthology of American Verse* (Boni & Liveright); a companion volume to his *Anthology of English Verse.* W. S. Braithwaite, *Anthology of Magazine Verse, 1924, and Year Book of American Poetry.* Alfred Kreymborg, *Anthology of the New Verse.* Harriet Monroe, *New Poetry Anthology.* Robert Haven Schauffler, *The Poetry Cure, A Pocket Medicine Chest of Verse* (Dodd, Mead). *Poets of the Future* (Stratford Co., 1916-24); a college anthology. Ray Towner Thompson (ed.), *The Lyric West* (Los Angeles); mostly California verse. Harold Vinal (ed.), *Voices, An Open Forum for the Poets.*

AMERICAN BELLES LETTRES

BY J. DUNCAN SPAETH
PROFESSOR AT PRINCETON UNIVERSITY

Essays.—In the field of criticism America is least mature as compared with Europe. The influence of Croce is perceptible in much of the newer æsthetic criticism that makes pretense to seriousness. Of the classical school of criticism Mr. Paul Elmer Moore, Mr. Irving Babbitt, Mr. Brownell, are the chief exponents. Mr. Mencken is the most lively of the modernists, and has a large following; and as editor of the *American Mercury* appeals to a wide public; Mencken is the subject of an interesting sketch by Ernest Boyd (McBride) and of a full length Ph.D. biography by Isaac Goldberg (Simon and Schuster).

Among the most readable contributions to American criticism in recent years are the books of Stuart Sherman, especially *Americans* and *The Genius of America* (Scribner, 1923). Mr. Sherman believes in "standards," but understands and likes the younger generation, champions the Puritans, but praises Walt Whitman, defends the Middle West against Mrs. Gerould and New England against the barbarians, and is probably the only American critic who can hold imaginary conversations with both Mr. P. E. More and Mr. H. L. Mencken, and emerge smiling. His later conversational essays revive the tradition of the *Autocrat of the Breakfast Table.* He has latterly given up interpreting grown-up literature to the growing generation in the University of Illinois in order to interpret a growing up literature to the grown-ups, as editor of the N. Y. *Herald Tribune* "Books" section.

In the field of chatty essay on books Mr. A. Edward Newton continues to delight his readers. He has the gift of letting his personality flow through the end of his pen, which will make any man an essayist if he have a personality. Mr. George Santayana, besides being poet and philosopher, is a philosophic essayist, who in spite of the somewhat condescending tone of his *Character and Opinion in the United States*, deserves to rank high for the brilliancy of his intellect and the charm of his style. Ernest Boyd, author of *Civilization in the United States,* though an Irishman by birth is an American by residence, and a good European by culture, and is one of our best informed critics in modern European literary movements. A survey of critical tendencies is given in *Criticism in America, Its Function and Status* (Harcourt, Brace), containing essays by critics of such widely divergent outlook as Irving Babbitt, Van Wyck Brooks, N. C. Brownell, Ernest Boyd, T. S. Eliot, H. L. Mencken, Stuart P. Sherman, J. E. Spingarn, George E. Woodberry.

Criticism.—In what may be broadly described as criticism of contemporary American civilization there are three main tendencies. The "race-dogmatists" interpret civilization in terms of race, and racial heredity. Madison Grant's *The Passing of a Great Race;* Stoddard's *Rising Tide of Color* and *The Revolt Against Civilization;* Albert Edward Wiggam's *New Decalogue of Science* and *The Fruit of the Family Tree* (Bobbs-Merrill) are examples of this tendency. Glenn Frank's editorials in *The Century* constituted a notable criticism of this school.

Ellsworth Huntingdon's books belong to the school that emphasizes the importance of climate and physical environment. The third group emphasize cultural or literary influence and social inheritance and however widely divergent their valuations of literary and cultural periods, whether Hellenists, or Medievalists, or Modernists, whether Sociologists or Humanists, they agree in opposing cultural factors to biologic or economic determinism.

Among the more important contributions in the field of essays, criticism, popularized science, and philosophy are to be noted:—*Essays, Lit-*

erary and Critical Academy Papers, by Paul Elmer More, William Milligan Sloane, William C. Brownell, Brander Matthews, Bliss Perry, Paul Shorey, Henry Van Dyke, and Robert Underwood Johnson. Addresses on Language Problems (Scribner). W. C. Brownell, *The Genius of Style* (Scribner). H. L. Mencken, *Prejudices, Fourth Series* (Knopf). James B. Cabell, *Straws and Prayer-books* (McBride). *Points of View, Letters to a Lady in the Country* (Scribner), and *My Dear Cornelia* (Little, Brown & Co.) by Stuart P. Sherman.

Definitions.—Henry Seidel Canby, *Essays in Contemporary Criticism* (Harcourt, Brace, 1922). Edith Wharton, *The Writing of Fiction* (Scribner). Ernest Boyd, *Studies from Ten Literatures.* V. F. Calverton, *The Newer Spirit* (Boni & Liveright); socialized literary criticism. William Lyon Phelps, *Human Nature and the Gospel* and *As I Like It* (Scribner); from the columns of *Scribner's Magazine.* A. Edward Newton, *The Greatest Book in the World* (Little, Brown & Co.); the author of *The Amenities of Book Collecting* and *A Magnificent Farce,* here continues to write charmingly and wittily about his favorite books, plays, and people. Agnes Repplier, *Under Dispute;* a new collection of essays in her best manner. Carl van Doren, *Other Provinces* (Knopf); the Scholar, the Gypsy, the Barbarian, are charming sketches. George Jean Nathan, *The Autobiography of an Attitude* (Knopf); Mr. Nathan's attitude is intended by himself to be striking. He believes that "to him who thinks, life is a comedy." Like Byron he reduces the romantic to burlesque. Meade Minnigerode, *Lives and Times* (Putnam). C. S. Brooks, *Like Summer's Clouds* (Harcourt, Brace). J. B. Priestly, *The English Comic Characters* (Dodd, Mead). Herman J. Weigand, *The Modern Ibsen* (Holt). Lafcadio Hearn, *Confidential Gleanings* [edited by Albert Mordell] (Dodd, Mead). David Grayson, *Adventures in Understanding* (Doubleday, Page); the author of *Adventures in Contentment* tries out his homely philosophy on New York. Nicholas Murray Butler, *The Faith of a Liberal* (Scribner, 1924). Walter Lippmann, *The Phantom Public* (Harcourt, Brace & Co.). W. C. Abbott, *The New Barbarians* (Little, Brown). George Albert Coe, *What Ails Our Youth* (Scribner). Ben Lindsey, *The Revolt of Modern Youth* (Boni & Liveright).

Literary History.—John Macy, *The Story of the World's Literature* (Boni & Liveright); one of the best of the popular "Survey" books, the fashion for which was set by Wells. Carl and Mark van Doren, *American and British Literature since 1890* (The Century Co.). R. L. Lusk, *The Literature of the Middle Western Frontier* (Columbia Univ. Press); scholarly rather than literary. Harold L. Bruce, *William Blake and His Works* (Harcourt, Brace Co.); a contribution to scholarship.

Culture History.—Ralph G. Turner, *America in Civilization* (Knopf). Sydney and Marjorie Greenbie, *Gold of Ophir or The Lure That Made America* (Doubleday, Page); "a romantic record of the making of America more glamorous than most novels, and more significant than most histories." Ludwig Lewisohn, *Israel* (Boni & Liveright). Lothrop, *Social Classes in Post-War Europe* (Scribner); the author of *The Rising Tide of Color* and *The Revolt Against Civilization* writes here rather as a social philosopher than as a race dogmatist. Konrad Bercovici, *On New Shores* (Century Co.); a study of the influence of new environments on old racial stocks. William McDougall, *Indestructible Union* (Little, Brown & Co.). Hendrik Van Loon, *Tolerance* (Boni & Liveright); a study of intolerance throughout history.

Philosophy. — George Santayana, *Dialogues in Limbo* (Scribner); combines philosophic acumen with literary charm. George T. Patrick, *The World and Its Meaning* (Houghton, Mifflin). Durant Drake, *Mind and Its Place in Nature* (Macmillan). Rollo Brown, *The Creative Spirit* (Harper). Stewart Edward White, *Credo, A Layman's Philosophy* (Harcourt, Brace); this is the philosophy of the man of action working inward from the surface world of deed to the central region of personality. Spirited rather than spiritual. Mr. White blazes new trails to old summits. His philosophy is a compound of mysticism and common sense.

Travel and Description.—The few titles here given represent notable books of the year which are genuinely scientific without being too technical to be included under general literature. Samuel C. Schumucker, *Man's Life on Earth* (Macmillan); an excellent statement of the present status of anthropological science by a Christian evolutionist. Matthew Luckiesh, *Foundations of the Universe.* Louis More, *The Dogma of Evolution* (Princeton Univ. Press); an attack on the implications of evolutionism by a physicist from the point of view of philosophical Dualism. R. S. Lull, *Ways of Life* (Harper); a discussion of evolution.

Travel and Adventure.—Carveth Wells, *Six Years in the Malay Jungle* (Doubleday, Page). William McFee, *Sunlight in New Granada* (Doubleday, Page). Clayton Hamilton, *Wanderings* (Doubleday, Page). William Beebe, *Jungle Days* (Putnam). Leo Crane, *Indians of the Enchanted Desert* (Atlantic Monthly Press). Roald Amundsen and Lincoln Wellsworth, *Our Polar Flight* (Dodd, Mead). Lowell Thomas, *The First World Flight, As Told by the Fliers* (Houghton, Mifflin Co.). F. W. Schmoe, *Our Greatest Mountain* (Putnam). C. F. Lummis, *Mesa, Canyon and Pueblo* (Century Co.). Harry Franck, *Roving Through Southern China* (Century Co.). Ellsworth Huntingden, *West of the Pacific* (Scribner). Richard Halliburton, *The Royal Road to Romance* (Bobbs-Merrill); adventures of a Princeton graduate on a journey to remote corners of the world. Lucretia Perry Osborn, *The Chain of Life* (Scribner). Joseph W. Beach, *Meek Americans* (University of Chicago Press). Katharine Fullerton Gerould, *The Aristocratic West* (Harper).

DIVISION XXXVI

LITERATURE AND LANGUAGE

ENGLISH LANGUAGE AND LITERATURE

By Albert Croll Baugh

Associate Professor of English, University of Pennsylvania

Extent of Research.—The labors of American scholars in the field of the English Language and Literature each year fill many volumes and the issues of many special and technical journals. Merely to list the titles of books and articles, dissertations and monographs would take more pages than the limits of this account permit. Much of the material published is of interest only to the specialist who, because of his familiarity with the subjects discussed, is capable of appreciating its significance. In the present survey an attempt is made to record such progress in the field as is of importance to the enlightened public at large.

The English Language.—On the English language the outstanding book of the year is G. P. Krapp's *The English Language in America*, containing within its two volumes discussions of the mother tongue, words of American origin or peculiar to America, literary dialects, style, American spelling, American dictionaries, and a lengthy treatment of American pronunciation during the last two hundred years. Interest in the English spoken in America is evidenced by the establishment of a monthly magazine called *American Speech*. The first issue, which appeared in October, contains among others an entertaining and instructive article on "Conservatism in American Speech," by George H. McKnight. *Academy Papers*, by members of the American Academy of Arts and Letters contains addresses on subjects connected with language by Paul Elmer More, Brander Matthews, and others. G. W. Small has published his dissertation on *The Comparison of Inequality* (Johns Hopkins Univ.).

Old English Literature (449-1150).—Stanley Rypins has edited *Three Old English Prose Texts in MS. Cotton Vitellius A XV* (the MS. which contains *Beowulf*) for the Early English Text Society. M. D. Chubb has edited the Old English poem of *Christ and Satan* (Yale), and J. H. Pitman has published the text and a verse translation of *The Riddles of Aldhelm* (Yale). G. H. Gerould makes an interesting comparison of "Ælfric's Lives of St. Martin of Tours" (*JEGP*),[1] of which there are two, and offers an explanation of "Abbot Ælfric's Rhythmic Prose" (*MP*).

Middle English Literature (1150-1500).—H. R. Patch's "Characters in Medieval Literature" (*MLN*) is an interesting collection of examples of the kind of thumbnail portrait so popular in the seventeenth century. Miss Hope Traver in *The Four Daughters of God: A Mirror of Changing Doctrine* (*PMLA*) supplements her previous study of the allegorical debate between Mercy, Truth, Peace, and Righteousness. Miss Helen F. Rubel writes about *Chabham's Penitential and Its Influence in the Thirteenth Century* (*PMLA*). The interest in Chabham lies in his classification of minstrels, and Miss Rubel's findings confirm Poole's identification of the author, and place the date of his work in the early part of the thirteenth century instead of a century later. Sister Mary Madeleva has published *Pearl: A Study in Spiritual Dryness*, an essay on a famous fourteenth century poem. Another work by the same poet is the subject of a stimulating paper by R. M. Garrett called "The Lay of Sir Gawain and the Green Knight" (*JEGP*). R. S. Loomis's "Medieval Iconography and the Question of Arthurian Origins" (*MLN*) pleads for the use of archæological evidence in the solution of literary problems. Kemp Malone is led to modify his position with respect to the historical original of King Arthur by the discovery of an "Artorius" (*MP*), a Roman general (Lucius Artorius Castus) in Britain in the second century, some incidents in whose career parallel those in the legend of Arthur. J. J. Parry has edited *The Vita Merlini*, attributed to Geoffrey of Monmouth, and has published two articles on the subject, "Celtic Tradition and the *Vita Merlini*" (*PQ*) and "The Date of the *Vita Merlini*" (MP), the latter containing evidence pointing to 1150.

---

[1] Periodicals are cited under the following abbreviations, the reference being always to the volume for the year covered by this review:—*PMLA, Publications of the Modern Language Association of America*—*MP, Modern Philology*—*MLN, Modern Language Notes*—*MLR, Modern Language Review*—*JEGP, Journal of English and Germanic Philology*—*SP, Studies in Philology*—*PQ, Philological Quarterly*—*RES, Review of English Studies*—*RR, Romanic Review*. Titles appearing as theses or in the publications of universities are followed where possible by the name of the university.

Among Chaucer studies "Chaucer and the Church" (*MLN*) is an important article by E. P. Kuhl representing Chaucer as a liberal but no Lollard and illustrating his position by reference to contemporary events and persons. Karl Young interprets "Chaucer's Renunciation of Love in *Troilus*" (*MLN*) as a revulsion of feeling from the unsound morals of the poem and cites an analogous instance. H. Y. Moffett shows by reference to contemporary manorial documents that Chaucer had reason to assign to "Oswald the Reeve" (*PQ*) certain qualities necessary to a capable overseer, and W. C. Curry finds it easier to determine the knowledge and competency of "Chaucer's Doctor of Physyck" (*ibid.*) than to understand clearly his character. P. F. Baum remarks upon some of the difficulties presented by "The Canon's Yeoman's Tale" (*MLN*) and offers incidentally an explanation of the chemistry of the Canon's two experiments. W. Wells points out "A New Analogue to the *Pardoner's Tale*" (*MLN*) in Jack London's story, *Just Meat*.

Late Middle English.—Studies include a privately printed paper by G. L. Kittredge on *Sir Thomas Malory*, an edition by Miss Laura Sumner of a fifteenth century poem on *The Weddynge of Sir Gawen and Dame Ragnell* (Smith), and Reed Smith's *The Traditional Ballad and its South Carolina Survivals* (South Carolina), which contains among other interesting matters new recordings of eleven old ballads. *Progress of Medieval Studies in the United States of America* is the third such annual survey published by J. F. Willard (Colorado).

Modern English Literature (since 1500).—A similar bibliography of the early modern period is T. S. Graves's "Recent Literature of the English Renaissance" (*SP*). L. R. Merrill's *The Life and Poems of Nicholas Grimald* (Yale) is a useful work on one of the contributors to *Tottel's Miscellany.* Studies of Spenser include H. H. Blanchard's "Imitations from Tasso in the *Faerie Queene*" (*SP*), M. Y. Hughes's "Spenser's Debt to the Greek Romances" (*MP*), which decides against direct indebtedness, and F. F. Covington's "Spenser and Alexander Neckam" (*SP*). R. R. Cawley in "Drayton's Use of Welsh History" (*SP*) shows that in a portion of the *Poly-olbion* Drayton was merely versifying the standard history of Wales in his day. T. K. Whipple has published a monograph on *Martial and the English Epigram from Sir Thomas Wyatt to Ben Jonson* (California). W. E. Mead has edited for the Early English Text Society a late Arthurian romance entitled *The Famous Historie of Chinon of England*, written by Christopher Middleton and published in 1597, to which he appends a shorter piece called *The Assertion of King Arthure.*

Elizabethan Playwrights.—*Elizabethan Playwrights* is a one volume history of the English drama from medieval times to the closing of the theatres in 1642, by Felix E. Schelling, the recognized American authority in the field. One of the most picturesque discoveries of the year is J. Leslie Hotson's uncovering of the circumstances of Christopher Marlowe's death. According to documents which he found in the Public Record Office, Marlowe was killed, May 30, 1593, in a quarrel with one Ingram Frizer over the charges for what they had to eat and drink together at a tavern just outside of London.

R. S. Forsythe discusses Marlowe's poem, "*The Passionate Shepherd* and English Poetry" (*PMLA*), particularly tracing the theme of the invitation to love through a surprising number of instances to our own time. T. W. Baldwin offers some valuable new considerations "On the Chronology of Thomas Kyd's Plays" (*MLN*).

Shakespeare.—Much has been published during the year on Shakespeare. The late Raymond M. Alden's *A Shakespeare Handbook* is largely concerned with source material of Shakespeare's plays. G. C. Taylor's *Shakespeare's Debt to Montaigne* is a small but meaty book. Two papers by Hardin Craig, "Shakespeare's Depiction of Passions" (*PQ*) and "The Ethics of King Lear" (*PQ*) illustrate an important tendency in recent criticism to interpret Shakespeare in the light of Elizabethan thought. E. P. Kuhl in a long paper on "The Authorship of *The Taming of the Shrew*" (*PMLA*) pleads for Shakespeare's authorship throughout the play. H. D. Gray in "Heywood's *Pericles*, revised by Shakespeare" (*PMLA*) sufficiently indicates his thesis by his title. Allison Gaw studies the occurrences of "Actors' Names in Basic Shakespearean Texts, with special Reference to *Romeo and Juliet* and *Much Ado*" (*PMLA*) with unexpected results. S. A. Tannenbaum argues at length on the basis of paleography against the identity of "Shakspere's Unquestioned Autographs and the Addition to *Sir Thomas Moore*" (*SP*) and in another paper, "Reclaiming One of Shakspere's Signatures" (*SP*), maintains the genuineness of the signature in a volume of Montaigne. Shakespeare's successors are discussed in Miss E. C. Dunn's *Ben Jonson's Art: Elizabethan Life and Literature as Reflected Therein* (Smith) and Miss M. C. Struble's "The Indebtedness of Ford's *Perkin Warbeck* to Gainsford" (*Anglia*). E. E. Stoll in "The Old Drama and the New" (*MLR*) defends the old against Mr. Archer's attacks.

Commonwealth and Restoration.—Alwin Thaler in "The Shaksperian Element in Milton" (*PMLA*) points out many parallels in thought and phrasing which continue to appear in Milton's work till the end of his life. Miss M. H. Nicholson finds much similarity in "The Spirit World of Milton and [Henry] More" (*SP*) and Miss M. H. Studley discusses matters of source and practice in "Milton and His Paraphrases of the Psalms" (*PQ*). Commonwealth and Restoration drama are the subject of occasional treatment. Under the title *The Comic Spirit in Restoration Drama* H. T. Perry gathers together studies of Etherege, Wycherley, Congreve, Vanbrugh, and Farquhar. J. L. Hotson shows the continuance of "Bear Gardens and Bear-baiting during the Commonwealth" (*PMLA*) and T. S. Graves makes a plausible case for the sporadic appearance of "Women on the Pre-Restoration Stage" (*SP*), at least on special occasions. Miss A. M. Ellis finds "Horace's Influence on Dryden" (*PQ*) both wide and strong. A. H. Nethercot gives us the next two chapters in his dissertation, one on "The Reputation of the 'Metaphysical Poets' during the Age of Pope" (*PQ*), and the other on "The Reputation of the 'Metaphysical Poets' during the Age of Johnson and the Romantic Revival" (*SP*). A. C. Judson in an interesting note entitled "Who Was Lucasta?" (*MP*) finds no evidence that Lovelace died of a broken heart and offers plausible reasons for thinking Lucasta a largely imaginary person.

Eighteenth Century.—Bernard Mandeville's *The Fable of the Bees* has been handsomely edited by F. B. Kaye with scholarly apparatus. H. C. Hutchins' *Robinson Crusoe and Its Printing, 1719-1731* is a bibliography of value both to the scholar and the collector. Largely bibliographical also is W. E. Schultz's "The Music of the Beggar's Opera in Print" (Music Teachers' National Association, *Proceedings*). W. L. Cross has revised and considerably extended his *Life and Times of Laurence Sterne.* Two of Sterne's contemporaries are the subject of volumes of criticism and interpretation, F. T. Blanchard's *Fielding the Novelist: A Study in Literary Reputation* and H. S. Buck's *A Study in Smollett, Chiefly* Peregrine Pickle. Stanley Rypins writes on "Johnson's Dictionary Reviewed by His Contemporaries" (*PQ*), and the original manuscript of *Boswell's Note Book, 1776-1777*, owned by Mr. R. B. Adam, of Buffalo, has been made available in an attractive and inexpensive edition. *Goldsmith's Animated Nature* is the title of a monograph by J. H. Pitman (Yale) and *Italian Landscape in Eighteenth Century England: A Study Chiefly of the Influence of Claude Lorrain and Salvator Rosa on English Taste, 1700-1800* (Wellesley) is a volume by Miss E. W. Manwaring. J. W. Draper's dissertation, *William Mason: A Study in Eighteenth Century Culture* (N. Y. Univ.) is a sizable volume on a minor but interesting poet. Benjamin Bissell traces *The American Indian in English Literature of the Eighteenth Century* (Yale) and J. M. Longaker, in *The Della Cruscans and William Gifford* (Pennsylvania), finds an interesting subject in a small coterie of little known poets.

Nineteenth Century. — *William Blake in This World* is a stimulating book by Harold Bruce. P. Kaufman's "Defining Romanticism: A Survey and a Program" (*MLN*), Walter Graham's "Some Infamous Tory Reviews" (*SP*), and the same author's "Henry Nelson Coleridge, Expositor of Romantic Criticism" (*PQ*) all concern romanticism or the reaction to it. F. V. Morley in *Dora Wordsworth her Book* portrays Wordsworth's family life and the Wordsworth circle. M. J. Herzberg discusses *William Wordsworth and German Literature* (*PMLA*). J. W. Beach offers "Expostulation and Reply" to certain critics of Wordsworth (*ibid.*), and J. R. Moore points out "Wordsworth's unacknowledged Debt to Macpherson's *Ossian*" (*ibid.*). T. M. Raysor gathers together a few "Unpublished Fragments on Æsthetics by S. T. Coleridge" (*SP*). An outstanding book of the year is Amy Lowell's biography of *John Keats* in two large volumes and containing not a little new material. Miss R. D. Cornelius reprints *Two Early Reviews of Keats's First Volume* (*PMLA*), interesting because they are earlier than the three previously known, and Miss M. H. Shackford presents an analysis and critique of "Hyperion" (*SP*) with a consideration of some influences that met in its production. Walter Graham shows how extensive was *Shelley's Debt to Leigh Hunt and the Examiner* (*PMLA*). A. S. Walker in *Peterloo, Shelley and Reform* (*PMLA*) gives an extended account of the "Peterloo Massacre" at Manchester, Aug. 16, 1819, and its effect upon Shelley. W. E. Peck notes a relation between *Shelley, Mary Shelley and Rinaldo Rinaldini* (*ibid.*), and N. I. White in *"Shelley's Prometheus Unbound, or Every Man His Own Allegorist"* (*ibid.*) attacks the usual assumptions of allegory in the poem. F. L. Mott shows the extent and appreciativeness of "Carlyle's American Public" (*PQ*) and H. M. Lydenberg in "What Did Macaulay Say about America?" (N. Y. Pub. Lib.) gives the text of four letters. W. S. Knickerbocker's *Creative Oxford: Its Influence in Victorian Literature* (Syracuse) is an interpretation of the movements and personalities in Oxford in the nineteenth century. L. N. Broughton and B. F. Stelter have completed their *Concordance to the Poems of Robert Browning*, a laborious and valuable piece of work. Judge John M. Gest has published *The Old Yellow Book, Source of Browning's "The Ring and the Book"* in a new translation with notes and critical chapters on the poem and its source. Louis Wann in "Browning's

Theory of Love" (*The Personalist*) arranges sixty-eight poems of Browning which treat of love, and analyzes his various moods. W. O. Raymond presents "Browning's Conception of Love as Represented in *Paracelsus*" (Michigan Academy). In the field of prose fiction Cornelius Weygandt's *A Century of the English Novel* is one of the outstanding contributions of the year to literary history.

Contemporaries.—In the study of contemporary writers S. P. Chase has solved a mystery in "Mr. John Masefield: A Biographical Note" (*MLN*). He shows that the poet was born June 1, 1878, at Ledbury in Herefordshire, finds records of his parents and the family home as well as the home of the aunt who raised the Masefield children after the death of their father and mother. Ernest Brennecke is the author of a (somewhat misnamed) *Life of Thomas Hardy* and a book entitled *Thomas Hardy's Universe.* E. D. McDonald has compiled a *A Bibliography of the Writings of D. H. Lawrence.* Carl and Mark Van Doren have collaborated on a manual of *American and British Literature since 1890* intended both for schools and the general reader. N. J. O'Connor's *Changing Ireland: Literary Backgrounds of the Irish Free State, 1889-1922,* and Miss E. S. Duckett's *Catullus in English Poetry* (Smith) explain their purposes in their titles.

General.—A few more general titles may conclude this survey of a fruitful field. W. L. Cross's *An Outline of Biography from Plutarch to Strachey* is a charming pamphlet with a convenient list of good biographies; J. C. Knight's *Superlatives* is a discussion of interesting characters in literature in an attempt to interest students and other readers in the books themselves; C. T. Goode's and E. F. Shannon's *An Atlas of English Literature* is a useful book of reference; and Edith Wharton's *The Writing of Fiction* is a discussion of numerous problems in the art of story telling by one who has abundant right to speak on the subject.

GERMANIC LANGUAGES AND LITERATURE

By Friedrich Bruns
Professor at the University of Wisconsin

Before 1925.—Every student of German literature who returned to his task after the interruption of the World War must have been impressed by the new trend apparent in the more recent scholarly investigations. The old philological historical school no longer rules. Such works as Wilhelm Dilthey's *Das Erlebnis und die Dichtung* (1906), with its emphasis on the psychological interpretation paved the way. To Dilthey furthermore history of literature was Geistesgeschichte, i.e., history of the human spirit in its various manifestations. Another step forward is Friedrich Gundolf's *Shakespeare und der deutsche Geist* (1911). This book is a biography of German intellectual and spiritual life from the English Comedians to the Romantic School. No book on German literature of the last decade has aroused more discussion than Gundolf's *Goethe* (first publ. 1916, 12th edition, 1925), not a biography, but "Die Darstellung von Goethe's gesamter Gestalt." H. A. Korff *Geist der Goethezeit* (Vol. I, 1923) is another significant contribution. Fritz Strich, disciple of Heinrich Wölfflin, centers his approach to literature about the problem of style. In his *Deutsche Klassik und Romantik* (2d ed., 1924) he applies to literature the principle of Wölfflin that history of art is a history of style, that the spirit and the significance of an epoch is manifest in its style. Strich was preceded to some extent by the work of Oskar Walzel. Walzel is editor-in-chief of *Handbuch der Literaturwissenschaft*, which work is likely to become by far the best history of general literature, a worthy companion to the *Handbuch der Kunstwissenschaft*, by Fritz Burger.

Current.—In the publications of 1925 the chief interest has continued to center on the modern period. Even the Klopstock bicentenary in 1924 evoked but a faint echo. Emil Ermatinger's interpretation of the world-view of Grimmelshausen is the one work of note dealing with an earlier author. Of the works on Goethe, the Jahrbuch stresses Goethe's friendship with Karl August, since this year is the one-hundred-and-fiftieth anniversary of Goethe's going to Weimar. Goethe's relation to Berlin and Potsdam is the theme of a book by Otto Pniower.

This year is the centenary of Jean Paul's death. Three biographies bear witness to the revived interest in Jean Paul: Walter Harich, Johannes Alt and Friedrich Burschell. Besides these Ernst Hartung has shaped an autobiography out of Jean Paul's letters and E. Behrend is editor of a *Jean Paul-Jahrbuch.* To the numerous biographies of Heinrich von Kleist, Friedrich Braig adds one with a distinctly new note: an interpretation of Kleist from the philosophy of Fichte and Christian mysticism. Of the later Romanticists the new edition of Heine by Ernst Elster with its carefully revised text, new biographical introduction and critical notes will be indispensable to the scholar. Thus far the first four volumes have been published. The new edition of Ermatinger-Baechtold *Kellers Leben, Briefe und Tagebücher* contains a great deal of new material.

The centenary of Conrad Ferdinand Meyer is marked by the publication of a biography by Harry Maync. A far less ambitious but most enjoyable little book is the essay by Robert Faesi: compact and complete and never a mere dry summary. The austere art of Stefan George is ably interpreted by Hermann Drahn.

Of the more general works the most important are a history of the German drama by Robert F. Arnold in collaboration with five other scholars; the revised and enlarged second edition of E. Ermatinger's history of German lyric poetry from Herder to the present, and Albert Soergel's description of the latest phase of German literature, continuing his well known book: *Dichtung und Dichter der Zeit.* E. A. Boucke is revising Hettner's *Literaturgeschichte des 18ten Jahrhunderts.* Publication has begun. Paul Merker and Wolfgang Stammler have begun the publication of their *Reallexikon der deutschen Literaturgeschichte.* The German Biographical Year Book, discontinued in 1914, has resumed publication. The present volume covers the period from 1914-1916. What would have been the crowning achievement of the late Albert Köster's career, the history of German literature during the eighteenth century, must remain a fragment. The chapters published deal with the age of rationalism. The struggle between the poet and the censor is the theme of an extensive work by H. H. Houben.

Translations.—A truly astounding phase of German literary activity is the great number of translations. Aside from individual works we find three new translations of Balzac: Insel (Leipzig), E. Rowohlt, and Globus (Berlin); one each of Zola (Wolff—München), Gobineau (Matthes—Leipzig), and Théophile Gautier (Avalun—München).

The interest in things Russian continues unabated. To the two complete translations of Dostojewski (Piper and Insel) is added a third (L. Ladyschnikow—Berlin). This same firm is publishing a new translation of Tolstoy, while the Propyläen-Verlag is sponsoring a complete Turgeniew. A Viennese publisher (Anton Schroll) announces a translation of the selected works of Lope de Vega. Volume VI is just off the press. A Munich firm (Buchenau und Reichert) has undertaken a translation of the works of R. L. Stevenson. Thus Goethe's concept of a world literature still seems a living ideal.

Fiction.—From the great mass of prose fiction Thomas Mann's *Der Zauberberg* stands out supreme and well deserves the attention it has received. Gerhart Hauptmann's latest novel, *Die Insel der grossen Mutter*, is available in an English translation by Willa and Edwin Muir (Viking Press). Does it deserve this attention? A new tragedy of Hauptmann's *Veland* is just off the press. The last volume of Stefan George bears the title *Tage und Taten* (Bondi—Berlin).

BOOK TITLES

WALZEL, Oskar (editor-in-chief).—*Handbuch der Literaturwissenschaft.* (Akad. Verlagsgesells. Athenaion, Potsdam, 1923.)

ERMATINGER, E.—*Weltdeutung in Grimmelshausens Simplicius Simplicissimus.* (Teubner. Leipzig.)

GOETHE - JAHRBUCH. — (Band II. Goethe-Gesellschaft, Weimar.)

PNIOWER, Otto.—*Goethe in Berlin und Potsdam.* (Mittler. Berlin.)

HARICH, Walter.—*Jean Paul.* (Haessel, Leipzig.)

ALT, Johannes.—*Jean Paul.* (Beck, München.)

BURSCHELL, Friedrich.—*Jean Paul. Die Entwicklung eines Dichters.* (Deutsche Verlagsanstalt, Stuttgart.)

HARTUNG, Ernst (editor).—*Jean Paul. Ein Lebensroman in Briefen.* (Langewiesche-Brand, Ebenhausen.)

BEHREND, E. (editor).—*Jean Paul-Jahrbuch.* (Vol. I, Rosenberg. Berlin.)

BRAIG, Friedrich. — *Heinrich von Kleist.* (Beck, München.)

HEINE, H.—*Sämtliche Werke herausgegeben von Ernst Elster.* (Baende I-IV, 2. Auflg., Bibliogr. Institut, Leipzig.)

ERMATINGER-BAECHTOLD. — *Gottfried Kellers Leben, Briefe und Tagebücher.* 3 vols., Cotta, Stuttgart, 1924, 1925.)

MAYNC, Harry.—*Conrad Ferdinand Meyer und sein Werk.* (Huber, Frauenfeld.)

FAESI, Robert.—*Conrad Ferdinand Meyer.* (Haessel, Leipzig.)

DRAHN, Hermann.—*Das Werk Stefan Georges. Seine Religiosität und sein Ethos.* (Hirt, Leipzig.)

ARNOLD, Robert F.—*Das deutsche Drama.* (Beck, München.)

ERMATINGER, Emil.—*Die deutsche Lyrik seit Herder.* (3 vols., Teubner, Leipzig.)

SOERGEL, Albert.—*Dichtung und Dichter der Zeit. Neue Folge. Im Banne des Expressionismus.* (Voigtländer, Leipzig.)

HETTNER, Hermann. — *Literaturgeschichte des 18ten Jahrhunderts.* (Vieweg & Sohn, Braunschweig.)

MERKER, P., und STAMMLER, W.—*Reallexikon der deutschen Literaturgeschichte.* (Lieferungen 1-4. de Gruyter, Berlin.)

Deutsches Biographisches Jahrbuch.—*Überleitungsband 1914-16.* (Deutsche Verlags-Anstalt, Stuttgart.)

KÖSTER, Albert.—*Die deutsche Literatur der Aufklärungszeit.* (Winter, Heidelberg.)

HOUBEN, H. H.—*Verbotene Literatur von der klassischen Literatur bis zur Gegenwart.* (Vol. I, Rauch, Dessau.)

ROMANCE LANGUAGES

BY GEORGE L. HAMILTON
PROFESSOR AT CORNELL UNIVERSITY

FRENCH

Books.—A few books, and numerous articles, during 1925, have covered nearly the whole range of French literature. Of these only the most significant can be noted here. Most important for linguistic studies, is D. S. Blondheim's *Les Parlers judéo-romans et la Vetus latina. Etude sur les rapports entre les traductions bibliques en langue romane des Juifs au moyen-âge et les anciennes versions:* introduction to elements of all the Romance languages. Two contributions to the most important *genre* of Old-French literature, the epic, are worth noting. Lucy M. Gay, writing on *La Chanson de Roland* and *La Chanson de Willame* (*U. W. St., 20, 21-43*), takes issue with Professor Wilmotte's thesis that the latter of these poems was a plagiarism of the former, and Helen F. Rubel in her article, "Chabham's Penitential and its Influence in the Thirteenth Century" (*P. M. La. A.* 40, 225-239), has done the good service of establishing the date, earlier by a century, than that generally accepted, of a *locus classicus* in regard to the jongleurs as the authors and propagators of *chansons de geste.*

Articles.—Suggestive articles have appeared on the Arthurian romances. Particularly original and enlightening are those of R. S. Loomis. Treating of "Medieval Iconography and the Question of Arthurian Origins" (*M. L. N.*, xl, 65-70), he is insistent on the value of archeological evidence in confirming, supplementing and correcting literary tradition, and he presents a concrete example of its value in studying "The Story of the Modena Archivolt and its Mythological Roots" (*R. R.*, vol. 15, pp. 266-84). J. J. Parry, discussing "The Date of the *Vita Merlini*" (*M. Ph.*, xxii, 413-415), puts it after 1150. The same writer in "Celtic Tradition and the *Vita Merlini*" (*Ph. Q.*, vol. 4, pp. 193-197), finds a common source for the poem, and other versions of its story, in a lost original, a thesis he supports in his edition of the *Vita*, p. 138. (University of Illinois Studies in Language and Literature, vol. 10, No. 3). J. P. W. Crawford, in an article on "El horóscopo del hijo del rey Alcaraz en el *Libro de buen Amor*" (*Revista de filología española*, vol. 12, p. 184), has noted Spanish analogues of an episode in the *Vita*, the prophecy of the threefold death, and A. H. Krappe, in "The Sparrows of Cirencester" (*M. Ph.*, vol. 23, pp. 7-16), reviews the literature of a widely spread folktale, alluded to in the same work. The same writer in a "Note sur un épisode de *l'Historia Britonum* de Nennius" (*Revue celtique*, vol. 41, pp. 181-188), studies the story of "The Tower of Vortigern," which passing into the *Historia* of Geoffrey of Monmouth, and thence into the *Seven Sages*, furnishes an indication of the date of the latter work, as he shows in his "Studies on the *Seven Sages of Rome*" (*Archivum Romanicum*, vol. 8, pp. 386-407). C. Grimm, in "Chrétien de Troyes' Attitude towards Woman" (*R. R.*, vol. 16, pp. 236-243), finds in the varying treatment by the poet of this theme, a key to the chronology of the poet's works, a subject to which is devoted U. T. Holmes "Remarks on the Chronology of Chrétien de Troyes" (*Ibid.*, pp. 43-53).

J. R. Rheinhard, in a long study on "*Amadas et Idoine*" (*R. R.*, vol. 15, pp. 179-265), notes its place in the courtly epic, and its possible Celtic sources, and has published a Picard verse translation of the miracle, "Bread offered to the Child Christ" (*P. M. L. A.*, vol. 40, pp. 93-97), and a useful bibliography of the literature of miracles. To the latter may now be added T. F. Crane's edition of the *Liber de miraculis Sanctae Dei Genetricis Mariae. Published at Vienna, in 1731 by Bernard Pez, O. S. B. With an Introduction and Notes and a Bibliography of the Writings of T. F. Crane* (*Cornell Univ. Studies in Romance Languages*, vol. 1), L. Allen has published an edition of *De l'Hermite et del Jongleur; A Thirteenth Century Conte pieux*, p. 81, Paris, and C. H. Livingston, in his study of "*The Fabliau des deux Anglois et de l'Anel*" (*P. M. L. A.*, vol. 40, pp. 217-224), publishes two unknown analogues, an *exemplum*, and one of the *Cent Nouvelles Nouvelles* of Philippe de Vigneulles, a lost work, discovered by the writer of the article in an unique manuscript. P. G. C. Campbell has published *L'Épitre d'Otnea, Étude sur les sources de Christine de Pisane*, p. 170, Paris, and a supplementary article "Christine de Pisane en Angleterre" (*R. L. C.*, vol. 5, pp. 659-670).

Modern Literature.—Later are Grace Frank in "The Early Work of Charles Fontaine" (*M. Ph.*, vol. 23, pp. 47-60), calls attention to a collection of unpublished poems. H. C. Lancaster, has a note on "Leading French Tragedies just before the *Cid*" (*M. Ph.*, vol. 23, pp. 375-378), and publishes with the collaboration of some of his pupils, (*Chryséide et*

Abbreviations.
J. E. G. Ph.: Journal of English and German Philology; M. L. N.: Modern Language Notes; M. L. R.: Modern Language Review; M. Ph.: Modern Philology; Ph. Q.: Philological Quarterly; P. M. L. A.: Publications of the Modern Language Association; R. H. C.: Revue de Littérature comparée; R. H. L.: Revue de l'Histoire littéraire de la France; R. R.: Romanic Review; U. W. St.: University of Wisconsin Studies in Language and Literature.

Arimand. Tragi-Comédie de Jean Mairet (1625), (*Johns Hopkins Studies in Romance Literatures and Languages*, vol. v). C. Searles discusses the authorship of the anonymous "*Discours à Cliton*" (*Ph. Q.*, vol. 4, pp. 224-230), while G. L. van Roosbroeck has added a new item, illustrative of the same literary quarrel, in "Un document inconnu sur la 'Querelle du Cid,' l'Anatomie du Cid" (*R. H. C.*, vol. 30, pp. 242-252), and has contributed a number of notes of great critical value on "The 'Unpublished' Poems of Mlle. de Scudéry and Mlle. Descartes" (*P. M. L. A.*, vol. 40, pp. 155-168), "The Early Version of the *Comédie des académies*" (*M. L. N.*, vol. 40, pp. 20-25), and "Poems erroneously attributed to Chapelain, Corneille, J. B. Rousseau, La Fontaine, etc." (*Neophilogus*, vol. 11, p. 815).

Eighteenth Century Period.—The following are particularly informing. Thus, van Roosbroeck's "*Persian Letters* before Montesquieu" (*M. L. R.*, vol. 20, *pp.* 432-433), throws new light on an old subject, while F. C. Green, approaching the same work from a different angle, in "Montesquieu the Novelist and Some Imitations of the *Lettres Persanes*" (*Ibid.*, pp. 32-42), shows that it is an attempt to write a novel in letter form, and notes other novels with the same frame-work. The same writer gives an interesting account of a forgotten prolific author of novels, the forerunner of the *roman feuilleton*, in "The Chevalier de Mouhy, an Eighteenth Century French Novelist" (*M. Ph.*, vol. 22, pp. 225-237), while he deals with a more general problem in his "Further Evidence of Realism in the French Novel of the Eighteenth Century" (*M. L. N.*, vol. 40, pp. 257-270). These articles may be considered as complements of a book of distinction by the same author: *La peinture des moeurs de la bonne société dans le roman français de 1715 à 1761*, p. 260, Paris. Van Roosbroeck has published "Notes inédites de Voltaire" (*R. L. C.*, vol. 3, pp. 5-8), and Krappe wishes to find one of "The Sources of Voltaire's *Zaïre*" (*M. L. R.*, vol. 20, pp. 305-309) in the *Ecatommiti* of Giraldi Cinzio. For the first time one finds a full discussion of a fundamental doctrine of Rousseau in G. R. Havens' "La théorie de la bonté chez J. J. Rousseau" (*R. H. L.*, vol. 31, pp. 629-642: 32, pp. 24-37, 212-225), of which one finds, what might be regarded as the criticism, in the same author's "The nature doctrine of Voltaire" (*P. M. L. A.*, vol. 40, pp. 852-862). F. A. Pottle has a note on "The Part played by Horace Walpole and James Boswell in the Quarrel between Rousseau and Hume" (*Ph. Q.*, vol. 4, pp. 351-363). An important work for the history of ideas in France and United States is G. Chinard's *Jefferson et les idéologues* (Johns Hopkins Studies, etc., extra vol. 1).

Nineteenth, and Contemporary Literature. — Many suggestive contributions have been made. J. C. Blankenagel writes on "Goethe, Madame de Staël, and Weltliteratur" (*M. L. N.*, vol. 40, pp. 142-148), while P. Kaufman makes a brave assault on a much discussed literary problem in "Defining Romanticism: A Survey and a Program" (*M. L. N.*, vol. 40, pp. 193-204). A bit of Sainte-Beuve's uncanny information is confirmed in R. Fouré's "Le mariage de Chateaubriand" (*M. L. N.*, vol. 40, pp. 476-480). Much insight into the literary methods of the great French novelist is shown in R. P. Bowen's "Balzac's Interior Descriptions as an Element in Characterization" (*P. M. L. A.*, vol. 40, pp. 289-301), and the sources or analogues of the works of two of the realistic novelists have been noted by A. Coleman, "Some Sources of Flaubert's *Smarh*" (*M. L. N.*, vol. 40, pp. 205-215), Louise B. Dillingham, "A Source of *Salammbô*" (*Ibid.*, 71-76), and Krappe, "*La Chèvre de M. Seguin et l'Ecbasis*" (*R. L. C.*, vol. 3, pp. 365-367).

H. A. Smith in a book, *The Main Currents of Modern French Drama* (N. Y.), vol. 15, p. 320, gives a good deal of information, and judgments which are generally sound upon the French drama since Victor Hugo, while one particular feature of it is studied by Louise Delpit in her *Paris Théâtre contemporain; rôle prépondérant des scènes d'avant-garde* *depuis trente ans*, p. 125 (Smith College Studies in Modern Languages, vol. 6, nos. 1 and 2).

PROVENÇAL

W. P. Shepard has published an excellent critical edition of *Les Poésies de Jausbert de Puycibot* (*Classiques français du Moyen-âge*, vol. 46, pp. 18-94), and has performed the same service for "Two Provençal Tenzoni" (*M. Ph.*, vol. 23, pp. 17-28) of Aiméric de Péguilhan and Albert de Sisteron. O. H. More writes on "Bertran de Born et le Jeune Roi" (*Romania*, vol. 51, pp. 46-75).

ITALIAN

R. D. Austin in his "Dante Notes, VII., Fear no sops" (*M. L. N.*, vol. 40, pp. 339-342), finds the explanation of *suppe* (*Purg.*, vol. 33, p. 38), in Pietro Dante's *Commentary*, where it is glossed by "offa," *i.e.*, "honey-cake," the word used in the episode of the *Aeneis*, the source of the English phrase, "a sop to Cerberus." As illustrative of a fundamental doctrine of the *nuovo stil nuovo*, and of Dante, may be noted G. M. Vogt's "Gleanings for the History of a Sentiment. Generositas virtus, non sanguis" (*J. E. G. Ph.*, vol. 24, pp. 102-124). Ruth S. Phelps, in *The Earlier and Later Poems of Petrarch's Canzoniere* (Univ. of Chicago Press), makes a new and striking contribution to the arrangement of the *Canzoniere*. H. L. Stein, in "The 'Laurea' Note in the Light of the *Secretum*" (*R. R.*, vol. 16, pp. 257-261), attributes the famous note in the poet's copy of Virgil, written on the occasion of Laura's death, to a forger, who used phrases of the *Secretum* in its composition. A. S. Cook has written on the "*Odyssey*, Seventh Book as Known to Petrarch" (*Ph. Q.*, vol. 4, pp. 25-38). A. H. Wilkins, in "The Genealogy of the Genealogical trees of the *Genealogia deorum*" (*M. Ph.*, vol. 23, pp. 61-65), points out that the work of Boccaccio contained the first non-biblical charts in which stems, branches and leaves appear. Krappe would find "The Source of *Novellino*" (vol. 28) (*Neuphilologische Mitteilungen*, vol. 26, pp. 13-18), in an Irish tale. R. Altrocchi publishes the text of "A New Version of the Legend of Saint Alexis" (*M. Ph.*, vol. 22, pp. 337-352). R. S. Phelps, in "The Sources of Lorenzo's *Sacra Rappresentazione*" (*Ibid.*, vol. 23, pp. 29-42), shows the indebtedness of this work to Latin saints' lives, and to a collection by an unidentified French compiler "Nicolas," and Lucile W. Ferguson, in "The Date of the *Raccolta Aragonese*" (*Ibid.*, vol. 23, pp. 43-46), confirms the conjectural date of 1476, assigned to Lorenzo's collection of early Italian poetry. The story, of which a variant is found in Straparola's *Piacevoli notti* (vol. 3, p. 5), has been studied by Ella Bourne, "The Medieval Wanderings of a Greek Myth" (*J. E. G. Ph.*, vol. 24, pp. 184-196).

SPANISH

The publication of the critical apparatus in the second volume of K. Pietsch's *Spanish Grail Fragments, Commentary* (University of Chicago Press), makes it possible to judge of the processes by which the editor has established his rewritten, rather than critical text, published a year earlier. The second volume of R. H. Keniston's *Garcilaso de la Vega* (Hispanic Society), contained a well conceived, and well executed critical text of the author's works, with the critical apparatus, notes and bibliography. W. S. Hendrix has written on *Some Native Comic Types in the Early Spanish Drama* (Ohio State University Studies. Contributions in Languages and Literatures, No. 1). A. R. Nykl in "*Los Primeros Martires del Japon and Triunfo de la Fé en los Reinos del Japon*" (*M. Ph.*, vol. 22, pp. 305-323), dates the first of these works in 1618, and, in tracing its sources, indicates the use made of the second work, in supplying local color. H. C. Heaton, in "The Case of *Parte XXIV* de Lope de Vega, Madrid" (*Ibid.*, pp. 283-303), shows reasons why this publication, known only through Antonio's description, cannot be considered as one of the genuine *Partes*, while G. L. Dale in "*Las Cortes de la Muerte*" (*M. L. N.*, vol. 40, pp. 276-

281), establishes the fact that this *auto*—a hotch-potch of other *autos*—is wrongly attributed to Lope. W. L. Fichter indicates "The Source of Lope de Vega's *El Castigo del discreto*" (*R. R.*, vol. 16, pp. 185-186), in a *novella* of Bandello (*Ibid.*, p. 35), and C. E. Anibal in "'Voces del cielo,' a note on Mira de Amescua" (*Ibid.*, pp. 71-86), calls attention to the literary device of using words, or phrases, casually uttered, as mysterious warnings to the protagonists of the author's dramas. R. H. Williams in his "Notes on the Anonymous Continuation of *Lazarillo de Tormes*" (Ibid., pp. 223-235), presents arguments to show that the episode of the continuation belonged originally to the *Segunda Parte*, from which it had been omitted from fear of the censor. The publication by C. E. Kano of "Cinco sainetes inéditos de Don Rámon de la Cruz con otro á él attribuito" (*Revue hispanique*, vol. 40), and *Ocho sainetes inéditos de Don Rámon de la Cruz*, p. 205 (University of California. Publication in Modern Philology, vol. 13, no. 1), adds much to our knowledge of this prolific and popular dramatist. M. A. Buchanan, in "Further Notes on *Pan y Toros*" (*M. L. N.*, vol. 40, pp. 30-32), establishes an earlier date for this early nineteenth century satire.

G. T. Northup has published *An Introduction to Spanish Literature* (Univ. of Chicago Press), distinguished by its well organized plan, and its succinct summing-up of its subject. S. G. Morley, in "Modern Uses of *Ser* and *Estar*" (*P. M. L. A.*, vol. 40, pp. 450-489), presents a comprehensive treatment, well documented, of the uses of the two verbs; while J. R. Gillet, writing on "The Spanish idiom *fondo en*" (*M. L. N.*, vol. 40, pp. 22-23), gives a new explanation of a curious syntactical construction. A. M. Espinosa in "La sinalefa entre versos en la versificación española" (*R. R.*, vol. 16, pp. 103-121), and in "La compensación entre versos en la versificación" (*Ibid.*, pp. 306-329), has made important contributions to Spanish versification, to which F. O. Reed has added something in a more limited field in his "The Calderonian Octosyllabic" (*U. W. St.*, vol. 20, pp. 73-98).

ANCIENT LITERATURE AND PHILOLOGY

I. LATIN LITERATURE

By John C. Rolfe

Professor at the University of Pennsylvania

Popularizing the Classics.—Both in this country and abroad much attention is devoted at present to popularizing the study of the Classics, and to emphasizing their value in our educational system. This is done in part by making the Latin writers accessible in readable and at the same time accurate translations, with a trustworthy text on the opposite page. The *Loeb Classical Library* (Putnam) has issued about 150 of its handy volumes, of which sixty, or thereabouts, are devoted to Latin writers. One of the recent additions is *Velleius Paterculus*, by F. W. Shipley, and in the same volume the *Res Gestæ Divi Augusti*, the great inscription in which the emperor recorded his personal account of the important events and accomplishments of his long reign. Fragments of another copy of this document have recently been found at Pisidian Antioch. Another new volume contains the *Tristia* and *Epistulæ ex Ponto* of Ovid, by A. L. Wheeler, introduced by an account of Ovid's career which, with Wheeler's *Topics from the Life of Ovid*, in A. J. P.,[*] xlvi, pp.1-28, is a real contribution to a difficult subject. A third volume gives us Frontinus' valuable work on the aqueducts of Rome (*De Aquis*) along with the *Strategemata*. This translation, by the late Professor Charles E. Bennett, was seen through the press by his former pupil, Professor McElwain of Smith College. In France the Association Guillaume Budé, in addition to other classical publications, issues a series of translations on the same general lines as the Loeb, but with more attention to text-criticism and a fuller critical apparatus. In Spain the Fundació Bernat Metge, of Barcelona, announces a series of translations into Catalan, of which several volumes have already appeared.

---

[*] Periodicals are cited as follows: *A.J.P.*, *American Journal of Philology; C.J.*, *The Classical Journal; C.P.*, *Classical Philology; C.Q.*, *Classical Quarterly; P.Q.*, *Philological Quarterly; T.A.P.A.*, *Transactions of the American Philological Association.* A complete bibliography is not attempted.

Relation to Modern Civilization.—Interest in things Roman, and incidentally in the study of Latin, is stimulated besides by books which stress the indebtedness of our modern civilization and culture to those of the Greeks and Romans. This purpose is set forth in the title of the series called *Our Debt to Greece and Rome* (Marshall Jones Co., Boston), in which twenty-three of the projected fifty volumes have now appeared. Recent additions are *Roman Private Life and its Survivals*, by W. B. McDaniel, and *Ancient and Modern Rome*, by the venerable archæologist and senator, Rodolfo Lanciani. The former differs from the ordinary books on Roman private life in calling special attention to the similarity of many customs and beliefs of the modern Italians to those of their Roman forefathers. *Stoicism*, by R. M. Wenley; *Mythology*, by Jane Harrison, and *Architecture*, by A. M. Brooks, are of interest to students of both the classical languages. Books which indirectly teach the same lesson are Grant Showerman's *Eternal Rome* (Yale University Press), Elizabeth Haight's *Horace and his Enjoyment of Life* (E. P. Dutton), and numerous others. That these efforts in behalf of the Classics are justifiable, and even necessary, at the present time is pointed out by S. E. Bassett in his presidential address to the American Philological Association (*C. W.*, xviii, p. 193 ff.); for while the men of most influence to-day are more or less steeped in the Classics and recognize their value in education, when the younger generation assumes complete leadership of thought, there is a danger of a decline in Classical influence. The movement does not represent a different class of laborers in the field, but the authors of such works are also productive in research. In fact, the popular works could not be written by men untrained in investigation. One may perhaps see a favorable sign in the large number of *Classical Articles in Non-Classical Periodicals*, lists of which appear at frequent intervals in *C. W.* In the Loeb Library, Cicero's *De Senectute, De Amicitia and De Divinatione* is the work of a busy lawyer, W. A. Falconer; and T. S. Jerome, former American consul at Capri, has given us a very suggestive book on *Aspects of the Study of Roman History* (Putnam). It may be said without fear of exaggeration that the leading men of our country are convinced of the value of Classical studies, and not a few of them have put themselves on record to that effect. A recently published example is a letter from Woodrow Wilson, at the time a Professor at Bryn Mawr, to the late M. S. Slaughter (*C. J.*, xxi, 3), in which he answers the perennial question, "How can Cæsar be made interesting?" In the same number (p. 11 ff.) C. Pharr, while admitting that Cæsar is the best available prose writer for his place in the curriculum, somewhat needlessly urges the substitution of Ovid.

Report of Classical Investigation.—Teachers of Latin, not content with attempting to inspire the general public with an interest in their work, have been trying also to set their house in order, and render their work more effective, especially by the Classical Investigation undertaken by the American Classical League, under the efficient leadership of Dean West. The results of this survey have been made public in a *General Report* of 302 pages (Princeton University Press), containing valuable statistics, along with recommendations looking to improvements in the school curriculum and in methods of teaching. Another volume gives an account of *The Classics in England, France and Germany*. [The establishment of a summer session of the Classical School of the American Academy in Rome, under the direction of Dr. Showerman, offers to teachers who are unable to spend a longer time in foreign lands the inspiration of study in Italy, an opportunity of which advantage has been taken by a large and increasing number of present and future teachers. The student of to-day has not only the advantage of attractive and handsomely illustrated text-books, but also of lantern-slides (including moving pictures) and all kinds of illustrative material. Two sets of *Phonographic Records of the Roman Pronunciation of Latin* have been produced for his use and are subjected to a somewhat searching criticism in *C. W.*, xviii, pp. 209-213.

Literary Research.—Notwithstanding the time devoted to writings of a popular character, and in spite of a stream of text-books, inspired in part by the recommendations of the Classical Investigation, research has not been neglected. A survey of the recent literature in that line shows increasing variety in the subjects treated, noteworthy activity on the part of women, and somewhat more attention to investigation by teachers in the secondary schools. The text-criticism of the *Letters* of the younger Pliny has been the subject of numerous papers and has given rise to not a little controversy. The merits of the ten-book, the nine-book and the eight-book families of manuscripts, and the trustworthiness of the Aldine editions, have been warmly debated. Two recent articles are *The Eight-book Manuscripts of Pliny's Letters*, by S. E. Stout (in *T. A. P. A.*, lv, pp. 62-72), and *On the 1508 Aldine Pliny*, by Blanche Boyer and J. Dorjahn (in *C. P.*, xx, 50-56). C. U. Clark (*A. J. P.*, xlvi, p. 95) concludes that Aldus was a careful and conscientious scholar, and that the Aldine edition is our most trustworthy witness to the text of the ancient *codex Palatinus*. As usual, a goodly number of articles are devoted to Horace. Lily Taylor (in *A.J.P.*, xlvi, 161-170) revives a view which was held by some scholars in the past, but has been generally ignored in more recent times, that Horace's appointment as a tribune in the army of Brutus gave him permanent equestrian rank. While the most is made of such evidence as is available, it seems doubtful whether an appointment by an assassin of Julius Cæsar would have been recognized by Augustus, or that Horace, in spite of his well-known independence, would have cared to call attention to his former military service with the regicides by assuming the insignia of a Roman knight; not to mention other difficulties. C. Knapp (in *C. W.*, xix, pp. 11-12) presents an analysis of Horace's first satire (i.1), with the view of showing its coherence. T. Frank (in *C. P.*, xx, 26 ff.) has some interesting notes on *Horace's References to Augustus*, involving a new interpretation of Ode xvi in Book iii, and in *A. J. P.*, xlvi, 72-74 he finds a description of a scene in Lucilius in *Serm.* i.5. 85-88. D. L. Drew (in *C. Q.*, xix, 159-164) discusses *Horace, Odes i.12 and the Forum Augustum*, expressing the opinion that Horace made his selection of personal names from a particular section of the portrait gallery of Augustus' "Hall of Fame" (*cf.* Vergil, *Aen.* vi, 703-892), registering a protest against the honor shown to Mars Ultor and the victors at Philippi, perhaps as a "grim and secret jest upon the emperor." In the same periodical (xix, 43 ff.) E. Hancock examines Horace's use of the singular *nos*. The careful study of *Archilochus and the Victims of his Iambics*, by G. L. Hendrickson (*A. J. P.*, xlvi, 101-127), is of interest to students of Horace, as is also the paper of H. Klingelhöfer, *De Livii Capite*, vii.2 (*P. Q.*, iv, 321-344). M. Deutsch continues his interesting studies in Cæsar by *The Murder of Cinna, the Poet* (*C. J.*, xx, 326 ff.) and *Veni, Vidi, Vici* (*P. Q.*, iv, 151 ff.).

Novels and Poetry.—Blanche Brotherton (in *T. A. P. A.*, lv, 128-136) shows that the combination of the hole-in-the-wall motif in the *Miles Gloriosus* of Plautus, combined with an additional trick for bringing about the union of the lovers, is found in oriental tales and was probably used in the Greek original which

Plautus followed. The much discussed question of the origin of the novel of Petronius is the subject of a paper by B. C. Perry (in *C. P.*, xx, 31-49), who finds it in the comic romance, which he believes to have existed in Greece before the days of Petronius. The poetry, declamations, *fabulæ*, and scenes from real life are Roman additions. He classes the work, not as satire, but as a romance influenced to some extent by satire. Petronius was not a moralist, but wrote merely to entertain. An extensive and interesting study of a literary motif to which little or no attention has heretofore been given is B. M. Ogle's *Dame Gossip's Rôle in Epic and Drama* (*T. A. P. A.*, lv, 90-119). He makes a distinction between *Fama*, personified in Vergil's *Æneid*, iv, 173 ff., and representing "a mixture of truth and falsehood tinged with malice," and *fama* in the sense of "a true account, though resting on no definite authority, of actual events." *Fama* in the passage cited brings about a complete change in action and leads to the catastrophe. This is a literary device which Vergil uses nowhere else, and which he did not owe to Homer. He is followed in his personification of *Fama* by Ovid, who did not, however, make Gossip the force which brought about the catastrophe, and unskillfully by the later epic poets. D. L. Drew (in *C. Q.*, xix, 37-42) concludes an article (begun in xvii, pp. 73 ff.) maintaining that the *Copa* preceded the *Eclogues* and giving some further evidence for its Vergilian authorship. In this connection R. B. Steele's *Non-Recurrence of Vocabulary as a Test of Authorship* (*P. Q.*, iv, 267 ff.) is suggestive. W. P. Mustard continues his studies in the Latin writers of the Renaissance by an edition of the *Eclogues* of Antonio Geraldini (Johns Hopkins Press), and A. R. Anderson (in *C. W.*, xviii, 175 ff. and 201 ff.) writes of *Three Modern Latin Epigrammatists:* John Owen, Henrick Harder and Ludwig Halberg.

Miscellaneous.—An interesting article in a different line is E. S. McCartney's *Magic and Weather in Classical Antiquity* (*C. W.*, xviii, 157-159), with a wealth of reference to the sources, and B. Meinecke (*C. W.*, xviii, 157-159) compares the battles of Cannæ and Tannenberg. Works dealing with first-hand material are: *A Latin Document from Egypt*, by H. A. Sanders (in *T. A. P. A.*, lv, 21-54); *The Use of Classical Writers in the Libri Manuales* (text-books in manuscript form and "compendia for mature private study"), by Eva Sanford (in *T. A. P. A.*, lv, 190-248); and E. A. Lowe's presentation of *Some Facts about our Earliest Latin Manuscripts*, forty-seven in number (in *C. Q.*, xx, 197 ff.).

The dissertations presented for the degree of Ph.D. at our various universities are not only a promise of future productiveness, unfortunately not always fulfilled, but an indication of the interests of the professors under whose supervision they are written. C. Knapp (in *C. W.*, xviii, pp. 129-132, 137-142, and 153-154) adds to the lists, published in *C. J.*, of dissertations from 1900-1912 (including some that were not printed) a list of those published between 1912 and 1921, which it is to be hoped may be continued. They are 203 in number and show a great variety of subjects. The references to the lists in *C. J.* are given by Knapp on p. 130.

II. GREEK LITERATURE

By H. Lamar Crosby

Professor at the University of Pennsylvania

One of the most marked tendencies of the day is the endeavor to popularize the life and letters of ancient Greece. This may be accounted for in part by changed conditions in the teaching of Greek both here and abroad; but in part also by a reawakening to the permanent value of the Greek contribution to our civilization. Within the past year the Loeb Classical Library has added to its already extensive collection of

Greek texts with English translation the following volumes: *Aristophanes,* in the famous version of B. B. Rogers; *Homer's Iliad,* Vol. I, by A. T. Murray; *Lucian,* Vol. I, by A. M. Harmon; *Plato,* Vol. III, by H. N. Fowler and W. R. M. Lamb; *Polybius,* Vol. IV, by W. R. Paton; *Strabo,* Vol. III, by H. L. Jones; and *Xenophon, Scripta Minora,* by E. C. Marchant.

Handbooks.—A readable series of handbooks is issuing from the press of the Marshall Jones Company under the joint editorship of G. D. Hadzsits and D. M. Robinson with the general title, *Our Debt to Greece and Rome.* The following volumes, devoted wholly or partly to Greek, have already appeared. In 1922: *Biology and Medicine,* by Henry Osborn Taylor. In 1923: *Aristotle's Poetics,* by Lane Cooper; *Greek Religion,* by W. W. Hyde; *Language and Philology,* by R. G. Kent; *Warfare by Land and Sea,* by E. S. McCartney; and *Mathematics,* by David Eugene Smith. In 1924: *Architecture,* by Alfred M. Brooks; *Mythologies,* by Jane E. Harrison; *Platonism,* by Alfred Edward Taylor; *Sappho,* by D. M. Robinson; *Stoicism,* by Robert Mark Wenley. In 1925: *Aristophanes,* by Louis E. Lord; *Aristotelianism,* by John L. Stocks, and *Homer,* by John A. Scott.

Serving a very similar purpose is E. P. Dutton's series entitled *The Library of Greek Thought,* under the general editorship of Ernest Barker, of which the following volumes are now in print: *Greek Economics,* by M. L. W. Laistner; *Greek Religious Thought,* by F. M. Cornford; *Greek Historical Thought,* by Arnold J. Toynbee; *Greek Literary Criticism,* by J. D. Denniston; *Greek Ethical Thought from Homer to the Stoics,* by Hilda D. Oakeley; and *Greek Social Life,* by F. A. Wright.

The Oxford University Press in 1924 added to its series entitled *The World's Manuals: Ancient Greece,* by Stanley Casson; *Greek Art and Architecture,* by Percy Gardner and Sir Reginald Blomfield; *The Genius of the Greek Drama,* by C. E. Robinson.

R. W. Livingstone, *The Legacy of Greece* (Clarendon Press, 1921), in which were printed notable essays by various distinguished scholars, was followed in 1923 by his *The Pageant of Greece* (Clarendon Press), reissued in abridged form in 1925, in which are given in English dress characteristic passages from Greek literature.

Translations.—Mention should be made also of E. B. Osborn's *The Heritage of Greece and the Legacy of Rome* (Doran, 1924), and *Greek Literature in English Translation,* by George Howe and G. A. Harrer (Harper and Brothers, 1924). E. P. Dutton likewise has recently brought out three volumes of *Broadway Translations* (no date): *The Girdle of Aphrodite,* by F. A. Wright; *Poets of the Greek Anthology,* by F. A. Wright, and *Theocritus, Rion and Moschus,* by J. H. Hallard.

The *Songs of Sappho,* translated into rimed verse by Marion Mills Miller, Greek texts prepared and annotated and literally translated in prose by D. M. Robinson (Maxwelton Co., 1925), is a most ornate edition of that fascinating author. Unfortunately only the wealthy could hope to possess a copy.

While it is hardly to be expected that Aristotle can become truly popular, the Oxford University Press is to be commended for its publication of an English version in charge of W. D. Ross, the eleventh volume of which appeared in 1924: *Rhetorica,* by W. Rhys Roberts; *De Rhetorica ad Alexandrum,* by E. S. Forster; *De Poetica,* by Ingram Bywater. They likewise issued in the same year *The Roman Questions of Plutarch,* translated by H. J. Rose, with introductory essays and a running commentary.

Greek Life and Thoughts.—W. C. Greene's *The Achievement of Greece* (Harvard Univ. Press, 1923) is a most attractive exposition of some of the noteworthy features of Greek civilization, written with sympathetic understanding. Equally to be commended is *Greek Life and Thought,* by La Rue Van Hook (Columbia Univ. Press, 1923). T. R. Glover's *Herodotus* (California Univ. Press, 1924) puts vividly before the reader the unique charm of that prince of storytellers and affords a most valuable picture of the conditions under which he lived and wrote.

We welcome several old friends in

new editions. Jowett's translation of the *Dialogues of Plato*, the plates of which had been lost during the war, received a photographic reproduction in 1924 (Clarendon Press). Gilbert Murray's *Five Stages of Greek Religion* (Columbia Univ. Press, 1925) is a revised and enlarged edition of his well-known *Four Stages of Greek Religion.* The Harvard University Press has given us a new edition (1925) of C. H. Moore's instructive volume, *The Religious Thought of the Greeks from Homer to the Triumph of Christianity.* The fourth edition of *The Greek Commonwealth*, by A. Zimmern, came from the Clarendon Press in 1924. We note also a welcome revision of *Smith's Classical Dictionary of Greek and Roman Biography, Mythology and Geography* (Murray, 1924). The revision is the work of G. E. Marindin. Of special interest to the world of scholars is a revised and enlarged edition of Liddell and Scott's *Greek-English Lexicon.* The work is in the hands of H. S. Jones, who, with the assistance of Roderick McKenzie, has already issued Part I: Α-'Απο βαινω (Oxford Univ. Press, 1925). The sixth edition of the invaluable *Geschichte der griechischen Literatur*, by Wilhelm von Christ, was completed in 1924 by Stählin. That work is in so large a measure enlarged and revised as to deserve to bear the name of the reviser rather than that of the original writer.

Greek Texts.—Among recent editions should be noted Diehl's *Anthologia Græca*, fasc. V. and VI (B. G. Teubner, 1924-5), *Aristotle's Metaphysics*, a revised text with introduction and commentary, by W. D. Ross (Oxford Univ. Press, 1924); Plato's *Euthyphro, Apology and Crito*, with notes, by John Burnet (Oxford Univ. Press, 1924); *Sophoclis Fabulæ*, a critical edition by A. C. Pearson (Oxford Univ. Press, 1924). In the field of papyri, the sixteenth volume of *Oxyrhynchus Papyri*, non-literary texts of the late Byzantine period (Oxford Univ. Press, 1924); C. H. Oldfather's *The Greek Literary Texts from Greco-Roman Egypt* (University of Wisconsin Studies in the Social Sciences and History, 1924), Robert Helbing's *Auswahl aus griechischen Papyri* (Berlin, 1924). The Clarendon Press in 1924 and 1925 published two very imposing volumes from the pen of Walter Scott under the title, *Hermetica.* It consists of a corpus of Greek and Latin writings from Egypt, dating from the Roman Empire, containing religious and philosophical teachings ascribed to Hermes Trismegistus. The work is furnished with an English translation and full commentary and should prove of high interest to students of that period of religious conflict and unrest.

Homeric study still maintains its perennial interest. The third edition of Gilbert Murray's well known *Rise of the Greek Epic* came from the Oxford Univ. Press in 1924. The writer's position has not changed notably from that maintained in his first edition. Adolph Roemer in *Die Homerexegese Aristarchs in ihren Grundzügen* (Ferdinand Schoeningh, 1924) attempts a fresh appraisal of the significance of Aristarchus in connection with the text of Homer. That the well-known mechanical formulæ for the dissection of the poet have not yet been completely discarded is evidenced by a two-volume work entitled *Homers Odyssee* (Buchenau and Reichart, 1925). Vol. I is the work of Dörpfeld and sets forth his views as to the composition of the poems of Homer in Europe prior to the great migrations to Asia Minor. Each poem is conceived as originally covering a period of ten days. Vol. II is a German translation of the Odyssey by Heinrich Rüter, in which he attempts to portray that work as conceived by Dörpfeld. T. W. Allen's *Homer, The Origins and the Transmission* (Clarendon Press, 1924) deserves more extended notice than is here possible. He examines with scientific care several of the moot points of Homeric criticism; but perhaps the most novel contribution of the book is his detailed study of the work of Dictys, on the basis of which he concludes that Homer utilized an old chronicle, perhaps contemporary with the Trojan War. The significance of such a theory can scarcely escape the reader. R. J. Cunliffe's

Lexicon of the Homeric Dialect (Blackie and Son, 1924), while in no wise displacing the familiar works of Ebeling and of Gehring, should prove of real value to people of English speech who essay to read Homer in the original. Grace R. Macurdy's *Troy and Pæonia* (Columbia Univ. Press, 1925) should be of interest to the student of Homer.

Greeks in Spain.—Vol. VI of *Bryn Mawr Notes* (Longmans, 1925) is a very suggestive brochure by Rhys Carpenter on a phase of Greek activity concerning which the evidence is extremely scanty. In *The Greeks in Spain* he combines with inimitable skill the fragmentary testimony of legend and archæology to piece out a picture of the early Greek voyages to Hesperia. An important feature of the little book is the convincing identification of the ancient Hemeroskopeion with the modern Punta de Ifach, an identification based upon a personal acquaintanceship with the particular region in question.

SEMITIC PHILOLOGY AND LITERATURE

By George A. Barton

Professor at the University of Pennsylvania

The Field.—Through Assyriology the field of Semitic philology has been extended beyond its natural and legitimate bounds. The Assyrian language and the Akkadian dialect of ancient Babylonia were Semitic, but another language contained in the cuneiform script, the Sumerian, is studied only by Semitic scholars. Early in 1925 Professor Edward Chiera of the University of Pennsylvania, acting as Annual Professor in the American School of Oriental Research at Bagdad, conducted an excavation at Tar Khelan, on the southeastern border of ancient Assyria, where he discovered the palace of a wealthy man and an archive of about a thousand clay tablets, inscribed in the cuneiform character, and in early Assyrian. These tablets have recently reached the University of Pennsylvania, and promise to open a new vista in the history of the ancient East, as they contain many non-Semitic proper names.

Because the tablets found by the late Professor Winckler at Boghaz Koi, the old Hittite capital in Asia Minor, in 1906 were written in cuneiform, they, too, are studied primarily by Semitic scholars, although their language is Hittite, an Indo-European tongue. Early in 1925 the present writer in the 4th edition of his *Archæology and the Bible* published a translation of a Hittite code of laws, the text of which was found on some of the tablets from Boghaz Koi. Several American scholars had previously discussed phases of the philological relations of Hittite, but with this work America begins to share in the work of interpreting Hittite texts.

Literature.—The fifth volume of the *Annual of the American Schools of Oriental Research* appeared in September, 1925. It contains a number of important articles, but they treat archæological material rather than subjects connected with the languages and literatures of the Semitic peoples.

The year 1925 has been rather a lean one so far as publications in Semitic Philology and Literature are concerned. Professor D. D. Luckenbill's important volume, *The Annals of Sennacherib* (University of Chicago Press), appeared in 1924. The Yale University Press expects to publish in December a volume by Dr. Arch Tremayne, a pupil of Professor Clay, entitled *Records from Erech, Time of Cyrus and Cambyses*. This will constitute one of the volumes of the Yale Oriental Series and will conform in scholarship and execution to the high standard of that series. The texts will consist of business documents and it will add interesting material to our knowledge of Babylonian business and private life.

Professor J. M. P. Smith of the University of Chicago has published an excellent little book, *The Prophets and Their Times*, University of Chicago Press, 1925, which will be a valuable aid in helping many to understand and enjoy the prophetic literature of the Old Testament.

INDO-EUROPEAN PHILOLOGY

By Roland G. Kent
Professor at the University of Pennsylvania

Linguistic Society.—The outstanding event of the year has been the formation and development of a new learned society, the Linguistic Society of America. Through the energy of an organizing committee consisting of L. Bloomfield, G. M. Bolling, and E. H. Sturtevant, a call for a meeting was issued over the signatures of twenty-nine scholars in linguistic subjects. The meeting took place on December 28, 1924, at the American Museum of Natural History, in New York City, and was attended by over seventy-five persons. The name of the society was selected, a constitution adopted, officers elected, and four scientific addresses were delivered. The officers for 1925 are as follows: President, Hermann Collitz (Johns Hopkins Univ.); Vice-President, C. D. Buck (Univ. of Chicago); Secretary and Treasurer, R. G. Kent (Univ. of Pennsylvania); Executive Committee, the preceding, and Franz Boas (Columbia Univ.), O. F. Emerson (Western Reserve Univ.), E. H. Sturtevant (Yale Univ.); Committee on Publications, G. M. Bolling (Ohio State Univ.), A. M. Espinosa (Stanford Univ.), Edward Sapir (Ottawa; now Univ. of Chicago).

The purpose of the Society is, in the words of its constitution, "the advancement of the scientific study of language." Before its formation, linguistic scholars were divided among various organizations, such as the American Oriental Society, the American Philological Association, the Modern Language Association, the American Anthropological Association, and others of a more special character; there was no organization in which they might all meet, no matter what the languages of their special interests might be, and there was no special organ for the publication of their research. The new society, accordingly, plans to remedy this by bringing together at its annual meetings the scholars in linguistics and by providing a series of publications devoted to their studies.

Thus the work of the society during 1925 has been of a twofold nature: the consolidation of the membership, which is now considerably above 300, and the establishment of media of publication, a journal and a series of monographs. The journal *Language*, appearing quarterly, is already a fixture, for the third issue appeared in September and the fourth in December, despite the difficulties of getting under way at the start. The series of monographs will appear at irregular intervals, according to the material offered and the financial strength of the society; the first monograph was distributed toward the end of November. The Linguistic Society has received much favorable notice in the journals of other organizations, notably one in the *Bulletin de l'Association Guillaume Budé* (Paris), No. 9 (Oct., 1925), pp. 49-54.

Problems.—The scholarly output of the year is scattered over the entire field, in the usual manner, and the most important articles are listed below, in the bibliography. The chief single subject which has attracted general attention is the nature of the accent in Latin and the manner of reading Latin verse; for the verse stress, whatever its character, does not systematically accord with the accent in the individual words. To explain this disagreement, certain scholars regard our conventional method of reading Latin verse, with a disregard of the word accents, as wrong; and believe that the prose stresses should be kept, while the quantitative differences of the syllables establish the rhythm. Others think that the word accent of the educated Roman was an accent of pitch or higher musical note, and the metrical accent was one of energy, so that there was no conflict between the two.

INTERNATIONAL AUXILIARY LANGUAGE

BY ROLAND G. KENT

PROFESSOR AT THE UNIVERSITY OF PENNSYLVANIA

General Approach.—The need of a eady means of communication among ll men has been more than ever ealized since the World War multilied and intensified international retions. The demand is no longer for universal language which is to relace existing languages, but for an uxiliary language, which shall be the rst language learned after the other-tongue. The chief languages hampioned for this use have been nglish, French, Latin, and artificial nguages, of which the chief are speranto, Ido, and Flexionless Latin.

The most significant development this field within recent months as the formation, in 1924, of the nternational Auxiliary Language ssociation in the United States, c.," though the actual formation as due chiefly to the interest and e energy of Mrs. Dave H. Morris, New York City. Of this organition, known as the I A L A, the esident is E. B. Babcock, Dean of e Graduate School and Head of the partment of Romance Languages d Literatures in New York Unirsity; the vice-president is J. J. rty, Vice-President of the American legraph and Telephone Company. s purpose, as stated in its charter, to promote study of the questions nected with the I A L, as the inrnational auxiliary language is lled; to work for governmental cognition of the problem, and for ation of an international commisn of experts authorized to select I A L; to further in every way recommendations of this commisn.

The Association starts with the premise that the I A L must be the best possible language for the purpose, and that therefore it is quite certainly a language not yet in existence; that a large amount of research and experimentation must be carried on, before the perfect I A L can be found. It plans a work of research, experimentation, and propaganda, on a very elaborate scale, with a budget of $300,000 for the first five years, during which a fund will be raised whose income will care for the later expenses; the extended activities and the dissemination of the results calls for a further expenditure of $1,500,000. It now has an office, a full-time office secretary, a part-time general secretary (Dr. H. N. Shenton, of the department of sociology in Columbia University), and two part-time research assistants. It raised the funds necessary for carrying on the Thorndike experiment in the controlled teaching of Esperanto and Ido, and entrusted the administration of the funds to Teachers' College (Columbia University). The first tests were made in the autumn of 1925, at Vassar College, with two groups of fifteen students each, studying Esperanto; and at Mt. Holyoke College, with a class in Ido. The I A L A has distributed much mimeographed and printed material (Bulletin No. 1, May, 1925), and maintains a sales department for literature on the subject. In the summer, its representatives held many conferences with representatives of the various artificial languages, at Geneva and elsewhere, for the purpose of securing coöperation in the work of investigation and research.

Various attempts have been made to formulate an international language, including Volapuk, which is an Esperanto no longer current.

1. **Esperanto.** — The headquarters for information is the Esperanto Association of North America (Miss E. J. Meriam, Secretary), Pierce Building, Copley Square, Boston, Mass. Official journal in America, *Amerika Esperantisto*, published monthly at the same address.

About seventy-five periodicals in Esperanto are published in different countries. Esperanto is regularly used for radio broadcasting, at certain hours and certain days, at eight stations in Germany, two each in Paris and Melbourne (Australia), one each in Vienna, Copenhagen, Rome, Moscow, Barcelona, Geneva, Victoria (B. C.), though twelve of the nineteen are merely for Esperanto lessons. The International Amateur Radio Conference at Paris, April 14-18, by a heavy majority recommended Esperanto for international radio communication, and adopted it as an auxiliary language of the conference in addition to English and French. In May, two other International Conferences for the Use of Esperanto were held in Paris, one for its use in the Pure and Applied Sciences (under the Patronage of the French Association for the Advancement of Science), the other for its use in Commerce and Industry (convened by the Paris Chamber of Commerce). Each was attended by representatives from about thirty countries. The annual International Congress of Esperantists met in Geneva, on August 2 and the following days, with a large attendance.

Practically every country of Europe saw its own Esperanto congress in 1925. In this country, the Eighteenth Annual Esperantist Congress was held in Cleveland, in the summer; that of 1926 will be in Philadelphia. Courses in Esperanto are reported at the following institutions (though not given credit for college degrees): Vassar College, Univ. of Minnesota (Extension Div.), Stanford Univ., Mass. State Dept. of Education (Univ. Extension Div.; certificate granted), Case School of Applied
Science (Cleveland), Antioch Coll
(Yellow Springs, O.), Montezu
Mountain School (Los Gatos, Ca
required for two years; entra
credit given by Stanford Univ
There are local Esperanto societ
in many cities, which, among ot
activities, conduct classes in the su
ject. There has been a limited u
of Esperanto in broadcasting in t
country. Many books are publish

Among articles published this ye
on Esperanto, in non-Esperant
journals, are the following:

BUTMAN, M.—"The Internatio
Key" (*Zion's Herald*, April 2
reprinted in *Journal of Educati*
May 31).

SAYERS, J. D.—"Esperanto the N
World Language" (*Current H*
tory, September).

2. **Ido.**—A center for informati
on Ido in this country is Mr. A.
Angman, 1018 Louisa St., Elizabe
N. J., general secretary of The I
ternational Language (Ido) Socie
of America. This society was est
lished in June of the present ye
The Fourth International Congress
Idists was held in the city of Luxe
bourg, August 9-12, with delega
present from many countries.
September, an international conf
ence of Idists was held at Tur
Italy, with representatives from se
eral countries, and in the same mon
a conference of Ido authorities w
held in Geneva. The present offic
organ of Ido is *Mondo*, issued mont
ly in Stockholm.

In January, 1926, was publish
at Stockholm, Sweden, an Intern
ciona Radio-Lexiko, or "Internation
Radio Lexicon," by K. Feder and
Nordin, in Ido, German, Englis
French, Spanish, and Italian, with
separate alphabetical index in Sw
dish; this is said to be the first i
ternational standardization of rad
terminology for professionals a
amateurs. In America, *La Presse*,
French daily journal of Montreal, b
gan in 1924 the use of Ido in i
broadcasting, in addition to Engli
and French. A course in Ido (wit
out credit toward the college d
gree) is being conducted at M
Holyoke College, under the Thorndi

experiment of the I A L A; courses are planned at schools in Lakewood, N. J., and in Lakeville, Conn. E. F. McPike of Chicago has been lecturing on Ido, both with the use of the stereopticon and by radio. He has founded an Ido Club in his own city.

3. **Arulo.**—Center for information in this language is Dr. Max Talmey, 266 W. 113th St., New York City. This is claimed to be an improvement on Ido, better adapted for exact uses, scientific and literary, because it is being carefully worked out by competent linguists and logicians. An English hand-book of Arulo is due to appear in December, 1925, under the title, *Arulo, Text Book of the Universal Language, with Exercises and Specimen of a Dictionary.*

4. **Nov-Esperanto.**—The center for nformation in this country is Mr. E. P. Harlow, World Language Bureau, 1320 Ninth St., Washington, D. C. This language is a project of R. de Saussure, essentially Esperanto without the diacritical marks, and with a few other minor changes. Its author first proposed Esperantida, which occupied a middle ground between Esperanto and Ido, but has given that up in favor of a very slightly modified Esperanto, since he was unable to reconcile Esperantists and Idists by his first proposal. There has been no general congress of its advocates.

5. **Occidental.**—This is a project of Dr. de Wahl. There is a journal of he same name. The grammar is xtremely simple, and the vocabulary is chosen for its internationality.

6. **Latino sine Flexione.**—This creation of Prof. Peano of Turin, Italy, is essentially a Latin with endings emoved. The society for its propaation calls itself Academia pro Inerlingua, of which Prof. Peano is President; its journal, bearing the ame name, appears at Turin about ix times a year. Its work has been one by correspondence, publication, nd special conferences. A North merican branch of the Academia has een established, with V. L. Lowe Bureau of Standards, Washington, . C.) as secretary-treasurer, who ill give information on this lanuage. Radio Pamphlet No. 1 of the War Department has been translated into Latino sine Flexione, with the title *Principios Elementario de Radiotelegraphia et Telephonia.* A two-volume dictionary of English and "Interlingua," as its supporters prefer to call it, is being prepared.

7. **Latin.**—A form of Latin approximating that used in medieval times has been advocated by the American Classical League and by others, but there were no developments in 1925. Information may be secured from R. G. Kent, Univ. of Pennsylvania, Philadelphia.

8. **English.**—Present English is recognized as a prominent competitor for the position of I A L, because of its extremely wide use in commerce, even outside the countries where it is the mother-tongue. A simplified English is advocated as the I A L, by J. W. Hamilton of St. Paul, Minn., founder and executive secretary of the International Magna Charta Day Association; it is termed by him Cosmo-English, but the form which the simplification is to take has not even been agreed upon by its adherents.

9. **French.**—There seems to be no specific propaganda in favor of French, although it is the only modern language besides English which need be seriously considered in this connection. Its claims, together with those of English, are presented favorably by G. de Reynold in the *Revue de Genève* for May and June, 1925, along with a plea for further consideration of the qualifications of Latin, and a condemnation of the artificial languages.

Difficulties.—The weakness of the I A L movement is that there are too many competitors; and the partisans of the different artificial languages are not infrequently quite hostile to one another's projects. Possibly the I A L A, which is not championing any particular language, will improve the situation. But it is an undeniable fact that no artificial language is spoken by a hundredth of the number who speak English or French; and quite possibly commercial use will make English the real I A L, since it is already the international language of the sea, and is the secondary language in many countries. On the other hand, Sapir, of the University of Chicago, in *The Romanic Review* (vol. 45, pp. 244-56), argues in favor of an artificial language far simpler than any yet proposed; and memorandum has gained the appro of such eminent associates as Bloomfield, F. Boas, J. L. Gerig, a G. P. Krapp.

MODERN LANGUAGES

BY REINHOLD EUGENE SALESKI

PROFESSOR AT THE UNIVERSITY OF DELAWARE

Basis of the Study.—The importance of linguistic study to the world in general does not lie in discovering or preserving facts or systems of facts that might as well be lost, but rather in patiently gathering, arranging, and comparing the material that will some day show how far all of us are bound to a particular style of thought and appreciation by the habit of the particular language we speak. A slow, perhaps subconscious realization of this fact, has led to the gradual recognition of two considerations: that the philosopher and linguist must work together, even be united, as far as may well be, in the same person; and that no language can be so primitive or decadent as not to furnish a valuable insight into the question of the power of linguistic symbolism over human thinking.

Wundt was the first to emphasize the first idea, and it is much rarer now that we hear the professional philosopher and linguist expressing antagonism towards each other; or, if they do feel it, they are like Paul and Vendryes, philosophizing, psychologizing, while denying the rights of other philosophers or psychologists in their midst. Drawn into this wider view of their science, willy-nilly, is every linguist today; Jespersen and Vossler avowedly so. This is especially noticeable in the school of Brugmann and Streitberg, the *Junggrammatiker:* in the former's recent contribution to syntax; in the latter's general encouragement of all broader treatments of the subject, as is evident from the articles in the publication in his honor. On the other hand, the youngest generation of linguists, instead of being irritated at the endless labor of gathering minute details of grammar, real that this is the necessary foundati for any deeper understanding of la guage, and begin to believe that who has not mastered the strict sci tific method of this minute labor sure to go astray in his broader co clusions.

Living and Dead Languages. Recognition of the value of the stu of any language is part of the ce tury-old doctrine of modern philolo but only in the last generation h the study of modern languages beg to play an important rôle. The n tive language, of course, and its a joining languages students and sch ars have always studied for th own sake—so Grimm; but the rea zation of the value of living la guages, in spite of the earlier scho of W. von Humboldt and Steinth is only now beginning to take effe It has always been their practi value, as means to another end, th has made such language pedago cally important and brought them the foreground in the eyes of the g eral public. A living language h one inestimable advantage: that can become acquainted with it in its accentuations and modulations, all its insinuations and connotatio which are more important sometim than the actual word. The dead la guages we still must study, not on to understand the living historica but to observe their own and perha different place in a different stage civilization. All this infinite co parison is necessary in order to deci some day in how far we *can* spe as we think, and in how far we *mu* think as we speak.

American Interest.—In Ameri the tendency to this broader inter in language is showing itself in th ways: by publications on the general aspects of language, by the formation of the Linguistic Society of America, both discussed by Dr. Kent above; by an increasing study of American Indian languages; and by an interest, still nascent, in the languages of the Far East. A force less tangible is the attitude of investigators towards their subject-matter. Under the auspices of the American Council on Education a "Modern Foreign Language Study" is being made on a plan similar to that completed for Latin. Perhaps this will show us whether the academic emphasis on modern languages today is more than practical, or whether here lurks also a feeling for the finer shades and more exact results made possible by the presence of the living subject.

Indo-Germanic Group.—*Germanic Languages.* The greatest amount, as well as the greatest number of contributions and greatest diversity of subject-matter, will, no doubt, always be found in the native language. We have books on the "best" English both from the English and the United States' point of view, colloquial English, slang, pronunciation, Anglo-Saxon; articles semantic, morphological, lexical. A growing interest in place-names should be noted. Considerable interest in American English is evident, a subject on which Chicago University and the Modern Language Association have both undertaken an extended investigation. Meanwhile the first number of *American Speech* appeared in October. There is no work, however, that stands out preëminently as does Flom's *Language of the Konungs Skuggsja.* With many other contributions and reviews Professor Flom has kept the place of Scandinavian languages and scholarship constantly before us. German contributions have been meagre. We should note, however, the very laudable beginning made by Lambert in gathering and interpreting the non-English words in the Pennsylvania dialect. We have here an opportunity of linguistic research which we do not yet fully realize: of observing "language in the making," or, if you will, already made; at any rate, so new that most of the operations are still transparent. But we should also list the English words in such dialects and the frequency of both, and look likewise for grammatical forms and especially for syntax. Then we shall perhaps see some of the practical advantages that the one language or the other had among the early settlers.

Romanic language study is chiefly represented by the two volumes of Karl Pietsch. This is an old translation (1313) from French into a language fundamentally Castilian "with Portuguese-Gallician and Leonese elements."

Slavic is not represented this year by notable works; this is an indication of how dependent our scholars are on their pedagogical activity.

American Languages.—Besides the dialect of the Pennsylvania settlers we have within our doors scores of aboriginal languages, the languages of the Red Indian. Some of these are rapidly dying out; all, no doubt, rapidly changing. They are so different from our Indo-Germanic languages as to be well-nigh incomprehensible. The careful and persistent work of the present school of investigators, judging by Professor Boas' *Introduction* to the first volume of the *Smithsonian Handbook*, promises to take us a good way in the right direction. Owing to lack of funds the second volume was delayed till 1922. The material for a third is said to be ready. We may be thankful to Miss Reichard for rescuing from oblivion and establishing several matters in the language of the Wiyots. She made several trips, she tells us, seeking with much care the last speakers of this language, who seventy-five years ago were said to number a thousand. Mingling with other tribes, they adopt their language, so that it is very difficult to find some one who speaks pure Wiyot. This is the most recent of the invaluable series of monographs on American Archæology and Ethnology published by the University of California. *Language*, too, publishes a valuable article on Mexican Indian languages, indicating at the same time the importance of these inquiries and the breadth of its policy.

BOOK PUBLISHING

By Francis G. Wickware

Editor, D. Appleton and Company

Sources of Information. — Few large American industries are as badly served as book publishing in the matter of statistics properly classified and sufficiently trustworthy to reveal major trends in production and consumption. As to the actual distribution of books, which is the real measure of reading interests and the final test of publishing success in satisfying them, no figures whatever are available. The biennial Federal census of manufactures, by persisting in lumping books with "pamphlets" in its schedules of printing and publishing, gives only general indications of the volume of book manufacture. And the Register of Copyrights reports no classification of the printed volumes entered for copyright which segregates new trade books or gives a subject grouping of new publications.

The lists issued currently in the *Publishers' Weekly*, the organ of the American book trade, are the only available source of reasonably complete and accurate data of the number and classification of new publications of more than ephemeral or local interest. These lists are compiled mainly from books or descriptions of books supplied by the publishers for record, supplemented by scrutiny of the bibliographical cards on new copyright entries distributed by the Library of Congress. They record a close approximation to the total output of American publications intended for general distribution through ordinary trade channels.

The tables below show also that in proportion to population the output of new publications in the United States is comparatively small. It is a common complaint that too many books are being published, and with it goes the implication that each year brings forth a greatly increased flood of new titles. American publishers can at least retort that both in numbers of new books issued and in rate of increase they are exercising much more restraint than their European confrères. The fact is that the number of new books issued in 1924 was below the output of 1904 and the 13 following years, and that it is only after 1921 that the annual issues of new books have exceeded since the War one-half the record output of 1910. The figures as recorded in the *Publishers' Weekly* since 1900 are as follows:

The *American Booktrade Directory* for 1925 lists 676 publishers in the United States. Probably less than a quarter of them, however, contributed more than 5 titles each to the 1924 totals of new books and new editions. The largest contribution of a single publisher to these totals was 539 titles, and the second largest, 365 titles. Three publishers contributed between 200 and 300 titles, and 11 between 100 and 200. These 16 houses issued 42 per cent. of the year's output of new books and new editions.

International Comparisons. — The total of 6,380 new books issued in the United States in 1924 was less than 55 per cent. of the output of the record year 1910, when the *Publishers' Weekly* recorded 11,671 new book titles. For the United Kingdom, however, the grand total of 12,706 publications in 1924 established a new record, higher by 327 titles than the output of the previous record year 1913. Comparisons between the totals of new publications in the two countries must be drawn with caution, for the standards of the British trade organ are somewhat less exclusive than those applied to the American compilation. Nevertheless the 1923 and 1924 figures clearly indicate that British publishing enterprise has fully recovered from the difficulties of the War and the following economic depression.

ANNUAL ISSUES OF NEW BOOKS IN THE UNITED STATES SINCE 1900

1900	4,490	1913	8,687
1901	5,496	1914	8,513
1902	5,485	1915	6,817
1903	5,793	1916	7,219
1904	6,971	1917	6,798
1905	7,514	1918	5,709
1906	6,724	1919	4,772
1907	8,925	1920	5,101
1908	8,745	1921	5,438
1909	10,193	1922	5,998
1910	11,671	1923	6,257
1911	10,440	1924	6,380
1912	10,135	1925 (11 months)	6,278

Parenthetically it may be noted that books by American authors were only 53 per cent. of the new books and new editions published in this country in 1900. During the following decade the proportion rose to 68 per cent. in 1910, and in 1915, the first year of the War, it was 85 per cent.

The proportion has receded slowly since the War, reaching 81 per cent. in 1920, but it is safe to predict that henceforth American authorship will supply at least three-fourths of the books published in the United States.

NEW PUBLICATIONS IN 1925

The final figures of new publications of 1925 will show substantial increases over the 1924 totals. The new books recorded by the *Publishers' Weekly* during the first 11 months totalled 6,278, and, judging by other Decembers, the total for the year will probably equal that of 1906 though still falling below that of 1904. The 1925 record of new publications by months was as follows:

	Total (11 months)
New publications:	
New books	6,278
New editions	1,403
Pamphlets	1,310
Total	8,991
Origin:	
American authors	6,829
English and other foreign authors	2,162

CLASSIFICATION OF NEW BOOKS BY SUBJECTS
January-November, 1925.
(*The Publishers' Weekly.*)

Philosophy	201	Business	190
Religion	664	Fine arts	137
Sociology	374	Music	69
Law	116	Games	98
Education	161	General literature	291
Philology	177	Poetry; drama	497
Science	273	Fiction	870
Technical books	289	Juvenile	432
Medicine	194	History	337
Agriculture	84	Geography; travel	309
Domestic economy	37	Biography	444
Miscellaneous	34		

At the end of November, religion, law, philology, agriculture, music, games, and biography had already exceeded the figures of 1924, and sociology, education, science, poetry and drama, fiction, and geography and travel were only slightly behind. Substantial increases are indicated in all these classes; business seems to be the only class likely to record a substantial decrease.

Classification, Years 1900–1924.— Fluctuations from year to year, however, are of little significance as indications of permanent shifts in reading interests. Even over long periods there are few important changes in the relative numerical importance of the various classes of new books. This is illustrated by the following percentage classification of the new books published in the United States in 1900, 1910, 1920, and 1924:

CLASSIFICATION OF NEW BOOKS BY SUBJECTS IN PERCENTAGES
1900-1924
(*The Publishers' Weekly.*)

Classification	1900		1910		1920		1924	
	Number	Per Cent.	Number	Per Cent.	Number	Per Cent.	Number	Per Cent.

Fiction.—It is a second common complaint that fiction is absurdly predominant in contemporary publishing. As the form of recreational reading of widest appeal, the primacy of fiction in the classification of annual issues of new books is rarely challenged. Yet this table shows that in normal years the proportion of fiction is fairly stable at about 14 per cent. The low of 1910 and the peak of 1920 were due to more or less temporary causes; the end percentages of the 25-year period are practically the same.

Religion.—Religion, always prominent in the classification, now ranks next to fiction, and the two classes together account for nearly one-quarter of all the new books published. Philosophy in the quarter-century has practically doubled its proportion, and poetry and drama has steadily advanced from ninth place to fourth. Business now ranks with other professions in having a literature of its own. Law and education show startling declines, but it is probable that the declines are in large part fictitious, due to closer classification in the later years.

History and Kindred Subjects.—While the proportion of fiction has remained practically stationary during the quarter-century, the proportion of non-fiction books in the classes serving the interests of the general reader has increased by nearly one-half. The new titles in history and biography together now practically equal the output of fiction; the addition of geography and travel and poetry and drama gives a total of books for the general reader almost double the fiction titles. In 1900 these four classes constituted 17.5 per cent. of the year's total output; in 1924 the proportion was nearly 25 per cent. Here is clear indication of a growing interest in the more serious forms of recreational reading.

That there is a decided shift of reading interest towards these non-fiction classes, all general publishers are aware, and their lists are responding to the demands of the changing public taste. More impressive evidence of the extent and direction of the change would be supplied by properly classified census figures of book manufacture. The census classification is not nearly so detailed as the international classification followed by the *Publishers' Weekly*, and the inclusion of "pamphlets" with books limits the value of the census figures as indicators of trends in the demand for books. Still, there are in the following figures for the census years 1914, 1919, and 1923 some suggestions of interest.

Probably not half the annual totals are books. Still, it is noteworthy that, though it has increased 25 per cent. since 1919, fiction in 1923 was still 25 per cent. below the production of 1914; that juveniles trebled in the 9-year period; that religion and theology doubled; that history increased more than 150 per cent; and that total production in 1923 was double that of 1914. Our people are reading more, and they are reading more serious books.

CLASSIFICATION BY OUTPUT

PRODUCTION OF BOOKS AND PAMPHLETS IN THE UNITED STATES

Census Years 1914, 1919, 1923

Census Classification	Number of Copies Manufactured		
	1914	1919	1923
Fiction	39,598,501	24,317,643	30,014,162
Juvenile	16,399,881	24,434,912	49,679,895
General literature *	....	....	61,915,885
Poetry and drama	1,926,892	2,682,568	2,985,271
History	2,458,912	6,280,483	6,457,303
Religion and theology	24,411,502	36,496,230	48,193,861

Law	1,701,602	2,254,861	3,662,777
All others	37,599,887	80,526,784	60,002,141
Total	175,166,698	252,068,816	359,391,018

* New classification in 1923, mainly drawn from "All others."

Book Prices. — This is notwithstanding that book prices are considerably higher than prevailed before the war. These higher prices are a third grievance commonly expressed against American publishers. Yet figures compiled by the National Association of Book Publishers in 1925 show that since 1914 the cost of composition has increased 78 per cent.; electrotyping, 100 per cent.; paper, 79 per cent.; press work, 186 per cent.; and binding, 18 per cent.— an average of 91 per cent; while the retail price of the average book has been increased only 55 per cent., notwithstanding a concurrent increase in the discounts allowed to booksellers. Publishers are working on a much smaller margin of profit than before the War, and the soundness of the industry rests on the facts that fewer books are being published and more books are being sold.

DIVISION XXXVII
THE ARTS

PAINTING

BY LEILA MECHLIN

SECRETARY, AMERICAN FEDERATION OF ARTS

Present Tendencies.—Progress cannot be measured by activity; but activity undoubtedly evidences life. This being true, American painting during the year 1925 has given abundant token of robust vitality. Furthermore, and this is exceedingly to its credit, the dominant note of American paintings as shown in current exhibitions during this twelve-months' period has been cheerfulness, and cheerfulness based on a healthy outlook and technical proficiency. The so-called Modernists were a gloomy lot and their works for the most part stressed ugliness rather than beauty. The reason for that movement was, no doubt, the fact that the pendulum had swung too far toward weak prettiness. Be that as it may, these madmen have rendered a service to contemporary painting by jarring the painters out of old ruts and inducing bolder and simpler expression. The majority of the paintings seen today in the great exhibitions are colorful, frank, concise statements, which get their message over very directly and not only please the eye but command respect. They indicate individually a youthful, vigorous outlook, a sensitive appreciation of beauty and particularly of color values; and, as a whole, an amazing amount of technical skill on the part of the painters. Among the notable occurrences in the field of painting in America this year which will set it apart permanently, the following deserve special attention.

Sargent.—April 15, the world was shocked by the announcement of the death of John Singer Sargent, one of the greatest portrait painters of our day, who died in his sleep at his London home. He was about to sail for the United States to attend certain ceremonies held by art organizations and associations, among which was the unveiling of his recently completed mural paintings for the Boston Museum of Fine Arts.

Sargent was born in Florence, Italy, in 1856, the son of Dr. Fitzwilliam S. Sargent of Boston, physician and author; and Mary Newbold, a member of a Philadelphia family. He never renounced his American citizenship, though he lived almost continuously abroad. His funeral, which was at his London home, was marked by great simplicity. The burial took place at Woking, 20 miles from London, in a picturesque country district. A memorial service was held for him later in Westminster Abbey. A memorial tablet to him is to be placed in St. Paul's Cathedral, London.

Through the generosity of Sir Joseph Duveen a new Sargent wing is being added to the Tate Gallery of London. This will contain all of the Sargent paintings in the possession of the British Nation, including, it is understood, the Wertheimer portraits from the National Gallery.

A memorial exhibition of Sargent's works was held in the Museum of Fine Arts, Boston, in November, at which time the mural decorations already referred to were unveiled. A handsome illustrated catalogue was published.

Other Losses.—In this same field other serious losses must be recorded. George Bellows, a dominant figure among American painters of the present day, died January 8, 1925, at the age of 42 years, after a short illness. A memorial exhibition of his works was held at the Metropolitan Museum of Art, New York, during November, at which time was issued a beautiful catalogue reproducing all of the works shown.

Willard L. Metcalf, the well-known landscape painter, died March 9. An exhibition of Mr. Metcalf's paintings was shown during the month of January in the Corcoran Gallery of Art, Washington.

Dwight W. Tryon, also distinguished as a landscape painter, died July 1, 1925. His estate was left to his widow during her lifetime. At her death it is to go to Smith College for the purpose of founding an art gallery there.

Centenary Exhibitions.—The National Academy of Design celebrated the centenary of its founding by an exhibition comprising paintings and sculpture by deceased and living members which was opened in the Corcoran Gallery of Art, Washington, on October 18, by the President of the United States, and was visited by 70,000 persons during the four weeks it was there on exhibition. From December 2 to January 3 the exhibition was shown in the Grand Central Galleries, New York. An elaborate illustrated catalogue was issued in connection therewith. For this exhibition Edwin H. Blashfield, President of the Academy, painted a large allegorical picture, "Academia."

Inness Centennial.—The centenary of the birth of George Inness was also celebrated this year; he was born at Newburgh, N. Y., May 1, 1825. In recognition thereof a loan exhibition of about thirty of his paintings, ranging from the '60's to his last period, was held in the late winter at the Macbeth Galleries, New York. Much of Inness' life was spent at Montclair, New Jersey. It was fitting, therefore, that on May 3 there should be held at the Montclair Art Museum a celebration commemorating the 100th anniversary of his birth. Here, too, a group of his canvases was exhibited. Edwin H. Blashfield, the President of the National Academy of Design, presided at the meeting.

In further recognition of this great event a memorial was dedicated on May 1 at Tarpon Springs, Florida. This took the form of a hall, in which exhibitions, music and other entertainment may be given. It was at Tarpon Springs that Inness spent many of his winters and painted some of his best pictures.

Five towns of North Dakota also celebrated the Inness Centennial by exhibitions of reproductive prints and special programs in the schools and colleges.

Other Exhibitions.—Witnessing to a lively interest in the art of painting and in appreciation of the best, mention may be made of a comprehensive exhibition of portraits by John Neagle (1796-1865) held in the Pennsylvania Academy of the Fine Arts through the coöperation of Mantle Fielding, from April 12 to May 13. This comprised 125 paintings lent by their several owners. An elaborate illustrated catalogue was issued.

A loan exhibition of Old Masters was held in the Carnegie Institute, Pittsburgh, from April 30 to June 5. These were drawn from twelve private collections.

A notable loan exhibition of Early American Portraits, Miniatures and Silver, assembled by a local committee, was set forth in the National Gallery of Art, National Museum, Washington, during the month of December. This was one of the most comprehensive exhibitions of the sort which has yet been held, and laid further emphasis on the value of, and increasing interest in the works of the early American period.

A notable loan exhibition of Dutch and Flemish paintings was held at the Detroit Institute of Arts in January.

Foreign Artists. Quite a number of foreign painters exhibited in the United States under the auspices of our several art museums during the year. Among these were Zuloaga and Anglada, Spaniards; Anders Zorn, deceased; and Count Louis

Sparre, of Stockholm, Sweden; Savely Sorine, a Russian artist; and Anna Ciardi, an Italian painter, and the brothers Zubiaurre, painters of Basque scenes. Besides which mention should be made of an exhibition of British art, retrospective and contemporary, held in the Grand Central Galleries, New York, under the auspices of the English Speaking Union.

Mural Paintings.—A number of important mural paintings were unveiled during the year, in addition to the Sargent series, to which reference has already been made. These comprised four huge lunettes by Jules Guérin in the banking room of the Union Trust Company, Cleveland, and a series by the same painter in the banking room of the Illinois Merchants Bank Building in Chicago.

Twelve large mural paintings by John W. Norton, depicting the evolution of man, were placed in Beloit College, Wisconsin, and dedicated June 20, the gift of Frank G. Logan, Vice-President of the Art Institute of Chicago.

A painting by Lee Woodward Zeigler, representing Maryland, was placed in the lobby of the Maryland Institute and unveiled at the Institute's Centennial Anniversary Celebration in June.

Mural paintings by George Laurence Nelson were unveiled at Public School No. 40, in the Bronx, New York, in the same month.

A series of mural paintings by George Obertauffer were placed in the Children's Room at the Art Institute of Chicago.

A series of nine mural paintings by William Clark Rice, entitled "The Procession of the Fashions" was presented to the Jonas Bronck School (Public School No. 43) New York City, during graduation exercises in June.

Sponsored by the Philadelphia Art Alliance there was unveiled in the new Walt Whitman Hotel in Camden, New Jersey, in September a mural painting by Robert E. Johnston, entitled "In a Dream I saw a City Invincible." This is a symbolic composition, the outstanding feature of which is the figure of the "good gray poet."

The Society of Mural Painters assembled and sent out as a travelin exhibition a comprehensive collectio of mural paintings, not only b Americans but by the leading mura painters of Europe. This opened i the Brooklyn Museum in February

At the annual meeting of the American Institute of Architects held i New York in April, the medal fo mural painting was awarded posthumously to John Singer Sargent Edwin H. Blashfield delivered a eulogy on the great artist. Th award for Mr. Sargent was made t Mr. Guy Lowell, a distant relative.

Fellowships and Medals.—The fellowship in painting of the American Academy in Rome was awarded t Michael Joseph Mueller of Durand, Wisconsin, a student of the Yale University School of Fine Arts, for a painting entitled "Eternal Life." The jury of award was composed of Edwin H. Blashfield, Ezra Winter, Eugene Savage, Francis C. Jones and Douglas Volk.

At the annual meeting of the American Academy of Arts and Letters in November the medal of the Academy was awarded to Cecilia Beaux for her distinguished work in painting. This is the first time that this medal has ever been awarded for painting.

Among numerous important purchases of paintings and gifts of paintings recorded during the past year are the following:—The Friends of American Art presented to the Art Institute of Chicago five important paintings. The John Herron Art Institute of Indianapolis received as a gift from the Friends of American Art of that city a "Portrait of Margaret MacKittrick" by Abbott H. Thayer. The Albright Art Gallery, Buffalo, purchased a painting by Abbott H. Thayer entitled "The Boy and the Angel," at a cost of $40,000. The Boston Museum of Fine Arts acquired by purchase the painting by George Bellows entitled "Emma and Her Children." The Metropolitan Museum of Art received as a gift from Mrs. E. H. Harriman a painting by Max Bohm entitled "The Evening Meal." The Museum also purchased a painting by John C.

Johansen entitled "Evening." The Telfair Academy of Arts and Sciences of Savannah, Georgia, purchased a painting by Robert H. Nisbet entitled "The Hurrying River." The Carnegie Institute, Pittsburgh, purchased a large painting by Zuloaga entitled "The Castilian Shepherd." The Cleveland Museum of Art purchased a portrait of Mlle. Jeanne Balzac by Eugene Speicher. The Cedar Rapids Art Association purchased a painting by Frederick C. Frieseke entitled "Before the Window" Not to mention all. One of the record gifts of the year was that of paintings by great masters to the Metropolitan Museum of Art, New York, by Archer Huntington. The Ranger Fund, which purchases regularly a certain number of paintings by American artists, acquired during the past year the following works: "The Prodigal Son," by Horatio Walker, N. A.; "The Wood Card," by Louis Paul Dessar, N. A.; "A Reading," by Thomas W. Dewing, N. A.; "Dawn," by Dwight Tryon, N. A.; "The Storm Birds," by Armand Hanson; "Helen," by Jerry Farnsworth; and "Across the Valley," by Hobart Nichols, N. A.

Exhibitions.—The number of exhibitions of paintings seems to have increased rather than diminished, which is perhaps reasonable, as the number of painters has increased. The American Art Annual lists approximately 1,000 more painters this year than last. This list was compiled from those who have exhibited during the past two years, and from lists of members of recognized art societies. Royal Cortissoz in the "Field of Art" department of *Scribner's Magazine*, called attention during the year to the increased popularity of the one-man exhibition. It is worth noting that sometimes as many as twenty such exhibitions open simultaneously in the dealers' galleries, New York. Many of these collections are sent on circuits throughout the country.

There is an increased popularity, also, to be noted in the traveling exhibition, the feasibility of which was definitely demonstrated by the American Federation of Arts some sixteen years ago. This organization alone has thirty or more exhibitions of paintings, as well as exhibitions of other works of art annually on the road. These go from Maine to California, from Minnesota to Texas. One of these exhibitions was shown in three or four of the Fairs in Canada during the season of 1924-25.

The record of the year in painting is therefore large, and the outlook for the future, it would seem, encouraging.

SCULPTURE

By Ralph Flint

Art Critic of the "Christian Science Monitor"

Stone Mountain. — Perhaps the most colorful incident of the year within the sculptural fraternity was the Stone Mountain controversy which resulted in the dramatic withdrawal of Gutzon Borglum from his herculean task of carving the huge Confederate Memorial in the granite flank of Stone Mountain near Atlanta, Georgia, and the subsequent appointment of Augustus Lukeman, born a Southerner, to carry on the work. It is not so often that a *cause celèbre* rises in the ranks of American artists, but when it does it curiously seems to center around some piece of sculpture. Just as London is enjoying its Epstein wrangle at the moment and causing a vast amount of publicity to be given the artist, so the Borglum incident turned the American searchlights on its sculptors to perhaps good advantage, since they are so often seen and not heard.

Saint-Gaudens' Diana. — Another picturesque incident of a sculptural nature which also brought forth a deal of public comment was the threatened destruction of the Saint-Gaudens' figure of "Diana," which had perched so many years atop the tower of the Madison Square Garden in New York

City. With the razing of this famous landmark, it seemed inevitable that the lovely, lithe lady of the tower should have to go the way of all metal, but fortunate provision was made and she is now in storage awaiting her future pinnacle on the reconstructed Garden tower that is to rise one of these days upon the heights where New York University is located. Then "Diana" will again be seen at a proper distance, since its construction, being of the bolted metal order, would not bear a closer inspection. This is a fine piece of reclamation and should cause the sculptural ranks to greatly rejoice.

Barnard Cloisters.—Another event of prime importance to the world of plastic thought is the transfer of the Barnard Cloisters of New York City with their wonderful treasures of Gothic Art to the safe keeping of the Metropolitan Museum of Art, to be maintained as a branch museum through the generosity of John D. Rockefeller, Jr. Thus the magnificent collection that this American sculptor has formed is to be preserved in the best possible manner for future generations.

Roosevelt Memorial.—Other events of a public nature include the placing of F. G. R. Roth's statue to Balto, the dog of Alaskan fame, in Central Park, New York City, and of the awarding of the competition for the Roosevelt Memorial in Washington to John Russell Pope, architect. Just what is to be done about the execution of this design is still problematical, since there are Governmental committees yet to be assured of its desirability as part of the present scheme for developing the city. Among the outstanding purchases of contemporary sculpture during the year must be recorded the transfer of Daniel Chester French's large marble group, "And the Sons of God saw the Daughters of Men that they were fair" from the Grand Central Galleries to the Corcoran Gallery of Art.

Exhibitions.—It is manifestly impossible to trace within this small space all the many exhibitions of sculpture that occurred throughout the United States during the past year; and since the most importa art is almost without excepti brought to New York for critic judgment, it is possible by going ov the events in the various New Yor galleries to gain a fairly comprehe sive idea of what has come to ligh during this period. One of the mo outstanding one-man shows of t year falls to the credit of Elie Nade man. This original and gifted scul tor provided New Yorkers with threefold treat, in which he unfolde his talents in classic, naturalisti and modernistic guise, and all withi his particular range of expressio In highly polished white marble had executed a group of amazing bold, large nude figures, most archa at times and yet wholly expressi of himself. Here was art of a highl stylized type curiously conforming t the modern demand for free and sen sitized creative thought. His po trait heads in wood, bronze, and ma ble were visions of haunting beaut particularly in the heads of childre where he combined design and repr sentation with consummate skill an insight. For pungent contrast h added a third group of the most mod ern sort, large sized caricatures o the present-day types to be found i the cabarets and dance halls, carve in wood with patches of paint applie here and there for facial tint or orna ment. These "boulevardier" puppet he has made to dance or sing, t promenade and pirouette with mos whimsical and amusing abandon, an while they are miles removed in senti ment from the portrait studies, the are of the same order of artisti achievement. On the whole this wa the banner exhibition of the yea among American sculptors, contain ing as it did the widest range o sculptural expression and the finest technical display.

Manship Marbles and Bronzes.—Paul Manship's exhibition, which pre ceded the Nadelman show at Scott and Fowles by a month, was also o prime importance, coming as it did after his three years' absence from the American galleries. Most of the work displayed was achieved during his recent European residence, and while it differed very little from the marbles and bronzes which he had exhibited before this time, yet he appeared to be forging ahead in his art. A maturing vision and a more delicate and sure touch were evidenced in the various pieces which he offered for public approval. A large classic group, as yet in colored plaster, was a dominant note of the exhibition, but it remained for a later viewing at the Grand Central Galleries to see this opus in a right setting. Mr. Manship had finally made a mate to his famous and long-admired bronze "Diana" in an "Actæon" and this was included among the figures shown. It is of a more involved and less inspired pattern than the "Diana" yet by itself is a work of much authority. Perhaps it was too much to expect that the seemingly unpremeditated rhythms of the "Diana" would yield a companion composition of the same quality. A large "Armillary Sphere" standing for "humanity and eternity" was one of the handsome imaginative designs, but it was in the portraits that Mr. Manship's fine talents predominated. His marble bust of the Marchioness of Cholmondeley is a radiant achievement, broadly characterized yet delicately felt in its detail. Portraits of John Barrymore, Miss M. Carey Thomas, and studies of several most engaging children were also exhibited at this time.

Fuchs' Exhibition. — One of the largest one-man shows ever held in New York occurred in May when Emil Fuchs took over the entire gallery floor of the Fine Arts Building for a considerable period and displayed an enormous aggregation of sculpture, paintings, etchings, etc. His sculpture occurred in many varied materials, and his subjects were of equal variety. Portraits of distinguished men and women, idealistic figures meticulously modelled in the nineteenth century manner, medals and bas-reliefs made up the plastic section of this retrospective exhibition, and proved the artist to be thoroughly at home in his extended craftsmanship.

Rosenthal Miniatures.—One of the most unique contributions to the season's roster came in the miniature sculpture of Louis Rosenthal (of Baltimore), in which the artist has evolved by a secret process of his own a method of hollow casting that would doubtless give the great Cellini a bad quarter of an hour. Mr. Rosenthal's figures are often but a half inch in height, yet in every minute detail they are perfectly moulded after the original wax model. Certain of his group pieces, such as his "Beethoven," have a score or more of figures introduced. This minuscule sculpture is not only of great rarity but of a very high artistic order.

Other Exhibitions.—Other exhibitors of note with individual exhibitions were Edward McCartan with a number of his smartly executed bronzes in the eighteenth century manner, Dorothy Rice with her ambitious groups and interpretations of New York City, Nancy Cox McCormack of Chicago with her handsome portrait busts among which the likeness of Mussolini was conspicuous, Philip S. Sears of Boston with a first public showing of his work, Nana Matthews Bryant also of Boston, Hunt Diederich, Harriet G. Bingham, Alfred Lenz, Harold Erskine, Eugenie F. Shonnard, J. B. Flannigan, Georg J. Lober, Oliver Naldarelli, and Carl Illuva. Jo Davidson exhibited a recent heroic bust of John D. Rockefeller to be placed in the rotunda of the new Standard Oil Building in New York City. Another item of interest to sculptors was the opening of the new court of sculpture at the Brooklyn Museum, a very handsome setting for its treasures in stone and bronze. The National Academy had two large exhibitions during the past year, the first being the annual Spring Academy at which most of the local men were represented, and the other the Centennial Exhibition which opened first in Washington at the Corcoran Gallery and later at the Grand Central Galleries in New York City. Here were examples of the art of all the great American masters, past and present. Herbert Adams, Augustus Saint-Gaudens, Charles Grafly, John Flanagan, Frederick W. MacMonnies, Lorado Taft, Edmond T. Quinn, and

Anna Hyatt-Huntington were well represented.

Architectural League Exhibit.—The Architectural League held its huge annual exhibition at the Grand Central Palace, and here many items of interest to the world of sculpture were brought forth. The annual foregathering of the Society of Independent Artists failed to evoke anything of particular consequence in the way of hidden sculptural treasure, but the similarly organized Autumn Salon of America, among its array of artistic odd-jobbers and loose-enders, unearthed some interesting sculpture treated in color by T. Trajan. The New Society, as always, presented interesting material, and among the sculptor members exhibiting were Gertrude V. Whitney, James E. Fraser, Chester Beach, and Stirling Calder. The Grand Central Galleries with its large list of sculptor members held a continuous salon of bronzes and marbles throughout the year, and carried great numbers of interesting pieces to such outlying parts as Aurora, Ill., Norfolk, Va., Nashville and Memphis, Tenn., Stockbridge, Mass., and Newport, R. I. The National Association of Women Painters and Sculptors had its annual exhibition in New York, and among the exhibiting members were Malvina Hoffman (a prize winner with her "Paderewski"), Lucy P. Ripley, Renée Prahar, Alice M. Wright, Harriet W. Frishmuth, and Brenda Putnam.

Art Students' League.—The Art Students' League held its Golden Jubilee Exhibition with many fine sculptural items displayed, and the annual Allied Artists of America likewise convened at the Fine Arts Building in New York. The American Numismatic Society held its second annual exhibition in its galleries adjoining the Hispanic Society's building on Upper Broadway; among the hundreds of medals and plaques from all over the world the Italian group came through a clear winner. For the second time a contest was organized for sculptors by a large soap-making concern, and hundreds of carvings in this unusual but sanitary medium were forthcoming, many of decided originality and done in many cases by very young children. While sculpture usually seems to take a second place in the large exhibitions to painting and the graphic arts, yet casting over this past year's output brings out the fact that the sculptors of the moment are well to the fore, and contributing their proper quota to the art of the year 1925.

ARCHITECTURE

By Charles Harris Whittaker

Editor, "Journal of American Institute of Architects"

General.—Two or three decades ago Europe was the architectural Mecca of the American people. This is not to deny the work of the small school of American architects that had already begun to make its mark, but rather to emphasize it, if that be possible. But, in considering the subject of education, for example, it is only necessary to remember that the École des Beaux Arts at Paris was the center around which Americans generally revolved, if they were interested in acquiring a knowledge of architectural design. To-day all is changed. American schools of architecture have outstripped the École des Beaux Arts, albeit no educator in America would withhold from the École its just due, for its influence has been paramount and its theories of teaching have had their ineffacable effect.

It is of course impossible to arrive at anything resembling a unanimous verdict in these matters—that is to say, whether the American-trained student has outdistanced his European-trained confrère, or vice versa. It all depends upon the point of view, for one training begets its prejudices quite as much as does the other. At any rate, it is worth noting that Europeans are now sending their architectural students to this country in increasing numbers.

Scholarships for architectural study in America have been founded and more are rumored. Draughtsmen are coming to America in search of that experience which they hope will help them to turn their own countries into successful competitors with the United States.

For the last decade the tide of foreign interest in American architecture has been rising with an almost incredible swiftness. Whether or no it has attained to flood has not yet been disclosed. But there hardly seems room for doubting that the foreigner is first of all caught by the amazing scale of American building. The skyscraper was of course the first note in this seven-league stride of the building industry, but in other directions the scale is likewise visible. Exhibitions of the work of American architects have followed each other in succession to different countries in Europe. In 1926, Berlin and Vienna will see a vast collection of photographs and drawings, and in far-away New Zealand, at Dunedin, the same year will witness another huge assemblage of illustrations of the work of American building designers. No architect will deny, I believe, that it was the element of scale which first began to set the tide of foreign interest mounting high, although this does not mean that American design is without interest, or that American technic is not a factor of the very greatest importance. For with scale there has also come speed. So vast are the sums required to finance the structures that now call for twenty millions where one million used to suffice, that a day's interest charges on the loans advanced is more than the payroll of an old-time contractor. The yearly interest charge would once have been deemed a fabulous price to pay for any building.

Scale.—Thus when one essays a view of modern American architecture it is impossible to avoid dealing with scale as a prime factor. During the last three decades, and since the complete victory of the steel skeleton type of building, we have witnessed such a competitive race in building heights as almost passes comprehension. Various causes are assigned. The island of Manhattan on which the biggest building orgy of all time has occurred is long and narrow. Thus it is said that buildings had to go up. But this is sheer nonsense, as any casual study of the built-up areas of New York City will reveal. Nor does the parallel hold good when examined in any other city. The tendency of people to herd and congregate is sometimes set forth as the ineluctable factor which has turned our urban simplicity of horse-car and hansom cab into a vortex of converging streams of humanity. But people do not willingly submit to the desperate living conditions now imposed in the large cities merely for the sake of being near each other. The reason for our unplanned and unparalleled urban growth must bear some relation to our land system and to our credit economy. It is to these two factors that we shall finally turn as we essay to find a way out of the bedevilled chaos that city growth is constructing.

To dissociate these phenomena from architecture would be like trying to estimate when to enter a shallow-channeled harbor without taking thought of the tides. Architecture is not the fiction it is supposed to be. Architects do not create it, in the sense that they are free men with white paper before them. Environment, time, place, circumstance, credit, land, materials, workmen, habits, customs—these are the things that definitely mould the architecture of any land and time. The architect may fall back upon inherited tradition or he may seek to evolve new forms befitting the new habits, the new customs, the new financial views of things or the new pecuniary canons of taste. But to these he must bow, so far as any ensemble is concerned, and whatever value may be placed upon the work of the architect in the United States during the last fifty years, as to his esthetic capabilities or his structural technic, there will very likely be charged against architecture the failure to coördinate and harmonize our chaotic urban growth.

Individualization in Building.—The charge will be unfair. The architect has been helpless except in the smallest of ways. Our urban growth has been as unplanned as well may be. On street systems designed for horse traffic; on lots designed for a maximum of six stories; on an urban territory that scarcely could take a breath between its transformation from farm to crowded street, we have allowed individualism almost unlimited play. The right of the property owner to develop his land as he pleased has slowly been abridged, it is true. One by one we have imposed restrictions. One by one the courts have sustained the legality of police power interference. Little by little the nature of the modern city has come to be understood, the danger of its unregulated growth perceived, the menace of congestion realized. The height of buildings has been variously dealt with, in various cities, and out of the effort to put a stop to the breathless flight of steel and stone, as land values rose and rose and rose, there has come zoning, a term applied first by the Germans, who conceived the idea of trying to cope with unchecked city growth by fixing a status of land use and building occupancy, in districts or zones.

Zoning.—It is yet too early to attempt any evaluation of the effect of zoning. So far there seems no reason to believe that it has produced any great effect. As a factor in stabilizing land values, it has its uses. But that is not what is needed if we are to temper the cityward scramble with some undertow. To district or zone a city or town by merely accepting present conditions and fixing them permanently is to fortify the present owners and handicap those of the future. If zoning be thought to prove a remedy for congestion, we may not derive much encouragement from the experience of New York, although the character of the congestion is no doubt changing. Is it for the better? Let us see.

Skyscrapers.—The American skyscraper is as much a Chicago invention, or more, as it is a New York idea. But New York has enjoyed the doubtful popularity of building the most and the highest. A decade ago, when the race seemed to be imperilling the life of the city beyond a point which could be sensed by a great majority of people, the arbitrary limitation of heights was imposed. (Already the limit on Fifth Avenue has been withdrawn.) Under the law it became necessary to set back the outer walls of the building as it rose in height; these set-backs varied with the width of the street, bordering open spaces, corners, parks, and so on. The architectural effect has been pronounced and bids fair to add a picturesque quality to such buildings as can be seen, either from near-by, which is now almost impossible, or from afar, which still remains one of the sights of all time as the newcomer to our shores sails up the harbor of New York.

But the picturesqueness accomplished by set-backs, which in turn produce towers or tower-like effects, has had another effect as well. It can readily be understood that on a small ground area the set-backs required after say twelve stories work a serious injury to the owner. His floor space for rental begins rapidly to diminish in area and as the elevators must be carried to the topmost story, no matter how small its area may be, the limit is quickly reached. With a high land cost the owner is forced to consider some way of joining his property with some other. Only so is it possible to build a structure that will pay an adequate return on its cost plus the cost of the land. Only so is it possible to carry buildings to the required height. Ground areas must grow larger. And with the added height comes added congestion and added land values, and thus a fresh cycle of rising heights and larger ground areas ensues. The city block is of course the present ultimate limit, but long before the city is covered with structures, of which only the streets are the surface limits, there will be, let us hope, a willingness to recognize the absurdity into which the city dweller is being pushed.

Process of Building.—Just as urban architecture is the chief consideration in a view of any given period in the present, just so is it useless to take no account of the real factors that are producing it. A twenty million dollar fifty-six story apartment house such as has been projected for the site of one of the old Vanderbilt mansions on Fifth Avenue is not the simple dream of an architect. Rather is it the result of forces far beyond the control of any set of men, as things are. The value of land sets the pace. Behind, with all the speed that may be summoned, follow the architect, the builder, the manufacturer, the inventor, the workman, the manager, and, last of all, the army of people that are bidden to dwell within. Basically a problem of finance, the process is almost like magic in its swift-rising steel framework, its astonishingly deft workmen balanced on beams or hanging suspended at dizzy heights, its walls taking flight not from the ground but from some story in the air. If we stand amazed at the ancient Egyptian process of raising the pyramids by inclined planes and levers, what is to be said of the bewildering maze of wire and pipe that is woven into the fabric of a modern urban structure? Of the miles of drawings, the reams of specifications, the masterful coördination of time and trade? Every minute counts, every hour is tuned to a calculated program, every day has its quota, every month its breathless summing-up, and at the end, in a space of time that is unbelievably short, the building emerges to take not its predestined place in a great architectural ensemble based upon convenience and safety and light and air, but upon the stage of congestion, that amazing vested interest which now enslaves us with its uncountable tentacles.

Yet this is not to deny to American architecture its increasing æsthetic interest. The foreigner, if he have any knowledge of America (and most of them have), will not need to be told the tale of Richardson, McKim, and Goodhue. He has been watching the evolution from afar, and he knows that the Renaissance is the period from which we are drawing most at the moment. If he did but remember, he might look at our modern system of architecture as essentially Byzantine, in that we cover our structure with a thin wall which permits a very great variation in color and pattern. This possibility we have not yet learned fully to make the most of, but we are gaining fast in our knowledge and in our daring. Color is fraught with a great fear to Americans, it seems, since we hardly dare to do more than give a dash of it here and there, but color is gaining ground, perhaps because of the fashion of illuminating buildings by night, and it seems not impossible that we shall some day emerge from our drab garments and put upon ourselves a raiment of brilliant and well chosen hues.

Examples.—The building of the American Radiator Company on Bryant Park, New York City, has attracted much attention by reason of the color experiments that have been made in its top stories. The note of black and gold is perhaps a bit fantastic for a building, a little too much like an over-dressed person on the street, but it has been the subject of much comment and criticism among those not primarily interested in architecture, and that at least is a healthy sign. The danger, of course, in any effort to be conspicuous, is the danger of being vulgar, and it must be remembered that the drama played by a building is rather permanent. It cannot be taken down and changed every little while. There it must remain, and therefore the achitect must be on his guard lest the temptation to dramatize, even for advertising purposes, lead him into a frivolity or a stupidity that will end by boring people to death. This danger is perilous when the scale of our modern buildings is considered, for although man has long since ceased to have any scale relation with his city street, or his canyon of façades, he is not unlikely to become resentfully aware of any effort baldly to "sell" him some commodity by the use of architectural trickery.

By the same token, one is at least not unfair in raising the question of the ultimate success of the new building for the *Tribune* in Chicago. The competition of 1923 attracted worldwide interest and although the weight of opinion seemed to credit Mr. Eliel

Saarinen with the best design, the award went to Messrs. Howells and Hood of New York. Completed in 1925, the structure takes its place among the skycrapers of Chicago, and raises its buttressed upper stories above the river on Michigan Avenue. But the question of its ultimate place is raised because of those very buttressed upper stories. The merest novice will surmise that the buttresses are unnecessary—that the tower would stand quite alone in its steel webbed strength—and hence he will ask (or will he?) whether it would not have been better to omit a form born of the masonry-walled Gothic and to have been honest in the structural exterior. But this is, at the present, an academic question only. Romance still holds some sway over us, and it is perhaps quite as reasonable to conclude that the sweep of the buttresses, reminiscent of some cathedral of the Old World, will long delight and soothe the Chicagoan. Time has its way of dealing with these things, and one can never do more than risk a prophecy, in the matter of a new building. Sometimes the risk is trifling. Few would hesitate to predict a certain and long-continued esteem for the Shelton Arms in New York City, of which Mr. Harmon is the architect. Beautifully studied in the mass, clean in its line, charmingly reticent in its ornament, there are not many modern urban structures that have outranked it in interest and favor.

Nebraska Capitol.—The year 1925 will scarcely witness the completion of the Nebraska State Capitol at Lincoln, for the great tower has yet to rise. But the main building will be finished early in 1926, it is expected, and already prophecy takes wings to itself and whispers in all our ears that the Nebraska State Capitol designed by the late Bertram Grosvenor Goodhue will stand as the first great American structure—that is, the first monumental building which will have no direct traditional relationship with the styles of past periods. Those who hold that architecture is a dynamic and not a static art seem to have an irresistible argument. If art—architecture—contained no vested interests and performance were judged on a pure basi of æsthetics quite divorced from al pecuniary factors and professiona frictions, then it would seem littl to risk in prophecying that Bertram Grosvenor Goodhue has bequeathe us a work of pure genius. For i was no mere accident that led him to design a towered rather than a domed capitol for a great agricultura state—a state without any æstheti tradition—a state of plains and long flat sweeps that ended only at th horizon. Calmly, surely, he tossed aside all the Gothic accumulation through which he had won his way to the topmost pinnacle of American architecture, and brought all his gifts to bear on the problem of mass and proportion, of a monumental styl free from petty ornament and fussy detail, of a great building poised perfectly in its own strength, free-standing, the symbol of a great state, o government, of organized law. Fortunately, his work was finished, al save the watchful carrying out of his plans, when he died suddenly in 1924 But the Nebraska State Capitol and the Los Angeles Public Library (under construction) are our recompense for the loss of the fruition of those dreams that were already shaping in Goodhue's mind as he looked forward to buildings ever more and more exquisite in the sheer loveliness of their simplicity.

Architects.—The year 1924 will long be remembered in American architectural annals, for within the space of a few months, there died Henry Bacon, Louis H. Sullivan, and Bertram Grosvenor Goodhue. All were men of renown and yet each had won his way over widely diverging routes. Bacon was a pure classicist, and his life work may be said to have culminated with the Lincoln Memorial at Washington. Louis Sullivan was the antithesis of classicism, a believer in the essential movement of architecture; that it is dynamic and not static, and that "every problem contains within itself the seeds of its own solution." His own autobiography is one of the great contributions to architectural thought and theory, and it will long remain as one of the clearest records of the child's mind that any man or woman has set down.

Bertram Grosvenor Goodhue was a pure genius. With so little schooling that it is not worth mention, he fairly burst into architecture with all the force of undauntable power. From the smallest of beginnings as an office boy in New York City, he quickly rose to partnership with Ralph Adams Cram, and then to the topmost heights. One risks little in prophesying for Bertram Goodhue the ultimate crown that American architecture has it in its power to bestow. From the exquisite mastery of Gothic he expanded to the simpler form, the studied mass, the undetailed façade, the unornamented structure. He began to see architecture as a sculptural whole, and little by little to infuse his designs with a quality that commanded the breathless admiration of his fellow practitioners. Dying at the age of fifty-four he left American architecture at the moment when his greatest dreams were but beginning to unfold.

Housing Problem.—It remains to consider one other element in American architecture. Since the war there has been much discourse of "housing." During the last few years there has been a coincidental real estate speculation the like of which the United States has perhaps never known. With this speculation there has also developed a medley of planning agencies, designed to furnish plans for small houses to the man of small means. But in 1923 and again in 1924 the Housing Commission of the State of New York called attention to the fact that as a result of its survey it was obliged to publish the information that less than half the people residing in the wealthiest state in the Union were enjoying a sufficient income to own or rent a decent house! Thus it is true that architecture, despite its fine achievement in scale, in the grandiose, in the monumental, remains helpless before a phenomenon that has fallen upon the United States just as it has fallen upon the Old World. Our cityward scramble does not make for a healthy development either of human beings or of architecture, and to discuss architecture without taking note of these things would be as idle as to discuss the Greek temple without discussing the Greeks of that day.

It is true that we are in the industrial era. Velocity is the order of the day. Speed is the disease which we mistake for a saving grace. Building has become a race, a battle with financial factors, a scramble to house more people on less land, to provide schools for the endless tide of children that seem to multiply as the sands of the sea. It has become a highly specialized piece of business all round. It has its serious problems, not only of labor but of technic. And, as has already been said, it is these problems, these needs, these dominating factors that lie quite outside of either labor or technic and are found in the abode of finance, that determine the quality and the style of American architecture. For the ultimate style will thus be developed. It cannot be shaped by any individuals. It cannot be imposed. It cannot be fastened on as a bit of decoration. Ultimately it will emerge as the faithful picture of the time and the habits and the customs and the destiny of the American people. It cannot be otherwise, for of all human records, architecture is the most vital and the most truthful.

LANDSCAPE ARCHITECTURE

By Aubrey Tealdi

Professor at the University of Michigan

The current year has shown a very marked increase of activity in all fields of Landscape Architecture, the reports from most of the professional offices indicating sustained interest both in public undertakings and private work. It is natural that with the constantly increasing public appreciation of the value of city-planning landscape architects should find themselves more and more concerned with comprehensive schemes in which landscape art finds full scope. The importance of great public parks and parkways to landscape art can not be overestimated because with very few exceptions it is only in these public undertakings that the designer can expect to have his plans carried out and developed to maturity.

Small Estates.—This is due to a tendency which has become more and more marked the past few years in the development of private estates. The era of the extensive estate of hundreds of acres seems to be passing and in its place we see a far larger number of smaller country places in which the scale of landscape development is necessarily much reduced and the style altered.

Public Parks.—If this tendency towards smaller country places is sustained, and both economic and social conditions would seem to suggest it, it is evident that the great landscape effects typified by Prospect Park in Brooklyn and Delaware Park in Buffalo which represent the finest conceptions of the earlier period of the landscape school would in the future be possible only as public undertakings. For the landscape architect this is not an unsatisfactory situation. The factor of time in landscape development is such an important one that continuity in ownership and policy is essential over a long period of time if a design is ever to mature. In all parts of the conutry a park department is now such a definite part of city administration that continuity of policy in park development can at least be hoped for, but it is impossible to hope for it where a private work is concerned when the tenure of a country place rarely extends over more than one generation.

Suburbs.—The ever increasing number of country places of a few acres is greatly extending the suburbs of all the larger cities so that we find the country place no longer merely the summer residence but the only residence of men whose business is in the adjoining city. The earlier d velopment of country life which w due to the advent of the railwa has given way to a more intensi development of suburban life due the general use of motor cars. T popularity of this suburban life further emphasized by the remar able increase in the number of e tensive country clubs that are bei developed. The landscape archite finds in this field also an opportunit for the practice of his art on a larg scale but only time will tell whethe real permanency can be expected i it.

Status.—In surveying the countr at large we can safely say that lan scape architecture never before he such a high position as an art of d sign as it does today. While course some poor work is being do today as always, the percentage good work is constantly increasin It would be rash to say that this wa due to the general improvement public taste. There are two definit reasons for it. The first is the eve increasing influence of the America Society of Landscape Architects whic has steadily exercised this influenc by insisting on constantly highe standards. The second is the de velopment of professional instructio in landscape design in Universitie and Colleges. Much work that year ago would have been left to th nurseryman or contractor is toda being undertaken by the graduate o the professional schools. Throug these graduates the influence of th schools is being spread widely i many sections of the country.

The Garden Club of Lake Forest Illinois, held a two-weeks' Institut of Landscape Design in July unde the direction of Ferruccio Vitale F.A.S.L.A. of New York. Lectures b members of the A.S.L.A., round tabl discussions, and organized visits t estates and gardens formed the basi of instruction. The institute wa well attended and it established a fin precedent for garden club activitie in the country.

University Instruction.—With th purpose of raising the standards an the efficiency of this instruction th teaching staffs of the several institutions initiated some years ago a yearly Conference of Instructors in Landscape Architecture. The Conference, which had been held previously at Harvard, Cornell, and Michigan, was held this year at Illinois. The most valuable results of these meetings have been the development of a spirit of coöperation among the various schools and the active cooperation with them of the American Society of Landscape Architects through its Committee on Education.

A number of books on subjects of interest both to the professional and the amateur were published this year. Those interested will find them listed and the more valuable ones reviewed in the quarterly publication *Landscape Architecture,* the official organ of the American Society of Landscape Architects.

CLASSICAL ARCHÆOLOGY

By William Nickerson Bates
Professor at the University of Pennsylvania

Corinth.—The year 1925 has been an interesting one in the field of Classical Archæology. At Corinth, where the American School of Classical Studies at Athens has been excavating for about thirty years, Dr. T. Leslie Shear of Princeton resumed work in the ancient theatre. He found that in Roman times the two front rows of seats were removed and this space, together with the whole orchestra, dug down to a lower level. This made a circular arena with a wall six feet high surrounding it. The inner side of this wall was brilliantly painted with life size figures of gladiators engaged in combats with animals, showing that the arena was intended for gladiatorial combats. The mass of earth above it is so great that it was possible to uncover only a small portion of the wall, but work will be resumed upon it in 1926. It was also discovered that at a still later time the theatre was again rebuilt and the seats made to rise at an angle different from that of the Greek theatre. Some distance to the north of the theatre Dr. Shear partly excavated an important Roman villa. The floors of the rooms were covered with elaborate patterns in mosaic, some of which have been carefully copied in colors. Further work will be done on this site.

Athens.—The late Joseph Clarke Hoppin, who took part in the excavations of the American School at the Argive Heræum from 1892 to 1895 and published the Greek vases, planned a few years ago to dig deeper on that site, believing that still earlier remains would be uncovered. When it became clear that his illness would not permit him to do the work himself he provided funds for the purpose and after his death Dr. Blegen, the Secretary of the School, dug in accordance with his directions. Hoppin's predictions were fully confirmed. Masses of neolithic pottery like that previously found in Thessaly were unearthed and it became clear that the whole hill had been inhabited in neolithic times and down through the whole Bronze Age. One house of Early Helladic date (2500-2000 B. C.) and several Middle Helladic houses (2000-1600 B. C.) were found, all more or less injured, and ten Middle Helladic graves. An unsuccessful search was made for beehive tombs; but seventeen Mycenæan chamber tombs came to light dating from 1600 B. C. on. Repeated interments were made in these tombs. The first body would be carefully laid in the middle of the burial chamber, but when a later burial was made the bones of the first incumbent would be pushed aside and the new body placed in the middle. In one tomb there were five groups of bones dating from different periods as the vases found with them showed. This tomb was in continuous use for about 200 years. Five of these chamber tombs showed evidences of fire; in one case the layer of black ashes on the floor was from one to two inches deep. The most interesting small objects found in them were two bronze daggers inlaid with gold, similar to the daggers found in the Shaft Graves at Mycenæ but a little later. One has three doves (no two alike) in niello on each side; the other a dolphin on each side. Other small objects found were bronze spearheads, two gold necklaces, a carnelian pendant representing an elephant, seal stones, etc.

An important incident is the offer made to the School by the Greek Government in the spring of 1925 to grant it the privilege of excavating the site of the ancient market-place at Athens and the whole region to the north and east of the Acropolis. This is the most promising archæological site in Greece. The School has accepted the generous offer and will begin work as soon as the necessary funds are forthcoming. The government has already set a price on the buildings in the area and they will be condemned and removed as the work progresses.

Other Excavations.—The School has also had other excavations on hand. In 1924 the site of Phlius in northeastern Peloponnesus, where preliminary work was done by the School in 1892, was carefully explored. About eighty-five trial trenches were dug and the site of the theatre and other public buildings determined. An interesting feature was the discovery of a considerable amount of prehistoric pottery datin from the period of transition from n olithic times to the Bronze Age. Ne lithic sites in the Peloponnesus ar rare. The others known are at th Argive Heræum, two in Corinthia an one in eastern Arcadia. Some archai Greek inscriptions were also found.

Preliminary excavations were als made at Nemea, but they have no progressed far enough to make cer tain the identification of the wall uncovered.

No excavating has been done a Sardis since the Turks again obtaine control of the country; but in th summer of 1924 Professor D. M. Robinson and Sir William Ramsay du at Pisidian Antioch and brought t light architectural remains, sculptures and inscriptions, mostly of lat date.

Patrons.—Classical archæology ha suffered a grievous loss in the deat of four men who have attained distinction in that field. Professor Allan Marquand of Princeton was a eminent specialist in Mediæval and Renaissance Art; Dr. Joseph Clark Hoppin was the chief authority in the country on Greek vases; Richard B Seager for many years carried on excavations in Crete; and C. Densmore Curtis, long connected with the American Academy in Rome, was an authority on Etruscan and Roman antiquities.

ART SALES AND EXHIBITIONS

By G. A. Mock

Of the American Federation of Arts

General.—Those interested in the fine arts are apt to be interested as well in the prices they bring. Quotations from the open market are the only available check upon prevailing prices. In public auctions precedents in the matter of values are established almost daily; sometimes for the works of modern painters whose pictures have never before been publicly sold; sometimes for works of old masters, whose values may fluctuate until stabilized by the interest of an important sale. Records which cover a period of fifteen or twenty years when consulted will chart a practically steady rise with few deviations for the work of one master and some declines. Inexorably, one way or another, the records of works publicly sold mark the values in the fine arts field. For many years auction sales abroad have been carefully watched and accurately recorded. Now, when not only the works of art of our own private collectors but also the important works gathered by foreign collectors are, in so many instances, sent to New York to be sold, the fluctuations in values here are coming to be regarded with ever growing interest.

Ninety-two important sales, comprising entirely or in part objects of the fine arts were reported for the season 1924-1925. Sixty-two sales comprised in whole or in part paintings. Forty-six sales included sculptures and 5 included drawings, one being solely of drawings. Thirty-three sales were in whole or in part prints.

The auction season records the disposal of 4,108 objects of the fine arts for a total of $1,127,674. These figures include paintings and sculptures sold for $50 and over, prints and drawings sold for $25 and over. One thousand eight hundred and seventy-seven paintings sold for a total of $797,594. Six hundred and thirty-one pieces of sculpture brought $196,357; two hundred drawings brought $17,375; and 1,400 prints brought $116,338.

Paintings.—Among the outstanding sales taking place during the season 1924-1925 was that held December 10th in the American Art Galleries at which were sold paintings, sculpture with furniture, textiles, objects of art, being the private collection of lo Giacomo Nunes, Palazzo Orsini, Rome; it brought a total of $130,215.00. In Washington at Sloan's Art Galleries paintings and prints together with furniture and household embellishments from the estate of the Honorable Frank B. Brandegee were sold January 6th, 7th, 8th, and 9th. On January 14th, 15th, 16th, 17th, paintings and sculpture together with the objects of art from the private museum of the late Georges Spitz of Alsace, France, sold for $201,366.00, at the American Art Galleries. On January 23rd one hundred and two modern paintings of the French and American schools from the collections of the late Dr. George M. Minor, the late Joseph H. White and from other private sources sold at the American Art Galleries for $24,010.00. An important painting sale was that held in the Freeman Galleries, Philadelphia, January 28th and 29th, when one hundred and thirty-six paintings of the American and European schools were sold from the collections of the late Senator George T. Oliver, Pittsburgh, Pa.; John N. Bonham, York, Pa.; James Boyd, Harrisburg, Pa.; and from other sources. On February 4th and 5th paintings of the foreign and American schools including all the remaining works of the late Daniel Ridgway Knight and selections from the P. H. MacMahon, John Dugan and other private collections sold at the American Art Galleries for $14,717.50. On February 19th, 18th and 19th century paintings, the collection of the late Arthur Tooth, sold at the American Art Galleries for $57,840.00. On March 5th, at the Anderson Galleries, one hundred and fifteen paintings from the collections of the Hanover Club; Louis d'Aras, of New York; Mrs. C. S. Boker, of Seabright, N. J.; Mrs. Gertrude M. Smith, of Staten Island; and from the estates of Julia Chester Wells, of New York; H. Alloway, of Goshen, N. Y.; Helen Boyd Dull, of Harrisburg, Pa.; Wilmot L. Warren, of Springfield, Mass.; sold for $14,571.00. April 4th at the American Art Galleries, Gothic and Renaissance sculpture, primitive paintings, together with furniture, tapestries and Egyptian antiquities, the collection of Philip J. Mosenthal sold for $27,832.00. This sale was particularly noted for its interesting pieces of sculpture. April 30th and May 1st at the American Art Association, paintings and sculpture together with Gothic and Renaissance Italian and French furniture, textiles and objects of art, belonging to Pietro Cattadori of Milan, Italy, sold for $84,932.00.

Drawings and Prints.—An interesting sale of drawings was that containing several hundred by old masters from the collections of Richard Ederheimer of New York and the late Fairfax Murray of London, England, and which sold for $12,655.00 at the Anderson Galleries, November 6th and 7th.

Among the print sales of especial note was that of the collection of etchings by Buhot formed by Miss Myrtilla Daly Noe of Bayonne, N. J.; with mezzotints, etchings and engravings, including the collection of Mrs.

William B. Hayden of N. Y., which sold for $14,272.00 at the American Art Galleries, November 12th and 13th. The recent special interest in Currier and Ives lithographs is reflected in the number of sales recorded by the auction galleries. There were collections of them sold December 3rd and 4th, December 8th and 9th, January 6th, February 4th and 5th, February 12th and 13th, April 15th and 16th, May 1st.

Prices. — In reviewing interesting prices brought for single items it is to be noted that the highest price paid for a painting for the season 1924-1925 was $37,000.00 brought by the canvas "On the Dunes" (29 x 32) by the Dutch painter Anton Mauve. At the same sale, which took place in the Freeman Galleries, Philadelphia, "Nocturne—Return of the Laborers" (17 x 24½) by Jean Francois Millet sold for $25,000.00 and "Golden Autumn" by Pierre Etienne Theodore Rousseau brought $19,000.00. In January, which was several months prior to Sargent's death, a painting by him entitled "Barges at San Vigilio, Lake Garda, Italy" (22 x 18¼) sold for $3,600.00.

The highest price paid for a piece of sculpture was obtained by a work of the Italian School, 16th Century, entitled a "Pair of Çentaurs" (bronze, 12¾ x 14½) which sold for $4,100 at the Anderson Galleries. In the same sale a bust of Aristotle in bronze and marble (36 x 33), a work of the Venetian School, 16th Century, sold for $4,000.

"The Farmer's Stable" (mezzotint in colors, after Morland) by William Ward brought $1,000 which was the record price obtained for a print. It was sold at the Anderson Galleries in February. Among the Japanese prints the highest prices recorded were for a portrait by Sharaku purchased by the Walpole Galleries for $800 and a figure entitled "Standing Woman" by Kwaibetsudo bought by A. B. Duel for $675. "Sunset in Ireland," a drypoint by Sir Seymour Haden, brought $500, the largest figure paid for an etching. The highest mark for a Currier and Ives lithograph was $480 paid for "Home to Thanksgiving" (after Durrie).

At the Anderson Galleries the p and bistre drawing entitled "Ki Seated on a Throne" by Pietro del Francesca which sold for $1,500. marked the record for drawings f the season.

Exhibitions.—The general chara ter of the large formal and offici exhibitions held in this country du ing the season 1924-1925 was perha to be marked by the growing numb of international exhibitions and e hibitions which included works American and some foreign artist These joint exhibitions might be i terpreted as signifying a new assum tion of position by America in the a world.

One of the first large exhibitions start the season was the thirt seventh annual exhibition of Ame ican paintings and sculpture at th Chicago Art Institute. "Recessiona by Eugene F. Savage won the Fran G. Logan medal and $1,500; Malcol Parcell was awarded the Loga medal prized at $1,000 as well as th Norman Wait Harris bronze meda carrying $300 for his two portrait "Jim McKee" and "My Mother" Leon Kroll won the Potter Palme gold medal, with a prize of $1,00 for his painting of "Young Women" Charles Grafly won the Keith Spauld ing prize of $1,000 for his piece o sculpture "Study of Head of War" Jean McLane with her "Morning was awarded the Harris silver meda valued at $500.

The 100th anniversary of th Brooklyn Museum was observed i November with an interesting specia exhibition of paintings, sculpture, an prints lent by private citizens o Brooklyn, New York.

In the winter exhibition of the National Academy of Design the Car negie money prize was awarded t C. W. Hawthorne for his painting the "Captain's Wife." "Miss Ingram" by Childe Hassam was awarded the Altman prize of $1,000.

In January the New York Water Color Club and the American Water Color Society combined to hold a big exhibition in the galleries of the Fine Arts Building.

An art exhibit held under the auspices of the English Speaking Union of England and America was formally opened by Sir Esmé Howard, the British Ambassador, on January 10th in the Grand Central Galleries. The paintings shown were by English masters from Hogarth down to the present day.

In January in the Fine Arts Building, the Art Students League held a Golden Jubilee Exhibition to celebrate the fiftieth anniversary of its foundation. Many representative works by famous painters once students in the League were shown, together with examples by the student body of to-day. Also in January an international exhibition of mural painters was held in the Brooklyn Museum.

The 120th annual exhibition of paintings and sculpture opened February 7th at the Pennsylvania Academy of Fine Arts. The Beck gold medal was awarded to William James for the portrait of a woman; the Widener gold medal to Walter Hancock for "Toivo," the bust of a boy; the Sesnan gold medal to Frederick Bosley for an interior with figures "Elizabeth and Emily"; the Temple gold medal went to Clifford Addams for his painting "Washington Square, New York."

An exhibition of the paintings entered for the calendar competition held by Brown and Bigelow, in an effort to procure a better type picture for reproduction, was held in the Anderson Galleries in February. Louise Lyons Heustis won the prize of $2,500; $1,500 for the best story-telling picture went to E. W. Redfield for "Country Life in Winter"; Emil Fuchs won $1,000 for his "Modern Juno"; and Virginia Keep Clark was awarded a similar amount for the best mother and child subject. Gold medals were awarded Edward Dufner's "Two Intruders"; "The Circus" by Harold T. Denison; "The Black Hat" by I. H. Caliga; and "The Young Mother" by Edward F. Smith; silver medals went to the "Gateway in the Woods" by Charles S. Chapman; "Three Musketeers" by F. Luis Mora; "Mediation" by Juliette Thompson; and "Scarlet and Blue" by Hilda Belcher.

From February 22nd to April 6th an exhibition of the paintings of John Singer Sargent was held in the Grand Central Galleries. Some 70 canvasses were shown, making it one of the largest exhibitions of his work ever held in this country and making it a fine tribute to the painter in his own lifetime. Sargent's death occurred April 15, 1925.

The ninth annual exhibition of the Society of Independent Artists opened March 6th at the Hotel Waldorf-Astoria, with 760 artists represented by 1,180 exhibits, which made it the largest since its initial exhibition.

The "Hoosier Salon" sponsored by the Daughters of Indiana opened at the galleries of Marshall Field and Company in March. Over $4,000 in prizes were awarded. 208 artists were represented.

The National Academy of Design showed 422 works in its 100th annual exhibition which opened April 1st. The Saltus medal was awarded to John E. Costigan for his "Landscape with Figures"; the first Hallgarten prize went to Clarence R. Johnsons' "Lumberville Lock"; the second Hallgarten prize to Stanley Woodward for "Mid-Ocean"; Hobart Nicholl's "Across the Valley" won the first Altman prize; the second Altman prize going to E. L. Blumenschein for "Sangre de Cristo Mountains"; Gertrude Fisk's "Sunday Afternoon" won the Thomas B. Clarke prize; the Maynard portrait prize went to William Auerbach-Levy for his "Father and Daughter"; Jerry Farnsworth's "Helen" was the winner of the third Hallgarten prize.

The fortieth annual exhibition of the Architectural League was held this year in the Grand Central Palace. The League collaborated with the Institute of Architects in staging the exposition of architecture and the allied arts. Over eleven foreign countries sent the works of their foremost architects. Medals and prizes were awarded in the various departments of the exhibition.

A large memorial exhibition of the work of George Bellows, who died last January, was held in the Metropolitan Museum of Art from October 12th to November 22nd. It comprised paintings, lithographs and drawings and included examples from all periods of his career.

The twenty-fourth international exhibition to be held in the Carnegie Institute, Pittsburgh, opened October 15th and contained 488 paintings, making it the largest show but one ever given there. Henri Eugène Le Sidaner took the first prize of $1,500 for "Window on the Bay of Villefranche"; Ubaldo Oppi, of Milan, won the second $1,000 prize with a painting of a nude; Charles W. Hawthorne was awarded a prize for his "The Captain, the Cook, and the First Mate"; Louis Legrand got the first honorable mention and $300 for "In the Café"; honorable mentions were also given Henry Bishop, Rosalie Emslie, and Leon Kroll; Emily Court, English, won the prize of $500 given by the Allegheny County Club which was awarded for the first time.

The National Academy of Design celebrated the one-hundredth anniversary of its founding with a centennial exhibition at the Corcoran Gallery of Art, Washington, which was opened by President Coolidge on the evening of October 17th. An effort was made to represent the various phases of American art during the past hundred years, both in the exhibits of sculpture and paintings.

STATISTICS OF ART

By Frances R. Howard

Editor of the "American Art Manual"

Gifts, bequests and foundations amounting to almost $17,000,000 were made to art organizations throughout the United States in 1925. The largest of these were: the preliminary gift of $3,000,000 from Mr. and Mrs. Simon Guggenheim, to endow fifty fellowships for international study in the arts and professions; two notable gifts were made by Mr. John D. Rockefeller, Jr., to the Metropolitan Museum of Art, New York—one of Standard Oil Stock valued at approximately $1,000,000, and the other of "The Cloisters," in New York City, the collection of Gothic art assembled by George Gray Barnard, consisting of between 600 and 700 items of sculpture, painting and other work, and a fund for sustaining it. The Carnegie Corporation voted $360,000 to be distributed among twenty educational institutions or organizations which give instruction in the arts. The Corcoran Gallery of Art, at Washington, D. C., accepted the valuable collection of miscellaneous art works bequeathed by ex-Senator William A. Clark. The Boston Museum of Fine Arts received in all nearly $1,000,000, the largest single legacy being $250,000 in real estate from Alexander Moseley to form a permanent fund. Ten new galleries, an auditorium, a Gothic gallery and five class rooms were added to the Toledo Museum through the gift of $1,000,000 from Edward D. Libbey, late president of the Museum. The Museum also receives through the will of Mr. Libbey total bequests of $4,850,000. Davenport, Iowa, received from C. A. Ficke a gift of 330 paintings, valued at $500,000, as the nucleus of a public collection. The Memorial Art Gallery, of Rochester, N. Y., received $300,000 from Mr. and Mrs. James Sibley Watson for an extension. Mrs. Thomas Emery was the donor of $300,000 to the Cincinnati Museum for a new wing. The Art Institute of Chicago, Ill., received $100,000 to establish the James Nelson and Anna Louise Raymond Room. Two portraits, by John Hoppner, valued at $200,000, were given to the Pasadena, California, Art Institute by Joseph Tilt. The John Herron Art Institute, of Indianapolis, Indiana, received through the bequest of Mrs. Anna Delzell Hughes a piece of property valued at $250,000, the income of which will be used for the purchase of paintings, and the aid of women students in the Art School.

New museums opened included the Pasadena, California, Art Institute; the Wightman Memorial Art Gallery at Notre Dame, Indiana; the Yonkers, New York, Museum of Science and Arts; the Museum of Fine Arts at Houston, Texas; "Hamilton Grange," former home of Alexander Hamilton in New York City; the Grace Campbell Art Museum at Spokane, Washington; the Wagnalls Memorial at Lithopolis, Ohio, and the Fine Arts Gallery of San Diego, California.

Buildings of special architectural merit completed were: the Newark, N. J., Museum, Jarvis Hunt, architect; the Cleveland, Ohio, Public Library, Walker and Weeks, architects; the Kenneth Sawyer Goodman Memorial Theater in Chicago, Ill., Howard Shaw, architect; the Scottish Rite Temple, William B. Ittner, architect, the Masonic Temple, Eames and Young, architects, and the Federal Reserve Bank Building, Mauran, Russell and Crowell, architects, all in St. Louis, Mo.; the Fine Arts Gallery of San Diego, Calif., Templeton Johnson, architect; a replica of the Parthenon, at Athens, in Nashville, Tenn., Russell E. Hart, architect, sculpture on the building by Belle Kinney, Leopold Scholz and George Julian Zolnay; the Textile Building, Jardine Hill and Murdock, architects, the building of the American News Company, Russell G. Cory, architect, and the Barclay-Vesey Building, McKenzie, Voorhees and Gmelin, architects, all in New York City; the American Legion Headquarters Building at Indianapolis, Ind., of which Walker and Weeks were the architects.

War Memorials erected included a statue by Daniel Chester French, at Milton, Mass., illustrating the celebrated poem "In Flanders Fields;" Coolidge and Shattuck were the architects. Laramie, Wyoming, has a war memorial consisting of a cross surmounting a limestone shaft twenty-five feet high, at the base of which are grouped four figures in bronze. It was designed by Louis Milione, sculptor, and Thomas, Martin and Kilpatrick were the architects. At Providence, R. I., a bronze statue by Mrs. Theo. A. R. Kitson, to the "Heroes of '98," was unveiled. Also a memorial to veterans of the Spanish-American War, by A. G. Newman, was unveiled in Schenley Park, Pittsburgh, Pa. The Grant Park Stadium, "Soldiers' Field," was dedicated in Chicago, Ill. A War Memorial, by Maude Sherwood Jewett, was erected at East Hampton, Long Island, N. Y.; it consists of a granite stele in Gothic style, with a laurel wreath carved above. In Boston, Mass., a memorial tablet and doorway were dedicated to three members of King's Chapel who lost their lives in the Great War, the architect was Robert P. Bellows. A War Memorial was unveiled at the Fifth Regiment Armory, Baltimore, Md., consisting of bronze doors, lunette and accompanying tablets, designed by Hans Schuler.

Other notable works of sculpture unveiled during the season were: five busts of well-known Americans in the Hall of Fame of New York University—"Charlotte Cushman" by Frances Grimes; "John Marshall" by Herbert Adams; "Harriet Beecher Stowe" by Brenda Putnam; a replica of the Saint-Gaudens bust of "William Tecumseh Sherman"; and "Asa Gray" by Chester Beach. In the rotunda of the Gould Memorial Library of New York University, in the Hall of Remembrance of American Artists, the following busts have been placed: "Augustus Saint-Gaudens" by John Flanagan; "George Inness" by Hartley; "J. Q. A. Ward" by himself; "Frank Duveneck" by Grafly; "Henry K. Brown" by Bush-Brown; "Carroll Beckwith" by Brewster; and "Walter Shirlaw" by Bartlett. Paul Bartlett was also the sculptor of a bronze statue of Robert Morris, unveiled in Philadelphia, Pa. The "Pioneer Family," a fountain by Myra R. Richards, was unveiled in Indianapolis, Ind., as was also a fountain in memory of Mrs. Suemma Coleman Atkins. "The Man at the Wheel," a bronze figure by Leonard Craske, was unveiled at Gloucester, Mass., and is a memorial to fishermen lost at sea from 1623 to 1923. Attilio Piccirilli is the sculptor of the monument to Christopher Columbus, unveiled in the Borough of the Bronx, New York. In St. Louis, Mo., a large memorial fountain was unveiled, which is in commemoration of the services of two prominent musicians of the city, Owen Miller and Otto Ostendorf; it is the work of Victor Holm, sculptor, and Gabriel Ferrand, architect. An equestrian statue of General Sam Houston, by Enrico Cerracchio, was unveiled in Houston, Texas. In Washington, D. C., a panel, "Launcelot and Sir Ector," by John Gregory, was permanently placed in the Corcoran Gallery of Art. It is a memorial to the late Major William Corcoran Eustis. In Washington, also, a statue of General José de San Martin, the Liberator of Argentina, Chile and Peru, was unveiled. It is the replica of the statue in Buenos Aires by the French sculptor, Joseph Daumas. A bronze fountain group, "The Wine Press," by Donald Tilton, was recently unveiled in Golden Gate Park, San Francisco, California.

Museums Endowed.—In November, 1924, the people of Baltimore, Md., authorized by a large vote the municipal loan of $1,000,000 for the erection of a museum of art to be owned by the city. San Antonio, Texas, in the spring of 1925 appropriated $25,000 as the first installment of a future $100,000 museum, work to be started as soon as possible. "Kenmore," in Fredericksburg, Va., the home which Colonel Fielding Lewis built for his bride, Betty, the sister of George Washington, was dedicated as a national shrine by the Daughters of the American Revolution, on May 9, when practically all of the citizens of the town were in Colonial costume, and there was a parade of ancient vehicles. Songs were rendered by negro singers in Market Square, where tea was served by members of the Washington-Lewis Chapter of the D. A. R.

A Pan-American Conference on Capital Cities was held in Washington, D. C., in April, under the auspices of the Washington Committee on the Federal City, of the American Civic Association, and in coöperation with the Pan-American Union. The week before an International Conference on City Planning was held in New York City. In Philadelphia, Pa., in November, 1925, the sum of $1,000,000 was voted by the people to take over about two miles of the west bank of Tacony Creek for park purposes. In Washington, D. C., the National Capitol Parks Commission appropriated $600,000 for the purchase of park property in the District of Columbia.

The "Who's Who in Art" of Volume XXII of the *American Art Annual* contains the names of 7,383 sculptors, painters, illustrators, etchers, etc. This is an increase of 697 since the last directory of artists was published two years ago.

DIVISION XXXVIII
MUSIC AND DRAMA

MUSIC

By Frederick H. Martens

Contributing Editor, "The Art of Music"

General Survey.—What seems to be a definite post-war stabilization and prosperity during the year past has been reflected in music. Material gains include building of new auditoriums, concert halls and opera houses in various cities (New York, Albany, St. Louis, Salina and Kansas City, Omaha, San José), notably Mrs. F. S. Coolidge's new chamber-music auditorium at Washington, D. C., to which the Berkshire Festivals have been transferred. Increased prosperity has been felt in our music publishing business and the export trade in musical instruments. Greater general interest in music is shown in the foundation of many new choral societies, civic orchestras, municipal and other opera enterprises; and an increase in the number of music festivals and "music weeks" celebrated throughout the United States. Among bequests and foundations are: The John Simon Guggenheim Memorial Foundation; Bearns' Trust Fund (Columbia University); Caruso Foundation; Stony Point Opera Foundation; Juillard Foundation (fifty-one scholarship awards in 1925); the Pulitzer awards; numerous festival prizes and new scholarships; all endowments for pecuniary aid given American musical ideals and American musicians individually.

In moving picture music the original musical scores written by Deems Taylor to accompany "Janice Meredith," and by Mortimer Wilson for "Don Q" are outstanding individual contributions; while Erno Rapee's *Encyclopædia of Music for Pictures,* a catalogue of music essential for cinematic situations, deserves mention. Numerous new pageants were presented in the United States during 1925; and though *al fresco* music inevitably suffers in acoustic effect, the music in such pageants as the "Lexington Pageant" (Charles Repper) linking the battle with the present in historic tableaux; and "La Favorita de los Gatos" (Arthur Farwell), a pageant idealization of the *rancheria* life of Spanish California, may be instanced as typical of the quality of the American pageant score. In connection with pageants Roland Holt's *List of Music for Plays and Pageants,* tentative rather than comprehensive, is a useful publication.

In the field of mechanical musical reproduction the outstanding achievement of the past year is the Panatrope, recording and reproducing sound received from a telephone transmitter generating electric currents. Music is thus produced with a perfection of individual tone quality and shading exceeding that of radio transmission and other existing processes.

A direct stimulus to American composition in general during 1925 has been the activity of the National Federation of Music Clubs which at its biennial convention (Portland, Ore.) gave first performance to symphonies and operas by American composers.

Radio and Music.— Improvements in radio broadcasting during the year past have confirmed radio's position as one of the most powerful agencies for popularizing music in the United

States. Other contacts are immediate and personal, usually presenting the good, bad and indifferent with cheerful unconcern; but radio's advantages greatly outweigh its defects. Standard and new orchestral, choral and other music transferred directly to the average home by radio is a cultural and educational influence making radio's rôle of carrier of hotel and roof-garden jazz negligible. The "instantaneous" character of radio transmission is supported by the universal nature of an appeal which acquaints the radio owner with the news of the moment, and lets him participate in lectures, sermons, political and other conventions, *et al,* without leaving the room.

Radio and the American Composer.—In connection with the American composer, the most important radio development of 1925 has been the drafting of a new copyright bill to protect the composer's creative property. Phonograph and other mechanical reproduction companies at an earlier date had influenced the passing of laws compelling copyright owners to accept—in contravention to the general law of royalty equity—a negligibly small compulsory fee on each disk, roll, etc., manufactured by the exploiter, a fee far below a reasonable proportion to the latter's profits. The present effort to protect the American composer is due to the attempts of certain members of the tremendously wealthy group of radio corporations to ignore the common equity rights of the musical creator by evading payment of fee or license for their gainful exploitation of the products of the composers' brains.

The American Society of Composers, Authors and Publishers took the initiative in protecting the rights of the American composer and text-writer by calling public attention to the injustice done them. Independently of the Society Mr. Thorvald Solberg, Register of Copyrights at Washington since 1897, the leading copyright authority in the United States, undertook the drafting of a bill for a new copyright law which would deal justly with composer, text-writer, corporate interests and general public: in a word, with all concerned. The Society, without consultation with Mr. Solberg, and confident he would prepare a bill equitable from the standpoint of all concerned, pledged itself *in advance* to underwrite unconditionally (and did underwrite) any bill Mr. Solberg might prepare.

Meanwhile a radio corporation bill, the Dill bill, after much lobbying, had been drafted in Washington. Mr. Gene Buck, president of the Society, with a committee including John Philip Sousa, some of the best-known American composers and a group of the country's leading authors (for the Authors' League of America and other organizations had associated themselves with the American Society for the protection of the common property rights attacked) went to Washington. There Mr. Buck proved the justice of the Society's claims so completely that the bill sponsored by the radio interests was killed in committee.

Misleading propaganda to discredit the Society (and by implication the Authors' League of America) as greedy opportunists, eager to rob the American people of a source of legitimate enjoyment, has thus far failed. The composers and text-writers of the United States asked only what every "producer" in every other field receives, a fee or royalty on the profits made by those who exploit their prod-duct. Manufactures pay royalty to the inventor on his inventions. The music and words invented by composers and text-writers are, probably, the most valuable "raw material" used by the radio corporations. Air waves cost nothing and radio sets are sold at a high percentage of profit. To expect the American composer to turn over his musical ideas, his only source of income free to radio corporations whose exploitation brought them many millions of dollars was as unreasonable as to expect the Radio Corporation of America to distribute free radio sets or the American Telephone Company to supply service gratis.

The Perkins bill, a new form drafted by Mr. Solberg in 1925, aims to reform existing copyright law in such wise that all owners of copyright and the "small" composer, in particular, will be protected in their common equity rights. Its passage at the next session of Congress would be a notable ethical victory, would allow the United States to join in the Berne Convention, and would stimulate original creative effort throughout the country. At the Fourth National Radio Conference (November, 1925), the important equity principle "that owners of copyright were entitled to reasonable compensation for the use of their copyright" was agreed to by all interests; and the representatives of the radio broadcasting interests indicated their willingness to pay a reasonable charge for copyrighted numbers used by them.

American Opera.—The year 1925, like those preceding, has produced no great opera by an American composer. Frank Patterson's *The Echo* (Portland, Ore.) was a worthy symbolic prize opera; Charles Wakefield Cadman's *The Garden of Mystery* (New York) after a Hawthorne tale, interestingly scored, was given under circumstances which did not show it at its best; while Cadman's *The Witch of Salem,* announced for performance (Chicago, 1925), uses folk-tunes, Indian airs and a Madagassee pirate melody in telling a tale of witch-hunting days in New England. Francesco B. De Leone's *Alglala* (Chicago) makes vivid, colorful use of Indian thematic material in a tragedy of the Arizona Mesaland; while Ralph Lynford's *Castle Agrazant* (Chicago) is a genial musical handling of a Crusading tale. Both the last-named scores have been given locally: last year saw their first metropolitan première. At the New York Metropolitan, in the earlier part of the year, the Czech Janaček's *Jenufa,* a modern verist score preferring dramatic declamation to melody, was produced. Though a personal success for Maria Jeritza, who sang the title-rôle, it was not found musically compelling. A revival of Verdi's "Falstaff" called forth a sensational demonstration on behalf of the new American baritone, Lawrence Tibbett; but Montemezzi's youthful opera, *Giovanni Callurese,* despite interesting Sardinian folk-color, will hardly find a permanent place in the repertoire. *Flis* (The Raftsman) a *genre* opera by the Pole Moniuszko, sung in Philadelphia, was a pleasing folk-music score in the old style.

The first of the novelties announced for 1925-26 at the Metropolitan was Spontini's *La Vestale,* well staged and well sung, Rosa Ponselle creating the title-rôle. Though theatrically effective and musically noble it is too old-fashioned to appeal greatly to the general opera-going public. Cornelius' *Barber of Bagdad,* an Arabian Nights' tale to a tuneful, romantic score in Weber's style, is too undramatic for present day demands. Ravel's *L'Heure Espagnole* was a masterpiece of delicate, subtle orchestral tonal beauty and irony. It sets forth a realist tale of life in the eighteenth-century Toledo, whose heroine Concepción (Lucrezia Bori) in the absence of an elderly clock-making husband prefers the "native worth" of a muscular muleteer to the tender sighs of two physically lesser lovers.

"Jazz Opera."—Interesting is a group of 1925 scores which try to give the rhythmic and tonal effects popularly known as "jazz" artistic values as a valid expression of contemporory human emotion, social trends, etc. Isaac van Groove's opera *The Music Robber* (St. Louis) projects jazz backward, orchestrally and vocally ragged, into Mozart's life; Emerson Whithorne's futuristic ballet *Sooner or Later* (New York) uses "jazz" in a brilliant musical caricature of the "geometricized" life of the future; while John Alden Carpenter's *Skyscrapers* (ann. New York, 1925) represents "a musical-choreographic abstraction of contemporary American work and play 'noises,'" using jazz as a play noise. W. Frank-Harling's *A Light from St. Agnes* (ann. Chicago, 1925) employs Louisiana folk-songs and "blue" rhythms in a tragic verist presentment of modern jazz life in a Louisiana lumber village; and Lazare Saminsky's *Gagliarda of a Merry Plague* (New York) compresses two hours into twenty minutes in a clever modernist experiment in "chamber opera," with melody a secondary consideration, telling the tale of Poe's *The Red Death* with iron chains, strings of oyster shells and buckshot-filled tom-toms among its percussives.

General Considerations.—Increasing countrywide interest in opera during 1925 has been reflected by seasons in cities where opera had been unknown, and the activities of new opera companies on the Pacific Coast, in the South and in the Middle West. Native talent has produced notable work, but the value of extravagant propaganda for American opera along jingoistic national lines is questionable. In music, as in every other art, to use a homely apothegm, "Every tub must stand on its own bottom"; the flag painted on the tub's side is not material. American operas which musically measure up to those of Wagner, Verdi and Mozart or—aside from absolute musical values—voice the kind of theatric and popular appeal presented by Puccini, Massenet and Mascagni's one outstanding score, will come into their own without forcing. The past year has confirmed the world leadership of the Metropolitan Opera of New York with regard to the artistic luxury of its opera presentation, and the high individual quality of the singers of its company; and the year's most encouraging sign is the trend on the part of individual cities to set up their own opera, promising the American composer opportunities of performance which, should his works justify it, will compel later metropolitan production.

Symphonic, Choral and Other Novelties.—The United States is the world's musical leader considering the number of great solo artists, conductors, etc., appearing before the public. The multiplicity of concerts of every kind allows for mention of only a few more important novelties produced during the year. In the symphonic field have been heard: Henry Coswell's ultra *Ensemble*, in which the Indian "thunderstick," a whirring slab of wood, was used for wind effects as a background for string tone; Hendrick's *Suite Esthétique;* Aaron Copland's *Cortège Macabre;* Edgar Stillman Kelley's noble symphonic poem, *The Pit and the Pendulum;* Gustav Strube's *Lanier* Symphony; Howard Hanson's *Nordic* Symphony and Leo Sowerby's suite *From the Northland;* and the important symphonic poem *Jurgen* by Deems Taylor, a subtle and highly individual interpretation of Cabell's famous (or, if one prefer, infamous) novel; and Henry Hadley's colorful tone-poem *Ocean.*

Specific art-jazz developments in symphonic form have included George Gershwin's *Rhapsody in Blue;* S. Gardner's *Broadway*, jazz rhapsody; L. Gruenberg's *Daniel Jazz* for small orchestra (Stravinsky's *Ragtime* in its orchestral version, new to this country, might here be mentioned); while the orientally exotic was represented by Henry Eichheim's orchestral *Nocturnal Impressions of Peking* and *Korean Sketch* (chamber orchestra) and *Malay Music.* Among new chamber-music compositions Waldo Warner's *Fairy Suite* for strings; Carl Ruggles' *Angels*, for six trumpets; Domenico Brescia's *American Quintet*, strings and piano, developing South American and negro themes, call for mention. Serge Prokofieff's cerebrally interesting Violin Concerto Op. 19; Edward Collins' Piano Concerto and Leo Ornstein's Tartar-flavored Concerto for piano and orchestra also may be adduced. Orchestral novelties by foreign composers heard include: Edgar Varèse's mathematic, ultra-modern and noisily percussive *Intégrales;* Arthur Bliss' fine *Color Symphony* (Purple, Red, Blue, Green); Béla-Bartók's ultra-modern First Orchestral Suite; Dohnanyi's beautifully written *Festival Overture* and *Ruralia Hungaria* suite (Hung. folk themes); Stravinsky's *Renaud* ballet suite; Caplet's *Epiphanie* (a Magi king fresco for 'cello and orchestra) and Borchard's *Elan*, a symphonic piece expressing "the intoxication of movement." Arthur Honegger's tonal idealization of a railroad mogul, *Pacific 231;* L. Aubert's poem *La Dryade;* the symphonic Overture to Roland-Manuel's *Isabelle et Pantalon;* Manuel De Falla's brilliant, colorfully Spanish *El Amor Brujo* suite, and the clever modernist orchestral "Dances" from Paul Hindemith's opera *Das Nush-*

Nushi, a German *succès de scandale*, also should be cited. New choral works include H. J. Stewart's oratorio *The Hound of Heaven;* Howard Hanson's *The Lament of Beowulf;* Carl Venth's notably fine choral score *Pan in America;* Hermann Hans Wetzler's *Legend of St. Francis*, also a major work; Hugo Kaun's ambitious *Mutter Erde;* Cadman's opera-cantata, *The Sunset Trail* (Denver), a development of Western Indian themes to accompany a tale of the shifting of a tribe to a U. S. reservation; and a "biblical" opera, *The Song of David*, by Ira B. Arnstein, employing Hebraic melodies with jazz inflections in the ballet.

Select References. — Important American books published during the past year include:

DE BEKKER.—*Music and Musicians.* An encyclopædic dictionary, with a good special article on Radio.

MATTFELD, Julius.—*The Folk Music of the Western Hemisphere* (N. Y. Pub. Lib.). The only bibliography (musical, not ethnic) covering the white, red and black peoples of North and South America.

THE THEATRE

BY MAURINE WATKINS
DRAMATIC CRITIC

Play Types.—A year that inherited *Abie's Irish Rose, White Cargo*, and *The Show-Off;* that led off quickly with *Processional, Desire Under the*

Elms, and *They Knew What They Wanted;* that witnessed a remarkable number of revivals of Congreve, Sheridan, Gilbert and Sullivan, Ibsen, and Shaw; that suffered *Aloma of the South Seas, Flesh,* and *The Valley of Content;* that encouraged importations yet sent to an early grave such worthwhile native products as *Close Harmony* and *Lucky Sam McGarver;* that demanded clean, intelligent musical shows and permitted stupid salacity in its drama; that took to its heart *Is Zat So?* and bowed before *The Green Hat.* An interesting and significant year in the drama.

The plays named above are all professional New York productions. Plays are presented increasingly by Little Theatre and other experimental groups throughout the country; every city of size has its commercial theatres for plays on tour and often its own stock company; and Chicago and Los Angeles are professional producing centers, yet according to tradition any consideration of the drama deals with plays that have been seen on Broadway. Perhaps according to reason, for commercial productions elsewhere are, in the main, either triumphantly radiating from New York or hopefully trying to get there. Stamford knows well it is an official taster, and Oshkosh feels satisfaction in "the original New York company."

Growth of the Art Theatre.—Something has happened: Broadway, once a square mile centered about Times Square, now reaches from Cherry Lane to the new home of the Theatre Guild, from the Provincetown Theatre to the Neighborhood Playhouse. Ten years ago a list of notable plays meant a catalogue of the stars under the banners of Belasco, Frohman, *et al.* Even in 1919 the Theatre Guild, then a struggling, penniless band, was the only artistic group that justified its existence professionally. Now, fully one-third of the leading financial successes (if we are to judge by length of run), and at least two-thirds of the artistic triumphs (if we are to believe the critics), belong to the so-called art theatres.

The year marked the tenth anniversary of the Neighborhood Playhouse and the birth of the Stagers and likewise of the Actors' Theatre, which sponsored an unusual program of revivals. The Theatre Guild, once the Cinderella of Washington Square, opened its magnificent building on Fifty-second Street and retained control of two others. The prolific Provincetown group divided: the original theatre was kept for experimental plays; while a second organization, under O'Neill-Jones-Macgowan, devote themselves to a drama less chaotic than *Adam Solitaire,* promptly moving uptown any play that seems a good financial risk. (This has brought cries from the commercial managers: when art makes money is it art? To which the art theatre responds: money is an attendant circumstance, not a purpose.)

The financial success of the art groups in the commercial world is, perhaps, the most significant event in the dramatic history of 1925. The commercial managers, stimulated by this competition, will use more thought in selecting plays and greater care in producing them. Heretofore the art groups have played largely to special audiences who were in full sympathy with their experimental purposes and made generous allowance for shortcomings, greeting with approval whatever was new, irrespective of its merit. Now they are meeting commercial theatres on their own ground, and must face the acid test of dollars and cents. Their more general audience will demand that any deviation from the accepted standard, both in theme and method, be accompanied by superiority. Thus both commercial and art producer may be held to higher standards by the fact that the audience now has a choice. The greatest value, of course, is the effect it will have upon native drama. What so far has been the result?

Native Drama in the Art Theatre.—In the past year, leaving aside the hardy perennials of other seasons and the musical shows and revues, the three plays to which New York gave heartiest approval by box-office returns and critics' verdicts were: *What Price Glory, Desire Under the Elms,* and *They Knew What They*

Wanted. Three plays of American life by American authors.

The first of these, produced by Arthur Hopkins, who is neither "group" nor commercial manager, was written by two army men, Maxwell Anderson and Laurence Stallings, and showed the dirt, the monotony, the petty quarrels and jealousy that spell War. A forbidden subject (war plays had been passé since *Lilac Time*), treated from a daring angle, the play aroused immediate and lasting interest, partly because of its sincere realism and partly, it must be admitted, because of the pungent language which knew not dash nor asterisk.

This was followed shortly by the Provincetown Theatre production of Eugene O'Neill's *Desire Under the Elms,* a New England study; the passion of a stern, puritanical old man for his land, the guilty love between his young wife and his son; the murder of their child with the resultant deaths. Not a pleasant subject, but treated with Greek starkness "to purge the soul of pity and terror by pity and terror."

The third of the significant trio, *They Knew What They Wanted,* produced a few weeks later by the Theatre Guild, was by Sidney Howard, who had formerly been identified with plays in a romantic vein. It told the story of an Italian "picture" bride in California, who turned to a young roustabout on her wedding night instead of the older husband, who was accidentally crippled on the day of the ceremony. Some time later she tells her husband, whom she has come to love, of her experience with the other man: he wants her, so forgives her; she wants love and a home, so she accepts his forgiveness; and the roustabout wants freedom, which is his. They all knew what they wanted and they got it. Well constructed, with discerning characterization, vivid dialogue, and a clear, trenchant philosophy, the play won the Pulitzer prize, offered annually for "that original American play presented in New York which shall best represent the educational value and power of the stage in raising the standards of good morals, good taste, and good manners."—As yet the Committee has not explained upon which count the award was made, but the announcement brought relief to those who feared that Mr. Pulitzer's requirements would limit the prize to such productions as *The Passing of the Third Floor Back* or *The Fool.*

Other Native Plays.—Another Theatre Guild production was the center of controversy for four months or so as it struck a decidedly new note. This was *Processional,* by John Howard Lawson, "a new form in the American theatre, combining the method of the burlesque show with the legitimate form, keeping both to the jazz tempo." It was, incidentally, the only free-form play to attain commercial success, and it was carried over largely by the extraordinary force underlying the entire play.

Such then were the tendencies of the native drama sponsored by the art groups. Stern stuff, of the type known as realistic; unpleasant in theme, sometimes morbid; yet with the power and vitality that mark a living, growing thing.

The following fall (1925) saw a second crop of plays from the most promising of the young dramatists, excepting O'Neill. Anderson and Stallings gave vivid treatment to another war theme (*First Flight*), but the Revolutionary period seemed too remote to arouse great emotion. *Outside Looking In,* a vigorous study of hobo life, by Anderson alone, played with fair success to the special audience upon which the Greenwich Village triumvirate can depend. *Lucky Sam McGarver,* Sidney Howard's study of New York night club life, closed, undeservedly, after a few weeks. George Kaufman, heretofore in collaboration, struck a popular note in the story of *The Butter and Egg Man,* who learned about Broadway first-hand and found it was pay as you enter. George Kelly, of *The Torchbearers* and *The Show-Off,* showed steady advance in technique in *Craig's Wife,* a painstaking characterization of a woman whose meticulous domesticity turned her home into a house—a manless house. Philip Barry, who had gained popular favor earlier with *You and I* and

The Youngest, entered delicate comedy with *In a Garden*.

Native Drama in the Commercial Theatre.—Meanwhile *Is Zat So?*, by James Gleason and Richard Taber, was the crowning favorite, to judge from length of run, of the commercial productions. Peddled about from one manager to another for a period of years, it was finally produced by Earle Boothe with one of the authors (Gleason) in the cast. It is a vigorous comedy of the ring—breaking into society by way of the fist—and the racy diction, human characterization, and punches of various kinds, made it at once a knock-out. This was quickly followed by another Gleason play with George Abbott as co-author: *The Fall Guy*, a dope-peddling story in which the dupe, who thinks he is merely bootlegging, finally turns.

Photographic comedy of middle class life proved generally popular: *White Collars*, an Anne Nichol's offering with millionaire and proletariat; a John Golden production, *Pigs*, by Patterson McNutt; *The Poor Nut*, a play of college life in Ohio, by the Nugents; *The Family Upstairs* (Harry Delf, a vaudeville man), treating the national game of bluff; and *The Sap*, which likewise trailed the success of *The Show-Off*. Vincent Lawrence, who formerly used a lighter touch, joined the group with his golf comedy, *Spring Fever*.

Southern folk drama, quite popular for a few seasons, was evidently not in vogue, and *Ruint*, by Hatcher Hughes, who had won the Pulitzer prize with *Hell-Bent-for-Heaven*, and *The Dunce Boy*, by Lulu Vollmer, who had known distinct success with *Sun-Up*, were given slight encouragement.

The mother theme was given fresh treatment in *Mrs. Partridge Presents*, a worthwhile comedy produced by Guthrie McClintic, with Blanche Bates in the leading rôle and Ruth Gordon, whom the critics found irresistible, as the friend of the family. The contrast in generations was rejuvenated in *Dancing Mothers* (Edgar Selwyn) by a twist which sent mother blithely on her way to live her own life. The triangle play was represented by Gilbert Emery's *Episode*, in which the three characters found an indiscretion just that. The best of the biographical plays was *The Firebrand*, by Edward Mayer, based on the life of Cellini, which enjoyed a long run with Joseph Schildkraut as the hero.

There was the usual assortment of conventional types. Belasco's production of *The Dove* was melodrama at its best. *The Carolinian*, by Sabatini, colorful and crowded with action, was curiously unconvincing. The mystery play hung on in *Spooks* and was burlesqued hilariously in *The Gorilla*. Owen Davis' hundredth play, *Easy Come, Easy Go*, followed the crook formula in farce form, while *Canary Dutch* (Willard Mack) gave the sentimental version.

George M. Cohan, playwright, producer, and actor, returned to his own as all three in *American Born*. The ubiquitous Channing Pollock was present with *The Enemy*, a war tract that seemed quite sane in 1925.

Such is a cross section of native drama in the hands of commercial producers.

Revivals.—It was preëminently a year of revivals. The all-star cast of *The Rivals*, headed by Mrs. Fiske, put Broadway in its place by going on the road first and smashing all box-office records. Walter Hampden, after his triumphal tour in *Cyrano*, settled down to repertory in the Hampden Theatre with Ethel Barrymore as co-star.

The orthodox *Hamlet*, with Hampden-Barrymore, or the Horăce Liveright production of the Dane in modern costumes, with young Helen Chandler, a season's discovery, as Ophelia—New York had its choice. Shakespeare, who has passed all high school and college tests, survived also the sartorial; and left the conviction that "the play's the thing."

Pinero fared comparatively well with Ethel Barrymore as *The Second Mrs. Tanqueray*, but the two Barrie revivals suffered from miscasting. Neither Ruth Chatterton nor Ralph Forbes was suited to *The Little Minister*, and Marilyn Miller was a brittle and sophisticated *Peter Pan*.

Revivals tumbled with rapidity and

seeming ease from the smaller groups. The Neighborhood Players presented *The Little Clay Cart*, a Hindu play one thousand years old, and *The Critic* (Sheridan). The witty, wicked *Way of the World* (Congreve), which fitted in startlingly with certain characteristics of the season, packed the Cherry Lane, and *Love for Love*, beautifully done, was offered by the Provincetown group. They likewise revived the famous *Patience* (Gilbert and Sullivan) with more attention to words than score, yet with stimulating results.

The Ibsen revivals were extraordinarily satisfying. Margaret Wycherley in *Rosmersholm* and Eva Le Gallienne in *The Master Builder* gave memorable performances, and *The Wild Duck*, at the Actors' Theatre, was one of the outstanding productions of the year. Directing honors should go to Dudley Digges for this, for bringing back to the stage Laurette Taylor in the pantomime, *Pierrot the Prodigal*, and for the two interesting presentations of Shaw's *Candida*, which gave opportunity to compare Katharine Cornell, the critics' favorite actress, with Peggy Wood, known heretofore as a singer.

Shaw was represented early in the year by the Theatre Guild production of *Cæsar and Cleopatra*, with Helen Hayes as a flapper siren of the Nile, and in the fall (1925) by *Arms and the Man*, which marked the beginning of the Guild's year of Shaw repertory.

Importations from England.—Excepting Barrie's curtain-raiser, *Shall We Join the Ladies*, Galsworthy was the only one of the more established English playwrights to have a New York première. *Old English*, a detailed portrait of a staunch, human old man, was ably presented by Winthrop Ames, with George Arliss in the title rôle. The smoothness of the production and the actor's well-rounded characterization rather than the play, which lacked the author's usual "spire of meaning," made it a season's success in New York and also on the road.

Also out of England came *The Green Hat*, the stage story of that gallant lady, Iris March, descendant of Camille. It was superbly presented by A. H. Woods with a cast that knew better (Katharine Cornell, Margalo Gilmore, and Leslie Howard). Just around the corner Michael Arlen's other play, *These Charming People*, pictured once more life in Mayfair, with Cyril Maude and Edna Best, accounted the most promising of young English actresses. Mr. Arlen himself in person was accorded throughout his stay in New York the frenzied homage usually reserved for movie stars and prize-fighters.

Another young Englishman, Noel Coward, was also the center of Broadway attention, both for his writing and acting. *The Vortex*, another picture of decadent English life revolving about an unfaithful wife and her drug-taking son—a part created by the author—caused instant sensation. *Hay Fever*, however, his second play, which had gone quite well in London, met with much less success.

Frederick Lonsdale kept the lightly cynical touch that distinguished *Aren't We All?* and *Spring Cleaning* two seasons ago in Ina Claire's vehicle, *The Last of Mrs. Cheney*, in which he made comment on present moral standards in two generations. *Young Woodley*, the story of a schoolboy's affair with the headmaster's wife, was a remarkable first play by another young Englishman just twenty-three years old; banned by the Lord Chamberlain, it found staunch defense in the critics this side of the Atlantic. *The Pelican*, an emotional drama by Tennyson Jesse, followed the pattern for a well-made play of the '90s. Ashley Dukes, the critic, sent over *The Man with a Load of Mischief*, a comedy of Bath in the early nineteenth century.

The younger English group deal with those who dwell in Mayfair rather than with the white-collar class, show knowledge of construction and good "theatre," and have a deftness of touch beyond most American writers, but seem, in general, to have found audiences rather than themselves.

Continental.—The chief French offering in the commercial theatre was a Brieux play (*Accused*), produced by Mr. Belasco, with Sothern as the scrupulous lawyer who is forced with legal precision to face one professional and ethical problem after another. The Alfred Savoir comedy, *The Grand Duchess and the Waiter,* proved merely an entertaining trifle. *The Last Night of Don Juan* (Rostand) was presented at the Greenwich Village Theatre. *The Kiss in a Taxi,* with Arthur Byron, and *Oh, Mama,* with Alice Brady, were perhaps the best of the usual naughty farces.

Stolen Fruit was the Gladys Unger adaptation of Dario Niccodemi's play, in which Ann Harding gave a striking performance as the young school mistress who finds that the illegitimate child she believed to be dead is one of her own pupils.

Hungary furnished the bulk of interesting importations, and Ferenc Molnar was chief of the Hungarians. *The Guardsman,* a sophisticated, clever comedy, was an outstanding Theatre Guild success in the winter of 1924-1925, and *The Glass Slipper,* his Barrie-like story of a Cinderella who spun dreams about a most unprincely man—a Cinderella not quite of this world, played with exquisite feeling by June Walker—was a brilliant opening for their second season. *Carnival,* a vehicle for Elsie Ferguson earlier in the year, pleased the eye and ear but did not satisfy the mind.

Vadja was represented by *The Harem,* produced by Belasco, with able characterization first by Lenore Ulric, then by Vivienne Osborne; and Melchior Lengyel met with success in *Antonia,* which brought Marjorie Rambeau back to Broadway.

Interesting as some of the importations were, none of them had the freshness and vitality of the best native drama, and the conclusion may be drawn that America must look within for her most significant drama.

Musical Shows.—The best of the musical shows reached a high standard. The songs were tuneful but not saccharine, sung in some instances by those who had come via grand opera, proving that a good voice is not necessarily a handicap for a stage career, and the books were, for the most part, intelligent.

Rose-Marie, one of the most popular of the operettas, had an original story of life in the far North, with colorful scenic effects and carefully balanced dancing. Three of the most successful had books based on romantic stories that had long been favorites: *The Student Prince,* a delightful musical version of *Old Heidelberg,* with Ilse Marvenga and Howard Marsh; *The Vagabond King,* based on the Francis Villon story, *If I Were King;* and *Princess Flavia,* which retold with music *The Prisoner of Zenda.*

Musical comedy also kept to stories that had proved their popularity: *Captain Jinks,* a dancing version of the singer's career; *The City Chap,* based on *The Fortune Hunter;* and *No, No, Nanette,* from the comedy, *My Lady Friends.* This last was a professional anomaly, the first company (with Louise Groody) played for over a year in Chicago and others elsewhere before it was brought into New York.

Big Boy, Louie the 14th, and *Sunny,* with Al Jolson, Leon Errol, and Marilyn Miller respectively, found favor, and *Lady, Be Good* was made a high point of the season by the delightful dancing of the two Astaires.

New editions of the Follies and the Music Box Revue were added to a goodly number of scandals and vanities. The art theatres ventured even here, the juniors of the Theatre Guild presenting a zestful show in *Garrick Gaieties,* and the Neighborhood Playhouse offering clever burlesque on the season's successes in *The Grand Street Follies.*

Immorality and Censorship.—Conditions back of the footlights, generally accepted as concerning only the participants, have long been a subject for reformers, but the phase affecting the audience—the character of the plays—has now become their task. At all times on the boards appear productions, both of musical and dramatic nature, which would offend certain persons; most of the time some plays are on which would prove distasteful, morally, to many; and 1925 saw some which incited to rebellion even the actors, of an indecency admitted by the producer himself.

Who is responsible for such a condition? The public blames the producer, and he tosses the ball back by declaring that he gives them only what they demand. The Puritan considers such indecency an integral part of the drama; and the non-city man, smug in the knowledge that such plays cannot come to his town, attributes it to the inherent wickedness of the New Yorker. He, in turn, charges the out-of-town visitor, who flocks to shows in New York that he would never attend at home. And he adds as explanations the heterogeneity of the city, the preponderance of foreigners with generally lower standards of morality, and the by and large characteristics of theatrical producers.

Whatever the reason, early 1925 saw a goodly assortment of cardinal sins, treated from various angles. Possibly certain managers were inspired by the financial success of the art groups and decided to follow the unpleasantness of their themes; but they missed the method of treatment, substituted salacity for sincerity, and merely plunged into a season of pornographic photography.

One play was called to the attention of the police, then another. The District Attorney stepped in, and the pulpit and press, in a righteous desire to clean up the stage, turned on full power of tongue and pen, denouncing by name both plays and producers.

Then New York was treated to a page from Gilbert and Sullivan. One manager offered to close his show, virtuously asserting that he had produced it merely to waken the public to the condition of things in Denmark. Another halted at withdrawal but suggested deletion of offensive lines; whereupon the first withdrew his offer to close. And while Attorney and Commissioner reflected and press expounded and reformers wired in advice, the productions under fire did business to capacity houses, for the public at once flocked to see what it was all about. One play, practically scheduled to close because of empty seats, ran on for several weeks on such publicity.

Clearly the existing condition whereby the manager produced his play and ran the risk of arrest if it was indecent was unsatisfactory. Was there a solution in censorship? The word aroused a whirlwind of protest.

"Censorship will not hurt the second-rater!" said Laurence Langner. "He can adapt himself to it. But it can hamper and even destroy the man of genius, whose imagination must range untrammelled in any field he chooses, if we are to have the fruits of his talents. An O'Neill writing plays to suit an American censor is unthinkable; a Sidney Howard deciding beforehand whether some political appointee will object to his writing *They Knew What They Wanted* would be a calamity. A censorship in the American theatre would emasculate our authors at a time, the first in our history, when their vigor and artistry is winning international recognition." (*Theatre Guild Bulletin*, November, 1925.) To which the conservatives respond: It is true England has no Avery Hopwood, but there are Masefield, Shaw, Galsworthy, Drinkwater, Barrie.

Play Jury.—More plays came to the attention of the District Attorney—some dozen all told—and finally, after various proposals, the Play Jury plan was adopted. A panel of twelve, drawn from one hundred worthy and judicious citizens listed with the Police Commissioner, were to attend separately each offending play, and their verdict—cut, revise, or withdraw—was to be final.

The play selected for the first visitation was *Desire Under the Elms*. Again a storm of protest from those who felt to question O'Neill was blasphemy. Telegrams that made excellent advertising copy poured in from all parts of the country: if evolution had its Scopes, the drama had O'Neill.

The jury gave *Desire* a clean bill, suggested revision in one or two other plays, and gradually faded out with every one happy. The Puritan had proved there was something wrong with the stage, the advocate of freedom had sidestepped censorship, the forces of Law and Justice had demonstrated that they could handle the situation, and the managers had doubled their profits.

But certain questions lingered in the public mind:—What determines the morality of a play? The subject matter? Why is the Bible privileged? How long must a man be dead to gain the freedom of the Greeks and Shakespeare? Is it treatment? Or the effect on the audience? And who shall judge that effect beyond the man himself?

Disturbing questions, not answered in 1925.

MOVING PICTURES

By Maurine Watkins
Motion Picture Critic

Year's Trend. — Moving pictures, which have risen in the course of a quarter century to fourth place among American industries, enjoyed a year of prosperity in common with the rest of the country. No more pictures were produced than usual, but large returns were realized, due in part to increased public support, which the radio, contrary to the fears of a year ago, did not diminish, and in part to the decline of the stupendous spectacle picture which relied for appeal primarily on its lavish expenditure and impressive numbers. Laying aside circus tactics also furthered the development of moving pictures as an art. Bereft of his gilded trappings the producer was forced to interest his public by an appeal to the mind rather than to the eye alone, and consequently the offerings of 1925 were of a higher standard than heretofore.

Subjects.—A glance at the titles of the year shows that some of the old type favorites remain: there were a few Westerns, such as will always attract, so long as small boys and swift riders exist; two or three of the siren pictures that made movies infamous a dozen years ago but seem ludicrous anachronisms to-day; and several dying gasps of the flaming youth movement. But the more ambitious productions essayed new fields; not necessarily different kinds of stories, but in a different mood. The slapstick comedy gave way to a humor that was more subtle and often intellectual, and satire and fantasy, a combination that would have been impossible three or four years ago, were successfully blended.

Successfully, that is, from the artistic standpoint, but not from that of the box-office; for the producer found that when he left his special, sophisticated audience of New York and the larger cities, these pioneers in artistry fell flat. His general public did not care for delicacy, nor sincerity if accompanied by a grim story, and satire which left them wondering what it was all about. In appreciation the public has not kept pace thus far, with the producer.

Methods. — No great physical strides were made, no striking innovations in mechanical devices, and the stories in general followed the conventional form. But as the director now gets his effects by a skillful selection of detail rather than by massing a hundred Numidian lions, so the actor is using restraint and suggestion instead of gymnastics and facial contortion. Motion pictures seem to have grown up physically at least, and both director and actor are bending all efforts to develop mentally, to fill out the hollow places in this enormous structure, and to smooth off the rough corners that necessarily accompanied such rapid growth.

Shifting Interest. — Back in the days when the movies were young, films were known by the companies that sold them: an Essanay, a Vitagraph, a Universal. Then as certain personalities among the actors stood out consistently, the public began to demand their names, and soon there developed the star system, which choked the growth of the art for several years. This system will probably never die out, for certain individuals will always possess more magnetism and appeal than others, but it is gradually giving way to the sovereignty of the director.

A study of the half dozen best and worst films of the year shows that in most cases the director was responsible. Stories that seemingly held promise were lost in the filming, capable actors met surprising failures; while a talented director, with the aid of an adequate cast, would whip a mediocre, trivial story into a thing of delight. Many of the companies have become so large that they seem mere distributing centers; certain stars are so eager to duplicate yesterday's success that their names are merely trademarks for those who want standardized amusement of a given brand; but the announcement of a production by any one of four or five directors means a picture that is worth watching, an event that may be significant in the onward march of the motion picture.

Cool Receptions.—*Greed*, the Eric von Stroheim production of Frank Norris' novel *McTeague* was the most ambitious undertaking of the year and a revelation of what the movies can do when they will. A story told without a wasted stroke, penetrating characterization by Zasu Pitts, bitter, relentless, inevitable—the public would have none of it. They were also bored by *The Last Laugh*, an Ufa (German) production, which stood unique among the year's films for simplicity and pathos. Emil Jennings gave a remarkable portrayal of the old doorman who loses his grand, liveried position, steals his uniform and continues to wear it home so that his family may not know his disgrace; and finally, by chance, comes into a fortune that enables him to return to the hotel and enjoy the last laugh. The story was told entirely in pantomine without the aid (or hindrance) of subtitles—a real moving picture. Neither did the public (outside of New York) care for *Beggar on Horseback*, that curious mixture of satire and fantasy by Marc Connelly and George Kaufman, which was brought to the screen by James Cruze.

Notable Successes.—On one picture, however, public and critics were agreed: the adaptation of Barrie's *Peter Pan*, directed by Herbert Brenon. Faithful to the author's intent it caught the magic of Never-Never land and sustained the mood throughout—a triumph of wistful beauty. A satisfying production in itself, it was also important because it discovered three unknown actresses who quickly took their places in the film world: Betty Bronson, whose eager spirit of elfin youth made her an ideal Boy Who Never Grew Up: Mary Brian, the gentle Wendy, who became the most natural girl on the screen; and lovely Esther Ralston, who played Mrs. Darling.

Another worthwhile picture that found public favor was von Stroheim's second offering of the season, *The Merry Widow*, a brilliant version of the light opera, which showed wit and intelligence, and revealed Mae Murray as something more than a clever dancer and John Gilbert as the most popular of leading men.

The Vanishing American, a Zane Grey story of an Indian's love for a white girl, was intended to repeat the success of *The Covered Wagon*, but lacked the epic quality that distinguished the earlier picture. *The Wanderer*, following the religious tide of *The Ten Commandments* of the previous year, was a lavishly beautiful re-telling of the prodigal son, directed by Raoul Walsh, with a season's find, Greta Nissen, as Tisha the siren; and William Collier, Jr., as a lovable adolescent black sheep. *Siegfried*, a Ufa production, was a spectacularly impressive but dull version of the Niebelungen legend.

The Phantom of the Opera was hailed long in advance as Lon Chaney's masterpiece, but the famous make-up hid him too completely, and his artistry in pantomine was shown more clearly in *The Unholy Three*, a crook melodrama with a midget, a strong-man, and a ventriloquist—the thriller of the year. The heart picture of 1925 was *Stella Dallas*, a story of mother love and sacrifice, kept from over-sentimentality by careful directing by Henry King and excellent acting by Bella Bennett.

With the Actors.—The established stars for the most part repeated themselves in the type of play that had brought them fame and wealth. Mary Pickford returned to curls and childish pranks in *Little Annie Rooney;* and Douglas Fairbanks continued his dashing, breath-taking career in *Don Q*, son of Zorro. Charlie Chaplin became again a lone, gay, pathetic little figure with the hat, cane, mustache, and walk that mean Chaplin, in *The Gold Rush*, an uneven production with slapstick comedy and genuine pathos. Jackie Coogan, grown a little taller and a bit self-conscious, returned to his cap and baggy trousers in *The Rag Man* and *Old Clothes*. Lillian Gish was once more wistful and lovely in *Romola*, a picture historically authentic but which was slow in movement and held interest primarily by the comedy work of Dorothy Gish. Valentino came back as *The Eagle*, a lone Cossack bandit who is loved by a queen, but did not quite recapture the fire of *The Four Horsemen of the Apocalypse.* Norma Talmadge held her title as an emotional and romantic actress in *Graustark.*

Harold Lloyd produced another comedy (*The Freshman*), which witnessed college life and the football field through his spectacles; and Thomas Meighan went steadily on his way in George Ade stories. Pola Negri continued her vain search for a script that suits both her temperament and the taste of Mr. Will Hays, Movie Censor; and Nazimova curbed her power, to good advantage, in a subdued portrayal of the Portuguese mother in the Cape Cod story, *My Son.* Corinne Griffith still gave her beauty to films that demanded slight effort; Bebe Daniels gathered popularity in such trifles as *The Manicure Girl;* and Mary Astor and Mary Philbin continued to be the loveliest of screen actresses.

Gloria Swanson, who advanced at least in publicity, took a fling at history in *Madame Sans Gêne;* tried double emotional rôles in *The Coast of Folly;* and then returned to the characteristic comedy of her earlier days in *Stage Struck.* Colleen Moore, after an ambitious but not wholly satisfying attempt as the mother in *So Big* and a Cinderella part in *The Desert Flower,* gave a sparkling performance in *Sally,* sharing honors with Leon Errol, who had created on the stage the part of the dancing waiter. Marion Davies, proving the efficacy of hard work, satisfied a large public and some of the critics with her comedy work in *Zander the Great,* and then returned to a picture of New York life in *Lights of Old Broadway.* Norma Shearer demonstrated great versatility and took first place among the younger actresses.

Betty Bronson was undoubtedly the find of the year; she passed quickly from Peter Pan to the rollicking Bret Harte heroine of *The Golden Princess,* then to a modern rôle in *Are Parents People?* to a sweet costume part in *Not So Long Ago,* and back to whimsicality in another Barrie film, *A Kiss for Cinderella.* Vilma Banky, a lovely blonde from Budapest, was the second newcomer of great promise; she showed strong emotional possibilities and haunting grace in *The Dark Angel,* and was later a foil for Valentino in *The Eagle.* Greta Nissen, also straight from Europe, was the ballet dancer in *Beggar on Horseback* and the enchanting siren of *The Wanderer.*

Among the men Adolphe Menjou stood out as a sophisticated, dependable actor, with perfected technique, in adult comedy. Percy Marmont continued his sacrificing career, partly because he plays intellectual and spiritual characters so well, and partly because there are so few screen actors who could do such parts at all. John Gilbert made remarkable advance in both skill and popularity, and Ronald Colman also became a promising leading man. Richard Dix gave a splendid performance in *The Vanishing American,* and Richard Barthelmess, known heretofore in serious and romantic rôles, broadened his range by a delightful comedy, *Shore Leave.* Buster Keaton added *Go West* to his list of solemn comedy portrayals, sharing honors with a cow; and Raymond Griffith, with *Paths to Paradise* and *A Regular Fellow,* showed he had joined Chaplin and Lloyd as a distinctive comedian. Reginald Denny had a swift farce in *I'll Show You the Town,* and Syd Chaplin as *The Man on the Box* and *Charley's Aunt* became something more than Charlie's brother.

With the Directors.—Foreign directors lead in both strength and sophistication, but the Americans are gaining rapidly. The power of *Greed* (von Stroheim), *Siege,* a stern New England portrait by Sven Gade, and *The Tower of Lies* (Seastrom), and the intelligence and appreciation back of *The Merry Widow* (von Stroheim) and *Kiss Me Again,* a trifle tossed off by Ernst Lubitsch, were not paralleled. But Monta Bell brought a fresh, independent touch to *Pretty*

Ladies; King Vidor showed feeling for satire in *Proud Flesh;* and Tod Browning, originality of method in *The Unholy Three.*

Peter Pan and *A Kiss for Cinderella* revealed Herbert Brenon at his best. James Cruze showed the greatest versatility; fantasy and satire in *Beggar on Horseback;* quiet humor in *Marry Me,* best of the small-town comedies; and the sweeping action associated with his name in *The Pony Express,* a story of Lincoln's time. Mal St. Clair, twenty-eight years old, gave brilliant promise with the production of *The Trouble with Wives* and lived up to it with *The Grand Duchess and the Waiter. The Dark Angel* owed its background of artistry and beauty to George Fitzmaurice.

D. W. Griffith, dean of directors, gave the public a sincere, simple story with German setting in *Isn't Life Wonderful?* and when they did not care for it, turned to carefully planned comedy effects with *Sally of the Sawdust.* Clarence Brown turned out an extraordinary character study in *The Goose Woman;* Allan Dwan, long the guider of Gloria Swanson's fortunes, did excellent work with *Night Life of New York;* and Rupert Julian made *The Phantom of the Opera* an interesting study of the weird.

Altogether it was a promising year: directors put aside lazy methods and brought to the films sincerity, imagination, and an intelligence that means much for the future.

With the Authors.—Original writing, if such there be in films, has in no way kept pace with acting, and directing. Some of the best captions of the year were lines lifted from the stage versions, and in certain cases fairly good films were ruined by the stereotyped, sentimental subtitles that have been in stock for ten years. Stories written directly for the screen were usually mediocre; sometimes they were the product of regular scenario writers, but more often the work of a novelist or playwright lured to Hollywood by blare of trumpets and clink of coin. Joseph Hergesheimer, from whom much might have been expected, turned out an unimportant story in *Flower of the Night* for Pola Negri, and Michael Arlen will make his contribution to the lady in *Crossroads of the World,* for the title of which he received fifty thousand dollars. A notable exception was *The Big Parade,* a story of the Great War written by Laurence Stallings.

Certain screen versions of stage successes were admirable: *The Merry Widow, Sally, The Dark Angel, Sun-Up, Shore Leave, Charley's Aunt;* but others were faint shadows: *The Boomerang, The Circle, Grounds for Divorce, Déclassée, East of Suez.* Sometimes the directors were responsible, but at others the Censor limited them in such a way as to make the story pointless.

The development of moving pictures is shown in the type of novel chosen for adaptation. The historical (*Romola*) and colorful (*Graustark*) still have their place, but the quiet and psychological were also attempted. *The Little French Girl,* Anne Sedgewick's study, of French and English morals; *So Big* (Edna Ferber); *Lord Jim* (Joseph Conrad), which unfortunately was shifted into mere melodrama; *Faint Perfume,* which lost entirely the flavor of Zona Gale's novel; *The Lost Lady* (Willa Cather's painstaking study); *Proud Flesh, The Homemaker, Wife of the Centaur*—none of them wholly successful, some very bad indeed; but they show the direction in which the movies are going, and it is significant that the failures were due for the most part to execution—the reach exceeded the grasp—and not to deliberate distortion of the story.

Interesting Productions.—Out of the multitude of films, the following are especially noteworthy:

The Lost World: Conan Doyle's tribute to the brontosaurus, pterodactyl, and allosaurus.

Grass: dealing with the migration of the lost tribe of Persia.

Her Night of Romance: which tied Connie Talmadge with Dorothy Gish for first honors in comedy.

The Street of Forgotten Men: an interesting story of a fake crook, admirably portrayed by Percy Marmont, directed by Herbert Benon.

Are Parents People? another view of Betty Bronson, this time as the little child who leads them.

Old Home Week: Thomas Meighan himself in a George Ade story.

Pretty Ladies: a clever portrayal of life in the Follies.

The Homemaker: Alice Joyce and Clive Brooks in a sincere study of marriage and economics.

The Goose Woman: a weird study of a prima donna with an especially remarkable performance by Louise Dresser.

A Kiss in the Dark: sophisticated satire with Adolphe Menjou.

Cyrano de Bergerac: admirably done by a French company with Pierre Magnier.

The Wizard of Oz: a delightful picture for children.

Friendly Enemies: Weber and Fields with tears and smiles.

Hell's Highroad: Cecil B. DeMille's first comedy production as an independent.

I'll Show You the Town: a lively farce based on Elmer Davis' novel.

Drusilla with a Million: a tearful story with Mary Carr.

The Last Edition: Emory Johnson popularizes the newspaper.

DIVISION XXXIX
ACADEMIC EDUCATION

MODERN METHODS IN EDUCATION

By Robert G. Jones

Superintendent of Schools, Cleveland

Society and Education.—We have in this year of our Lord 1925 rubbed our eyes as never before in recent years in America and said "No matter what comfort we have enjoyed in espousing democracy, we have purchased this comfort at a sacrifice—the sacrifice of indulging ourselves in the belief that all are born free and equal mentally, and that all can, therefore, aspire to the maximum powers to achieve."

We have been committed to mass education in the face of a vast peasant immigration, in the face of biology, in the face of history, in the face of experience. With a dilution of advanced, abstract education designed for select minds of worth we have endeavored to educate a mass less endowed with power to achieve and with so much less of the hereditary background so essential to character.

We have advanced in the differentiation of abilities on the one point scale of mental strength. Dr. Bird T. Baldwin is just now writing a report on a five point scale of appraisal, to wit: intellect, social worth, physical worth, achievement and moral worth. Selection and classification of qualities which contribute to successful living are passing from the rule of thumb to the scientific stage less rapidly than the differentiation of abilities has advanced. This year has developed more anxiety for a curriculum to fit these differentiated abilities than ever heretofore, but textbooks are rarely available for either the extreme lower or higher levels of learning power.

The public balks at a preparatory or private school because it wants its children to grow up in the hurly-burly of general school life, in contrast to a sequestered group of boys or girls which may be gathered into some quiet school nook even under capable teachers. They do not quite like the composite of the groups—some sent there to get the atmosphere of better scholarship; others there to get them out of home influences; still others for disciplinary reasons. Boards of Education are trying to reduce costs and at the same time maintain secondary education on an even keel, but it is a hard job to find, keep and develop in high schools, men of the kind one would have, at present salaries. There are not enough good ones to go around. In secondary education there seems no great advance this year. We have sought, through organization, new textbooks, devices, expedients, athletics and fine buildings to make education, but these are neither the warp nor the woof of it. It requires men and women of ripe scholarship to command the respect of youth fourteen to eighteen years of age.

Compulsory Education.—The compulsory education laws have in some states moved up the age limit to eighteen with a saving clause "at sixteen if employed." That this is a movement of doubtful value is indicated by ability tests. The presumption is that vocational or trade schools will provide for this over-age group, but the trade schools are not yet developed, and communities are not in funds to increase expenditures for this type of education, particularly for capital outlay.

Junior High Schools.—Junior High Schools are increasing in tremendous numbers—faster than teachers are trained to manage them, and surely faster than managers are capable of understanding them and projecting work for youth of this age. The teaching staff is composed of former seventh and eighth grade teachers, many of whom have to their credit but two years of training beyond the high school, supplemented by considerable experience of more or less worth, depending upon their environment and direction.

When poor teaching and meagre preparation have failed to carry inspiration holding quality in the seventh, eighth and ninth years, the curriculum has been "jazzed up" with concrete types of instruction for so-called exploratory purposes. This is of questionable value, for the good reason that youth 12, 13 and 14 years of age rarely manifest deep interest in what their future work will be. In short, they are too young to decide such questions. Boys at this age are all quite interested in mechanical affairs and might easily be diagnosed early for engineering, when maturity might quite contradict the decision.

Education of Special Classes.—Differentiation on the score of abilities has in the main taken the form of provision for special classes. Since the states have been slow to accommodate all mental defectives—that is the group having a mentality of about I. Q. 70 or below—communities have sorted out many of these into special classes offering at least 50 per cent. of handwork. The advantage is twofold; it relieves the regular classes and offers work better suited to the low mentalities.

Some provision is also being made for classes of gifted children. The discoveries are interesting and stimulating. It is demonstrated that these pupils are not far advanced beyond other children at the outset, and usually they have not developed studious habits because they have never had competition. It is equally amazing to observe what a volume of work these pupils can accomplish when put upon their "mettle."

Delinquents.—Some advancement is being made in treating delinquents, boys especially. No doubt the desire to prevent crime as much as the desire to render justice to the boys, has stimulated the care for this group on the part of the community. Prevocational trade studies and character guidance through personal contact, music, play and applied arts have contributed much to the improvement of such groups.

The groups of non-conformist girls about sixteen years of age present an equally engaging problem, but curricular material suitable for such groups is all too limited at present, nor have teachers been trained for this branch of service. Coöperative relations with industrial and commercial concerns are, however, under way since considerable material is now available on job analysis with a view to providing work suitable for girls.

Educational Theory.—Educational theorists have been pointing out for many years that society is interested in learning how children behave in their own groups, among their fellows and in situations which natural association with their elders thrust upon them, and later how they will act as men among men. They have indicated that present practice in the schools might be interpreted to mean that school administrators, and even some teachers, are interested primarily in classroom behavior, as leading to the highly specialized behavior known as "passing examinations." They have also delved into what pupils ought to learn and how they ought to learn it. In the first inquiry, they all agree with society; in the second, they have rediscovered the importance of interest as an element in producing effort.

As a result, we are busy rewriting our courses of study in terms of pupil interests and desired changes in their attitudes, habits, knowledges, skills and character. In the elementary field ten committees, each assigned to a special subject, are working upon a revision of the courses in these subjects. In the junior and senior high school field the reorganization of the social studies has been much advanced.

Another new theory is that many childish experiences, some unique but many quite commonplace, affect seriously the attitude of children toward desirable habits and facilitate or hinder their learning. To solve the problems created by this situation just now recognized by scientists in education, it would seem that the educational psychologist must move over and invite to a seat by his side the educational psychiatrist, and that both must be aided by medical and social workers. The children in one elementary school in Cleveland are now undergoing a thorough examination upon the more subtle behavior problems with a view to detection of evils and correction. Careful scientific studies of psychiatric service are under way at Teachers' College, Columbia University, and at the University of Minnesota.

Trade Education.—Trade extension education is sharing more attention as funds become available and as adjustments are made between employers and the unions. Such adjustments are rather easily made at present, since the building trades are short of skilled workmen. The employers pay wages for the full day and send the employee to the trade school for one day each two weeks. Successful classes are being conducted in bricklaying, plumbing, interior decorating, house painting, carpentry, electricity, automobile mechanics and in one instance classes have been organized for telegraph messenger boys. Some trade schools are under way for general mechanics, and no doubt the number will be steadily increased if general prosperity continues and the demand for skilled labor does not slacken. The unions may leave apprenticeship instruction to the public schools in a larger measure if the schools refrain from discussion of labor problems, and stick to the subject of trade education and such supplementary academic training as contributes to the efficiency and social worth of the student.

Adult education is decidedly on the upgrade, not only in trade subjects, but in the various fields of general culture, especially in directed reading, through courses offered by the public libraries.

The shorter work day, increased standards of efficiency in commerce and industry, higher living costs, desire for the next stage of social recognition, and a desire for knowledge for personal satisfaction, all contribute to cause this demand for adult education. The question before us is: How far shall free public education go? There is some protest against advancing tax rates, but in turn one is forced to consider whether education does not increase property values and production sufficiently to warrant increased school tax assessments.

In any event, if educational opportunities are sufficiently desired the public school building will, no doubt, be opened on a tuition basis. The Y.M.C.A.'s and the colleges will continue their schools on a tuition basis, and what the public wants it will purchase either directly or indirectly. Probably no more striking evidence is at hand of adults' desire for education than the enrollment in private schools and in correspondence schools. The important fact remains—that the demand is present.

Teachers' Training.—The tendency to change the title "normal school" to "school of education" may, at first thought, seem pretentious which, no doubt, it is in many instances; but the change in title also connotes a change in the length of courses from to three or four years. While this is true of larger urban centers, it will be observed that in rural districts the advent of centralized schools has brought in its wake higher standards. The expansion of training for professional school work is not as yet keeping pace with or meeting the demand for suitable teachers. This is due, in part, to prosperity in trades which offer some advantages to talent that a circumscribed standard school schedule will not permit. The day of the merit schedule for schools is not here, but some plan for greater flexibility must necessarily be offered soon. Altogether the outlook for the year is the best in history.

The Public's Interest in Public Education.—The parent-teacher organizations, now country-wide, are increasing in numbers and interest. One should make haste to add that the attitude of this group is constructive and the organizations are inclined to study the ways and means of school work and contribute to its success.

Less adverse criticism is in evidence than ever existed before. There is no more effective agency than the parent-teachers' organization to promote the welfare of public schools. Its value has been tested in the selection of substantial members for boards of education and in support of tax and bond measures in the general elections. This represents more than a temporary local assistance; it augurs well for our democracy and we may express the hope that the keen interest in educational affairs will spread to the betterment of municipal management.

IMMIGRANT EDUCATION IN THE UNITED STATES

By Helen Hart

Head Worker, East Side Settlement House, New York

Transfer of Interest.—The year 1925 marks a definite transition in the history of the so-called Americanization movement, at least so far as its educational aspect is concerned. Immigrant education has finally ceased to be considered patriotic propaganda and has taken its place as a part of a larger movement for "Adult Education." In the National Education Association the Department of Immigrant Education, which three years before had taken over most of the functions of the Inter-State Council on Immigrant Education, was definitely reorganized at the Indianapolis meeting in June as the Department of Adult Education, and its program expanded to include the anti-illiteracy campaigns being conducted in many states, as well as the movement for "Workers' Education for Leisure."

In the Federal Bureau of Education, which during the war and for a short time thereafter had a "Director of Americanization," the position of "Specialist in Adult Education" was created in May. Several state departments of immigrant education have been reorganized to take over the responsibility for the teaching of native-born illiterates; and in states where the work is being newly organized it is often made a part of the department handling vocational education as well.

This tendency on the part of "Americanization" to lose its separate identity is due in part to a reaction from the spirit of wartime propaganda unwisely exploited by a few leaders in the movement, and in part to changing conditions brought about by the restriction of immigration. Far-sighted leaders in the movement have realized that in order to protect it from the rising tide of suspicion and intolerance now evident in many parts of the country toward immigrant groups it should be made a part of a larger educational program; they are looking forward, too, to the time when, under restricted immigration laws, most of the foreign-born residents in their states will rapidly acquire a working knowledge of English and will be ready to join with their native-born neighbors in the study of cultural and vocational subjects. In states like California, Connecticut, Delaware, Massachusetts, Pennsylvania and others whch have retained the leadership of educators who have made out-standing contributions to this highly specialized field, the tendency to relate immigrant education to the larger field of adult education can mean nothing but gain. Where, however, as has happened in many states, such classes are placed under the general supervision of schoolmen with no adequate conception of the special problems of immigrant education or of the uniquely efficient methods that have been developed of recent years to deal with them, a reversion to the old conditions of apathy on the part of the schools and discouragement on the part of the immigrant pupils is already evident.

Education for Citizenship.—Another general tendency, caused largely by the new immigration law, which gives preference to the relatives of naturalized citizens, is the increased emphasis on education for citizenship and the increased demand for such education, especially among immigrant women. The naturalization of women has also been stimulated, unfortunately, by widows' pension laws. Educational agencies which are eager to give their pupils a genuine preparation for citizenship find it extremely difficult to give adequate training to women who are already handicapped by the necessity of earning for their children during the day and caring for them in the evening.

Differentiation of Treatment.—A third development pointed out by all the leaders in this field, is the need of adapting courses of study to new types of immigrants now entering the country, particularly to the middle class German with high-school or university education, who is capable of extremely rapid advancement, given efficient language teaching, and who cannot begin to make his skilled contribution to America until he has this. It has been found that where special instruction could be given to these pupils, apart from the peasant groups whose early education has been very limited, great gains have resulted.

National Developments.—In May, 1925, Dr. L. E. Alderman, of Oregon, was appointed "Specialist in Adult Education" in the Federal Bureau of Education. Although the field covered by this office is large, there is a general gratification at the renewal of federal leadership in immigrant education and a hope that it will make possible a better exchange of experience between the states. Shortly before Dr. Alderman's appointment, Mr. Charles W. Herlihy, Director of Alien Education for the State of Massachusetts, prepared a report on state activities, at the request of the Commissioner of Education. It is understood that this report will shortly be available in printed form.

The educational activities of the Naturalization Bureau, in the Department of Labor, have been somewhat curtailed since the beginning of the year, but the Bureau continues to issue copies of its textbooks in English and Citizenship to aliens who have declared their intention of becoming citizens. The revised editions of these textbooks have been prepared by experts and are exceedingly useful.

Present Status.—Because of the merging of Americanization work with other forms of adult education it is impossible to give a clear picture of the progress now being made in the education of non-English-speaking residents as apart from native illiterates. The combined figures, however, are exceedingly interesting. The 1920 census shows that of about thirteen and a half million foreign-born persons in the United States, about one and a half million could not speak the English language; about one million eight hundred thousand were illiterate. In addition to these foreign-born illiterates were over three million native illiterates. Answers to Mr. Herlihy's questionnaire and other official figures and estimates compiled more recently indicate that between 325,000 and 350,000 are now enrolled in classes out of perhaps five and a half million who are illiterate or non-English-speaking, or both. In nine states having a non-English-speaking population of from 10,000 to 172,000 (Colorado, Illinois, Indiana, Kansas, Michigan, Missouri, New Jersey, New Mexico and West Virginia) there appears to be no state leadership in immigrant education and no figures as to enrollment in local classes are available.

Statistics.—Following is a summary of reports from 18 other states, in which the problem of non-English-speaking and illiterate foreign-born residents is important and is receiving definite attention from state educational authorities. It is interesting to note how uneven is the relation between the seriousness of the problem and the work being done, even in these states.

	Non-English-Speaking	Foreign-Born Illiterates	Native Illiterates	Communities Having Adult Classes	Pupils Enrolled
Arizona	36,352	19,291	3,571	5	160
California	69,570	69,768	10,326	103	39,908
Connecticut	38,068	63,131	4,005	42	11,481
Delaware	2,733	3,373	7,127	15	1,504
District of Columbia	779	1,728	8,693	...	971
Maine	10,333	11,604	8,460	18	2,068
Massachusetts	96,426	135,720	10,345	104	30,000
Minnesota	28,311	26,242	6,196	40	10,679
New Hampshire	11,339	13,746	2,006	17	3,060
New York	290,200	389,603	33,438	140	102,384
North Dakota	10,189	7,238	1,323	22	2,283
Ohio	81,161	84,387	46,441	50	33,000
Pennsylvania	162,240	258,812	53,515	65	18,562
Rhode Island	21,620	28,169	3,094	17	2,685
Utah	2,303	3,504	984	4	1,123
Washington	7,796	11,630	2,624	16	3,777
Wisconsin	44,481	38,359	10,631	47	2,806
Wyoming	2,003	2,233	487	34	912

State and City Programs.—There are nine or more states in which a definite program of immigrant education has been developed steadily under expert leadership for several years. Almost all the important gains made in the organization and technique of immigrant education are to be traced to these state programs, rather than to city school systems in which supervisors seldom have the freedom to develop new methods. Most of these state programs are based upon the principle of state aid to local districts in the maintenance of classes. The simplest form of state aid and that most commonly found is the "50-50 plan," under which the state agrees to reimburse local communities each year for one-half the cost of instruction to adult aliens in English and citizenship. Under this plan in Massachusetts the number of immigrants in such classes increased from three thousand in 1919 to thirty-two thousand in 1924; 40 communities had full-time supervisors in 1925 and 50 had part-time supervisors. In Maine, the state pays two-thirds the cost of such classes. In New York, state reimbursement to local communities consists simply in the payment of one-half of teachers' salaries up to $1,000; under this law over 100 communities have appointed supervisors or teachers in charge of the work. In California, state reimbursement to local communities is based on attendance in English and citizenship classes, a bonus of $2,700 being granted by the state and county to each local district on its first thirty units of average attendance. This makes possible in many country communities the employment of full-time supervisors, who make union high-schools their headquarters and establish classes in neighboring district schools. In Ohio, which has no plan of state aid, a large number of cities have tried the experiment of charging the pupils for part or all of the cost of instruction; Cleveland charged each pupil a $2 fee for the course of 36 sessions, thus raising $14,000 in addition to the $65,000 appropriated by the School board. The Citizens Bureau of Cleveland, a private agency doing exceptionally good work in naturalization education and personal service to immigrants, reports that during 1924 tuition fees in its classes showed a clear profit of more than $2,700 which was applied on other services rendered, but adds that this profit involved intolerable crowding in classes, and that a change in policy in the direction of making these classes only self-supporting has been adopted in 1925. In the District of Columbia, the "Americanization School Association," made up largely of graduates of the schools, raised enough money to pay for a summer session. In a few states, in most of which the native illiteracy problem overshadows the need for immigrant education, state supervisors of adult classes are still working toward getting them financed by private individuals of means, or by patriotic societies.

The importance of adapting schedules and meeting places to the special needs of immigrant pupils has been increasingly recognized by progressive workers. The District of Columbia, for example, has day classes for unemployed men, night-workers and women, with kindergarten care for small children while their mothers study.

Delaware has day classes also and home-classes for mothers and will establish a class anywhere where ten or more immigrants wish to learn. This is in marked contrast to New York City, which still insists upon a minimum of thirty pupils to a class, in spite of renewed protests by civic agencies.

Work of Private Agencies.—In states with adequate programs of immigrant education the tendency is more and more for private agencies to work for the increased efficiency of public classes, rather than to duplicate them. American Legion posts and Rotary Clubs in several states have taken an active part in recruiting pupils. Organizations like the Citizens' Bureau of Cleveland and the League of Foreign-Born Citizens of New York City maintain special classes for would-be citizens. The expensive problem of reaching mothers who cannot leave their immediate neighborhoods has been successfully dealt with in many cities by International Institutes of the Y. W. C. A., in Delaware by the Service Citizens (a private foundation) and in New York by the Education Committee for Non-English-Speaking Women; some of the New York Settlements have specialized in teaching mothers in their own homes. The Council on Immigrant Education, New York City, through studies of schools, stimulation of teachers and the setting-forth of immigrants' points of view, has made a definitely helpful contribution to this city's exceedingly difficult problem.

HEALTH EDUCATION

BY CHARLES H. KEENE, M. D.

DIRECTOR OF PHYSICAL EDUCATION, UNIVERSITY OF BUFFALO

Concepts of Health Education.—The interest in this subject has increased greatly since 1919. At least two concepts of the meaning of the term are rather common. The first of these includes under this title all the factors relating to health and health teaching in the schools and universities. The general scope of the school health program is comprehensively discussed in the Report of the Advisory Committee on Health Education of the National Child Health Council. (U. S. Bureau of Education, *School Health Studies No. 1, 1923*, Wash.)

The second concept confines the use of the term Health Education to that part of the program which relates directly to the teaching of hygiene—a better name for which would seem to be "health training and instruction." In this field the great emphasis has been upon the foundation of good health habits—to teach how to live healthfully. This cannot be done without the regular, routine practice of acts which have a definite good effect on the health of the individual and of the community. A few states—notably Connecticut and Pennsylvania—working through the state departments of Education, and several cities have issued definite graded courses of study in this field. In addition to this, the National Tuberculosis Association has drawn up a detailed graded plan. (Dansdill, *Health Training in Schools*, Nat. Tuberculosis Assoc.) The best and most effective publication has been the report of the Joint Committee on Health Problems in Education of the National Education Association and of the American Medical Association. (*Health Education—A Program for*

Public Schools and Teacher Training Institutions. Wash., Nat. Educ. Assoc.) Most helpful annual conferences on "Health Education" are being held in different sections of the country under the auspices of the American Child Health Association. (The annual report, N. Y., Am. Child Health Assoc.)

Ventilation of Schoolrooms.—In matters relating to the sanitation of the school plant, lighting and ventilating are most to the fore. Ventilation of school buildings was thoroughly studied by the New York Commission on Ventilation. Their Report showed that the health conditions in classrooms, as shown by the sickness rate, were considerably better in those rooms ventilated by open windows and an exit duct for foul air. The conditions under these circumstances were so much better than they were in those classrooms ventilated wholly by the fan system —with windows closed—that the predilection of many health workers for the open window system of ventilating seems wholly justified. It would seem that the enormous sums spent each year in installing fan ventilating systems in public schools might well be saved. The American Public Health Association at its annual meeting, (St. Louis, Oct. 19-22, 1925) adopted a resolution condemning the fan system of ventilating school buildings, and advocating the use of the open window and exhaust duct method.

School Health Supervision.—In the field of health supervision (the medical inspection, examination, and treatment of school children), the effort is to secure more careful and effective examinations and thereby bring about a larger percentage of correction of the physical defects found. The Committee on School Health Problems of the American Public Health Association is making special efforts along this line, with a view of securing some uniform method of examining for and reporting the physical defects of school children. (See the *Report*, Am. Pub. Health Assoc.) The tendency to place this phase of education directly under the control of Boards of Education is strong. The rapid increase in the number of special classes for those pupils having physical and mental defects that are more or less permanent, the strenuousness of athletics and of other phases of physical education, the rapidly growing concept of the place of the health of teachers in the school health program, and the just dawning appreciation of the relation of all these to mental hygiene, make such a definite placing of responsibility in the hands of educators essential. *U. S. Bureau of Education, Educational Hygiene: Bulletin*, 1923, No. 33.

Physical Education. — The large percentage of correctible physical defects found in young men at the time of the World War stimulated a lively increase in interest in physical education. While in 1919 only fifteen states had laws making compulsory the teaching of physical education, at the present time thirty-two states have such laws. Fifteen states require full-time supervisors of physical education, working under the auspices of the State Departments of Education. The tendency is away from formal gymnastics and toward play and team games. The present ideal is a type of physical education which shall reach every pupil every day.

Athletics of the interscholastic and intercollegiate type is being seriously criticised and its value questioned. The dollar-making phase of these contests has become exceedingly prominent. Enormous sums are being spent for stadiums in connection both with schools and with universities. This has gone to such an extreme that, in education at least, the present time is likely to become known as the "era of stadium building." Efforts to finance these have made winning a commercial asset, and the whole spirit of competition tends to become professionalized.

In the universities there is a strong trend toward a consolidation of all the activities relating to the physical welfare of the students. This means a combination, under one head, of the health service, the physical education activities, and all athletics. With our present bruising, tearing football enjoying such a vogue, the care of athletic injuries alone has become a complicated and expensive problem. Consolidation and greater coördination are the trend.

In general, the main effort in physical education has been to work out some scheme which shall offer opportunity and create desire for every pupil and student to exercise properly each day, and, with this, to build up some system whereby the effectiveness of the training may be tested. There are several ways of doing this. There are the motor ability tests sent out by a special committee of the American Physical Education Association (*Am. Physical Educ. Rev.*, Dec. 1924, p. 579.) Another plan is that of combining physical and scholastic tests (*Ibid*, Oct. 1924, p. 447.) A more complete plan is that used in the public schools of Philadelphia, where accomplishments in physical power, in health habits, coöperation in securing removal of physical defects, scholarship, and sportsmanship are the bases on which judgment rests. (*Mind and Body*, May 1925, p. 529.)

Sex Education.—In sex education the effort is to correlate more closely with the rest of the health teaching and training. The establishment of special clinics by municipal and state health departments has been a forward step. The United States Public Health Service, through its *Social Pathology,* issued to aid coöperative work with the state health departments, has rendered a distinct service to the problems involved in education relating to the control of venereal disease.

So far as sex education in the public schools is concerned, its progress has been held in check, partly by the attitude of certain religious groups which fear that it may lead into the field of birth control, partly by the attitude of the public, especially the parents; and partly by the attitude of the teachers. Many of these oppose it, both because of their feeling that they cannot take on additional burdens, and because they dread to try to teach a subject concerning the proper subject content and pedagogical method of which they know so little. The present effort is to correlate quite definitely this subject with the teaching of other school subjects, particularly biology and physical education. The methods advised are discussed in detail in a publication put out jointly by the United States Public Health Service and Bureau of Education. *High Schools and Sex Education* (U. S. Public Health Service, 1922).

At the present time, the true need in this field is to secure adequate instruction in the normal schools and in other teacher training institutions. It is essential that a generation of teachers be trained in the fundamentals of biology and the relations of sex to mental and physical health before proper instruction in sex education can be given safely and sanely in the public school. Always, such instruction should be given by members of the regular faculty of the normal school in question—not by itinerant lecturers.

The activites of the Interdepartmental Social Hygiene Board (*A. Y. B. 1919*, p. 806) have been transferred to the United States Bureau of Education and to the United States Public Health Service, and the Board itself has been discontinued.

The whole educational field in health is being profoundly influenced by popular literature, particularly the health articles appearing in such periodicals as *The Nation's Health* (Modern Hospital Publishing Co., Chicago), and *Hygeia* (The American Medical Association, Chicago). The health of college students is greatly affected by the deliberations and reports of the American Students Health Association. The outstanding publication of the year in the health education field is probably, *A Health Survey of 86 Cities,* (N. Y., Am. Child Health Assoc., Research Division).

PRIMARY AND GRADE SCHOOLS

By John K. Norton

National Education Association

Below are some of the outstanding educational developments of 1925 affecting elementary schools. Many of these did not begin in 1925. Progress in the directions indicated, however, were sufficiently distinctive to deserve emphasis. Limited space precludes detailed illustration of the developments cited.

Curriculum Revision.—The teachers of the nation are revising the elementary school curriculum. During 1925, 300 cities enrolled in the Cooperative plan for curriculum revision of the National Education Association. This movement has come to stay. It replaces the sporadic attempts at curriculum revision characteristic of the past. Many communities are creating permanent organizations responsible for continuous study and revision of their "courses of study." Among a few of the larger phases of this movement are:—

Emphasis on Character and Health Education.—The school is placing emphasis on training for character more than ever before. New courses attempt to make every subject one which contributes to moral development. A Committee of the National Education Association completed a nation-wide survey of this movement.

Physical as well as intellectual and moral development is being given by progressive school systems. The report issued by the joint committee of the National Education Association and the American Medical Association had a stimulating influence on this movement.

Text Books.—The text books of the past, dependent upon the reputation of their authors for acceptance, are giving way to those based upon scientific knowledge growing out of research.

Study of the Child.—Scientific study of the laws that govern the development of children's mental, physical and emotional life is leading to more skillful teaching. Studies of the pre-school child such as that of Bird Baldwin at Iowa State University have proceeded to the place where they promise fundamental revision of our knowledge of the effect of the pre-school age upon later development. The old lock-step system of classifying children rapidly gave way before more flexible methods of classification, based upon better knowledge of individual differences. Homogeneous grouping, and the Dalton and Winnetka plans, looked upon with increasing favor, contributed much to this movement.

Reorganization of School Units.—An important educational commission was created to determine the particular school organization that will function most effectively in educating children. The kindergarten is coming to be looked upon as an integral part of the elementary school. Better results both in the kindergarten and in the early primary grades are being obtained as a result. The Platoon School plan of elementary school organization is being adopted in many cities. It attempts to set up a threefold program of education—work, study and play. The Junior High School is replacing the old 8-4-4 type of organization. It calls for a 6-3-3 plan, that is, a six-year elementary school, three-year junior high school, and a three-year senior high school.

Better Teachers.—New curricula, plans of classification and organization in themselves accomplish little. They are valueless unless a capable teacher translates them into the lives of children. This fact is expressed as follows. The movement to bring all teachers up to at least a minimum standard of training proceeded with increased vigor during 1925. In Missouri 16,000 teachers enrolled in summer school courses. The movement for better trained teachers apparently is not a transient one. Accompanying the increased demands made of teachers, salary schedules are being lifted to a professional level.

This movement is general. In Chicago a committee of laymen brought in a report recommending a scale of teacher compensation far above schedules now in operation. The foundation is being laid upon which a real teaching *profession* may be founded and developed.

New Science of Education.—For the first time there are clear indications that the results of educational investigation are reaching the rank and file of teachers. The year 1925 indicates that scientific research will have as profound influence upon educational progress in the next fifty years as the investigations which Pasteur initiated a little over a half century ago have had upon medical development.

PROGRESS OF SECONDARY EDUCATION

By Thomas W. Gosling

Superintendent of Madison (Wis.) Public Schools

New Committee.—The year 1925 has witnessed several noteworthy achievements in the field of secondary education. The most important of these resulted from the initiative of the United States Commissioner of Education in organizing a National Committee to articulate the efforts of independent organizations working in the secondary field. The North Central Association of Colleges and Secondary Schools, the National Association of Secondary-School Principals, and other similar organizations were invited to nominate representatives who would constitute a new committee to study the problems of the American high school. This body bids fair to make a contribution as distinctive as that made several years ago by the Commission on the Reorganization of Secondary Education.

Curriculum.—The most pressing problem now before high-school teachers and administrators relates to the reorganization of the curriculum. Numerous independent investigators are working upon this problem. The place of the classics in the high-school curriculum is brought again into the focus of attention by the investigation which is in the making under the auspices of an association of teachers of the classics. A thorough study of the whole status of this subject is about to be determined so far as the present investigators are concerned. The scope of the investigation has been widened by the inclusion of a trained psychologist who will apply the results of studies in psychology to the problem in question.

Entrance Requirements. — At its annual meeting in March, the North Central Association of Colleges and Secondary Schools renewed its recommendations to colleges and universities that they revise their entrance requirements in such a manner as to permit students to enter college on the basis of units of work accomplished in the tenth, eleventh, and twelfth grades. Three great universities—the University of Michigan, the University of Nebraska, and the University of Missouri—already have made the suggested adjustments. If the other colleges and universities follow the same course it will not be long before the ninth grade will be as independent of the colleges as the seventh and eighth grades already are.

The Safety First Movement.—This already has had considerable development in elementary schools and is now to reach the high school. Interest in this important subject is exemplified by the action of the National Safety Council and of the National Society for the Study of Education in forming a joint committee to publish a yearbook under the auspices of the National Society for the Study of Education on the subject of *Education in Safety.* In this yearbook considerable attention will be paid to methods of instruction in the high school.

Size of Classes.—Another important problem of high-school organization relates to the size of class. Long accepted convention has set a standard for the high school far below that which elementary schools have been obliged to accept. The increasing costs of instruction have brought forcibly to the attention of administrators the expensiveness of the small class. Realization of this situation has lead to significant investigations of the relative merits of the small class and the large class. The most important of these investigations has been reported within the year by Professor P. R. Stevenson of the Ohio State University. This report shows that although no final conclusion can be stated, the trend of the investigation is in favor of the effectiveness of the large class. If later investigations prove this conclusion to be correct, it will be possible to reduce considerably the cost of instruction in the high school. The consensus of opinion is that American secondary education is about to undergo marked reconstruction. The achievements of the year point definitely in this direction.

Bibliography. — Two significant books relating to high-school education have appeared within the year. One is by Philip W. L. Cox on *Curriculum Adjustment in the Secondary School.* The other is by Willis L. Uhl on *Principles of Secondary Education.*

COLLEGES AND UNIVERSITIES

By Frederick B. Robinson

Dean, School of Business, College of City of New York

Increased Attendance.—The remarkable increase in attendance at American colleges and universities which began before the World War continued even more strongly after the War and through the period from 1920 to 1925. While no consistently kept statistics have been issued each year by any competent body, it is safe to estimate, from evidence derived from various sources, that there are now approximately half a million students in colleges, universities and professional schools in the United States. This great increase is partly due to the development of the public high schools throughout the country. The number of boys and girls completing high school courses of study which qualify them for college entrance is ever increasing, and state laws which require attendance at school during the years of high school age are becoming more and more numerous. But this is not the only reason for the increase in college students; it is also due to a genuine appreciation of the importance of higher education by many people who did not have the "college tradition" in the family.

During this period there has been a very conscious examination, by faculties and trustees, of the real functions of institutions of higher learning in the community, and various movements for improving the services of colleges have been inaugurated or have made considerable progress. Possibly the very increase in student attendance has made more necessary the solution of some of these problems.

Entrance Requirements.—The first is that of selecting students. While some institutions have attempted to meet the problem of overwhelming numbers by exclusion through the raising of college entrance standards, the vast majority have been setting their standards on a continually higher plane for purely educational reasons. The wide variation in the number of credits required for entrance which formerly existed has gradually disappeared and very few institutions accept students with less than the standard fifteen college-entrance credits. Coupled with this fairly uniform quantitative requirement, there have been worked out more flexible and satisfactory adjustments of the details of entrance subjects with the offerings of high schools; so the students from the public high schools can more easily go into the colleges.

Intelligence Tests.—During these five years, the use of intelligence tests has been gradually developed in technique and the number of institutions using them has increased. Some colleges had hoped to use intelligence tests as the basis of selecting students who would give promise of actually completing their college courses. It was felt that this would be a means of saving the waste which arises through incomplete courses. Others thought that the intelligence test would serve in place of high school grades or entrance examinations of the traditional sort. At present the tendency is to use intelligence tests as a supplementary means of grading students on entrance. The data obtained is preserved and checked with the college record subsequently made. It is hoped that, after a number of years, sufficient correlation material will be secured so as to enable conclusions to be reached concerning the application and validity of the tests.

Accommodations.—The increase in number of students has also made the various institutions study more carefully physical accommodations. Considerable progress has been made in college architecture, the arrangement of college rooms and laboratories and the oganization of facilities in general. Some institutions located in cities have been making experiments in the direction of tall "skyscraper" buildings on relatively small space, instead of low buildings spread out on an ample campus.

Teachers.—The selection of teachers has also become a very difficult matter. In order to avoid classes too large for good teaching, institutions have been forced to increase their staffs very rapidly. Obviously the problem of teacher training and teacher selection for higher education has been acute. Institutions which are favorably located have solved this problem to a certain extent by engaging as teachers on part time persons who are working in the various professions related to the subjects involved.

Programs.—A most significant development has been increased acceptance of the proposition that a college course of study is not merely a traditional grouping of subjects, but, rather, an intellectual training which bears a definite relation to the changing conditions of life. Curricula have been under constant scrutiny and there have been revaluations of various subjects in the curricula. College faculties are studying life pursuits of their various graduates and trying to arrange curricula which will have very definite relationships to the functions later to be performed by graduates. There is now a tendency to stiffen up the first two years of college courses and to permit of rational specialization in the last two. It is expected that in the Freshman and Sophomore years the disciplinary and foundational training begun in the high shcools should be completed. This is the work of junior college grade. Specialization in the Junior and Senior years becomes very definite for students who are inclined in certain professional or vocational directions.

Honors Courses.—For the general cultural students of superior ability "honors" courses have been suggested. During the last five years, such courses have been introduced in many institutions. Students in honors courses are not required to attend formal lectures and classroom exercises according to schedule, but are allowed a wider range of freedom for original work in certain general fields approved by the faculty. Their seminars, essays and reports are supervised more in accordance with the English tutorial system than the American method of recitation and lecture. These courses are expected to develop the student as an individual scholar of initiative and resource.

Groupings.—Methods of teaching related subjects are receiving more and more attention in institutions of higher learning. There is a tendency to break down the artificial barriers between departments, so that the social sciences and history are taught more as a unit, the languages are more completely inter-related, and the scientific subjects and mathematics are taught more as functioning groups than as separate entities.

International Education.—American colleges and universities have, since the war, shown increased interest in international education. The American Council on Education, which was organized in 1917, has gradually become a general clearing house for higher education in the United States, It has shown especial interest in international affairs. The Council now has an Associate Director who devotes his whole time to international affairs, the gathering of information concerning opportunities for study in all countries, the promoting of exchange of students and the checking up of credits or scholastic equivalents in all countries. At present the American University Unions in London and Paris, formed in 1917, are operated as a division of the American Council. The Institute for International Education, established in 1919, is also interlocked with the Council, and practically all matters of international education are guided directly or indirectly by the American Council. A large number of graduate students and professors are exchanged. During the last two years a new move was inaugurated in the direction of having undergraduates spend their Junior years abroad, with full credit toward their American degrees at home.

Gifts.—During the last five years, gifts on an unprecedented scale have been showered upon endowed institutions and the appropriations made by states and cities to publicly supported institutions have been steadily increased. This has been fortunate, for professional salaries were in danger of falling far below the proper and necessary living level. Additional funds have made salary increases possible and have saved many to the profession of teaching, but professional incomes are now relatively lower than they were twenty to thirty years ago.

Professional Schools.—In the field of university development, the most noteworthy advances have been made in the fields of medicine, law and business. The standards and equipment of medical schools have increased in a most satisfactory way. Furthermore, new facilities have been provided. Standards of admission to law schools, and the requirements for graduation have been steadily improving, largely due to the activities of the legal profession itself. While various new schools, such as those in journalism, arts and education, have been developed in different institutions, the largest developments seems to have been in the field of business. American business is now so complex and calls for so thoroughly a trained man, that universities have, during the last five years, done much in the way of providing additional undergraduate and graduate instruction in business.

Urban Institutions. — Cities are paying more attention to adult education. There are now over thirty-eight colleges and universities of high standard located in large cities which are offering at night not merely the standard courses in various schools available for day students, but also a wide range of special courses, short courses, lectures and other educational advantages to persons who are employed by day. This purposeful program in the field of adult education is considered by many the most promising educational sign in America at this time. This year the Bureau of Education at Washington, for the first time, established the office of Specialist in Adult Education.

Federal Organization.—During the last five years, colleges and universities have been interested in the movement to change the Bureau of Education at Washington into a federal department with a Secretary at its head who will have a place in the cabinet. The American Council on Education, which, more than any other single agency expresses the general opinion of colleges and universities throughout the United States, has expressed itself as favoring such a Department of Education. But it has not supported any of the various measures that have been drawn up and presented to Congress. No measure has yet been drawn up which has not received bitter opposition, either because of large appropriations which were included in its provision or because of some of the powers and duties assigned to the new department.

PROFESSIONAL SCHOOLS

By Arthur H. Daniels
Dean of Graduate School, University of Illinois

Dentistry.—The significance in dentistry of a fuller introduction of the academic spirit in professional schools means that the subject is making its place more secure as a profession rather than an occupation or mechanical trade. The two leading factors in this movement have been the connection of dental schools with universities and the requirement of some college work. Not many years ago the majority of the dental schools of the United States were privately owned and administered. Now three-fourths of them are either organized parts of universities or are in process of organization under university control and management. Closely related to this fact has been the requirement of one year of college work. In 1925 a number of university dental schools voted to require sixty semester hours of pre-dental training for admission to the dental curriculum. In 1926 this will be one of the Dental Educational Council's minimum requirements for a Class A rating.

An outstanding feature of the year has been the organization of graduate work. Graduate courses in orthodontia, oral surgery and other specialties which meet the standards of the best graduate schools have been established in several of the leading schools. Research in these branches, together with the development of children's clinics promises important advances in dentistry as a mode of health service. Children's clinics afford the necessary training for dentists who are prepared to practice children's dentistry. Of the importance of this branch of dentistry, Dean Moorehead of the College of Dentistry, of the University of Illinois writes, "The proper care of the mouth of the child by qualified specialists will prevent much of the dental trouble of adult life, not only by training the child in the care of the mouth and teeth, but in the preservation of the deciduous teeth in a state of health which permits the permanent teeth to come into a wholesome territory."

Law.—Perhaps the most significant trend in the development of the law schools of the country is manifested in the number of those which have increased the amount of preliminary college work as an admission requirement. In 1921, the number of full-time law schools—schools in which students devote substantially all their working time to their studies—was thirty-one. In 1925 this number was increased to sixty-five. Twelve full-time schools require more than five years of study after the high school to complete the course. The requirement of at least two years of study in college was made a condition of membership in the Association of American Law Schools after September 1, 1925. This Association, together with the American Bar Association with its "Council on Legal Education and Admissions to the Bar," have been important influences in the movement to increase the amount of preliminary college work.

The influence of this movement is also seen in state legislation. The state of West Virginia has adopted a requirement for all candidates for admission to the bar in that state of two years of college work, or their equivalent, followed by three years of law-school study. In Illinois there has gone into force the requirement of one year of college work, or its equivalent, prior to the beginning of the candidate's law study. And the announcement has been made that applicants in Illinois beginning their law studies after July 1, 1926, must present the equivalent of two years of college work. The states of West Virginia and Illinois, together with Kansas, which recently adopted a two year requirement, are the only ones which have as yet approximated the recommendations of the American Association.

Medicine.—Several of the best established medical schools are well equipped for scientific research and have taken up advanced work in the spirit that has manifested itself in the development of graduate work in the leading universities of the country. Epoch-making discoveries—of insulin and more recently of the cause of scarlet fever—have given a marked impetus to investigation in the medical sciences. It would seem as if the growth of interest in this line of medical study has been the occasion for alarm in the minds of some physicians and laymen lest our medical schools devote too many of their energies and resources in training specialists to the neglect of general practitioners. And closely connected with this is the claim that a serious shortage of physicians now exists especially in the rural districts of the United States. A survey conducted under the auspices of the General Medical Board of the Rockefeller Foundation does not support this claim. Fortunately there are leaders in medical education who are strong advocates of research and are equally emphatic in advocating the training that tends to make the physician a careful student of the patient. They do not regard training in research as valuable to the specialist only. In the words of an eminent English physician, "If every student became an investigator and discoverer, the science and art of medicine would be saved from perfunctory workmanship."

A decided trend in the field of medicine is the attention that is being given to the prevention of disease. A striking illustration of this is seen in the plan to develop Tropical Medicine in New Orleans. It is entirely a University development. Dr. Aldo Castellani, the eminent Italian authority on tropical diseases, has recently arrived in this country to assume the headship of the Department of Tropical Medicine in the School of Medicine of Tulane University, and a full professorship in the subject. The favorable location for this enterprise and its inauguration at this time are highly significant from the standpoint of needed improvement of hygienic conditions in southern parts of this country where extensive migrations are taking place. Much is to be expected from this movement.

TRAINING AND TENURE OF TEACHERS

By Harry S. Ganders
Professor at the Colorado State Teachers College

TEACHERS' TENURE

Reasons for sound tenure laws are: to decrease teacher turnover, to stabilize the profession, to protect teachers from unfair dismissals, to provide for dismissals of incompetents, to encourage professional growth, and make the profession more attractive.

Information.—The facts pertaining to teacher tenure in the public schools of the United States were secured during the year 1924 by the N. E. A. Committee of One Hundred—Fred M. Hunter, Chairman. Data was secured from state superintendents, state-wide surveys by teachers' associations, and by the U. S. Bureau of Education. Turnover ranges from 4% to 47% with an average of 16% for the nation. Rural turnover within states is as high as 68%. The average tenure for superintendents is three years. The policy of hiring and firing at will still prevails.

The fact that Germany, Denmark, Switzerland, Netherlands, Finland, Norway, Sweden, Great Britain, and France have tenure laws is being used as an argument in favor of teacher tenure in this country.

Legislation.—In 1925, four states —California, New York, New Jersey, and Montana—have tenure laws of practically state-wide application. In Colorado, Illinois, Louisiana, Oregon, and Wisconsin the law applies only to certain large cities while in Maryland and Massachusetts only Baltimore and Boston are excluded. Certain cities in twenty-two states now have local tenure regulations. Six states are now working for amendments to their laws, and in January, 1925, nine states—Illinois, Minnesota, Nevada, New York, Ohio, Pennsylvania, Virginia, and Washington—were waging campaigns for the enactment of tenure legislation.

In several states, courts of final jurisdiction have recently held that teachers cannot be legally dismissed because of marriage.

College Tenure.—Although tenure is supposed to be more secure for college teachers, only one-third of the professors in six representative colleges who were on the faculties in 1920-21 retained their positions in 1923-24. In 1925 the N. E. A. Committee of One Hundred studied the problems of tenure in normal schools and teachers' colleges. They reported that in 107 such institutions, teachers are appointed but for a single year. Turnover ranges from 8.5% to 12%. Teachers are given notice prior to dismissal, but seldom is legal redress sought. Practically none of the states have tenure laws pertaining to faculties of normal schools and teachers colleges.

TEACHER TRAINING

Requirements.—In addition to high school graduation, certain health and character requirements are being required for entrance to teacher training institutions. By 1925, in New York State waiting lists were established and undesirable students were not admitted.

Several states are putting into effect stringent certification laws, e.g., by 1927 no teacher can teach in Pennsylvania who does not hold the equivalent of a normal school diploma.

If two years of training above high school classifies a teacher as "trained," states have increased the percentage of trained teachers during the interim 1919 and 1925, as follows: Pennsylvania, 28% (largely due to Edmons act resulting from the leadership of Thomas E. Finegan); North Carolina, 27%; Maine, 19%; Oregon, 16%; New Hampshire, 13%; Wyoming, 15.5%; Virginia, 11%; Ohio, 19%. According to W. C. Bagley, ranking states with respect to the proportion of trained teachers in 1924-25 were: Massachusetts, 90%; Arizona, California, Rhode Island, Connecticut, New York, and New Jersey, 80% or more; Pennsylvania, New Hampshire, Oregon, 70% or more; Michigan, Maine, and Washington, 60% or more; Nevada, Delaware, Minnesota, Ohio, and Wisconsin, 55% or more.

Increased Period.—A current trend is toward a longer period as well as higher quality of training. There are twenty-eight fewer two-year normal schools now than in 1920, and more than fifty more teachers' colleges. Tendencies toward improvement of teacher training is seen in the growing emphasis upon practice teaching. At the University of Cincinnati, three years of professional training follow two years of regular A. B. college work. This year the Board of Trustees at Colorado State Teachers' College, on the recommendation of President G. W. Frasier, created the position of "Supervisor of Collegiate Instruction."

Summer Training.—The increased number of teachers enrolled in the 1925 summer sessions was phenomenal. Lack of capacity caused the Buffalo State Normal School to turn away 150 prospective students. However, during 1925, twenty-five different states were forced to train rural teachers in teacher training departments of secondary schools. The junior college is advocated by some as still another makeshift.

Associations.—"In service" training has been furthered this year by more and better teacher associations (the N. E. A. now has a membership of more than 150,000), by bonuses for summer school attendance, by development of extension departments, through teacher participation in curricular and administrative functions, through visiting days, and through the establishment of demonstration schools such as the Monument Experimental School at Trenton, New Jersey, and the Helping Teacher Schools in Maine. Systems of sabbatical leave are well established in many leading cities.

Specialization.—Each year teacher training is becoming more specialized. Teachers must now be trained for particular services at given levels (e.g., kindergarten, primary, etc.). Serious problems grow out of these demands. Just what are the particularized duties of various types of teachers and school officers working in various specialized situations must be determined through job analyses. This problem is being attacked by W. W. Charters with the aid of a subvention from the Commonwealth Fund. Other institutions are making similar studies. L. B. McMullen has just found that the average teaching load of 2500 teachers in seventy-five teacher training institutions is approximately forty hours per week.

INTERNATIONAL EXCHANGE OF TEACHERS

BY DAVID ALLAN ROBERTSON

ASSISTANT DIRECTOR, AMERICAN COUNCIL ON EDUCATION

The large American interest in international education relations has been a discovery of 1925. The American Council on Education printed in the *Educational Record*, April 1925, a list of 115 organizations in the field. Mutual acquaintance has already led to mutual confidence and a desire for coöperation. A conference of these bodies has been called for February, 1926. Meanwhile, progress in this direction has already been made by the following bodies: the American Council on Education, which is the representative of 15 great educational associations and 195 universities and colleges; the American University Union with its offices in London and Paris; the Institute of International Education; the American Association of University Women; the Carnegie Corporation; and the Laura Spelman Rockefeller Memorial. The Council has taken over the American University Union, constituting the former Trustees of the Union as a Committee on International Relations. The Institute of International Education has become a member of the Council, its trustees are now nominated by the Council and it becomes an administrative agent of the Council. In Paris and other centers abroad there is a desire to coördinate the numerous independent American efforts in education abroad.

An American Committee on Intellectual Coöperation has been formed by Dr. R. A. Millikan, American member of the League of Nations Committee on Intellectual Coöperation, including many eminent educators and public persons.

International exchange of students and professors.—Academic reciprocity, hitherto represented only by the Rhodes Scholarships, the American Field Service Fellowships, Franco-American Fellowships, Chinese Indemnity Scholarships, American-Scandinavian Fellowships, American-Hungarian Fellowships, American-Czechoslovak Fellowships, International Education Board Fellowships, Rockefeller Foundation Fellowships, Laura Spelman Rockefeller Memorial Fellowships, and a large number of individual fellowships and scholarships, has been greatly increased in importance by the establishment of the *Commonwealth Fund Fellowships* founded to develop international understanding especially between the two great English-speaking nations of the world; it provides for the appointment of 20 British Fellows each year, each to pursue two years of study in graduate schools of the United States. The stipend, approximately $3,000 each year, provides for traveling expenses to and from the American university, tuition and other fees, living expenses, and provision for travel in the United States during holidays. The Secretary is Mr. R. H. Simpson, 50 Russell Square, London W. C. 1. Another important addition of 1925 is the *John Simon Guggenheim Memorial Foundation* established by Senator and Mrs. Simon Guggenheim in memory of their son. These fellowships are open to Americans without regard to age, sex, race or creed. Candidates must have demonstrated unusual capacity for productive scholarship or ability in some one of the fine arts and must present definite and practical plans for foreign study. The normal stipend is $2500. The Secretary is Henry Allen Moe, Pershing Square Building, New York.

Committee on Foreign Travel and Study.—Believing that a large body of American students not eligible for international fellowships nevertheless may become leaders in business and politics, a new organization has been formed, of which Senator Coleman DuPont is Chairman; it seeks to find a way for undergraduates to study abroad without interrupting progress toward their American degrees. For this Committee President Frank Aydelotte of Swarthmore College and Mr. Marcus M. Marks made investigations in Europe in 1924, and in 1925 the Assistant Director David Allan Robertson of the American Council on Education made further arrangements (nine scholarships of $1000 each) with British and European universities, which have already proved the feasibility of highly selected American students after two years in an American college entering foreign universities for a third year, securing credit for this work on return to their own universities and graduating with their class.

The 1924 Immigration Act.—This had unexpected and wide influence on the colleges. Because the quota system resulted in diminished use of space in steerage quarters of Atlantic steamships, the companies reconstructed steerage accommodation and offered a low rate to students in "Tourist Third Class." Advantage was taken of this new class in the summer by 18,809 persons, mostly students. Efforts of the American Council on Education have led to an offering of similar opportunity for travel in South America in 1926.

Registration.—In 1924-5 the American University Union listed 425 American students registered in universities of England, Scotland, Ireland and Wales, of whom one-fourth were on scholarships, including Rhodes scholarships. In France in 1924-5 the Paris office of the American University Union reported 3789 American students (1558 men, 2231 women). Of these 694 were in the University of Paris and 452 in regular and summer sessions in provincial universities. The Commissioner General of

Immigration reports that from January 1, 1925, to September 30, 1925, 1416 foreign students were admitted to the United States, not including students from North and South America. In 1923-24 there appear to have been in the United States 6988 students, from 100 countries, in 400 institutions, of which 36 had 50 students or more.

Important publications include:—articles in the *Educational Record*, especially that of April, reprinted for general distrbution under the title: D. A. Robertson: *International Educational Relations* (*Bulletin of the Institute of International Education*). Among these publications is a list of scholarships and fellowships abroad for American students, and a list of fellowships in the United States open to foreign students.—*The World Missionary Atlas*, edited by Harlan P. Beach and Charles H. Fahs (Institute of Social and Religious Research, N. Y., 1925).—*The Foreign Student in America*, edited by Reginald Wheeler, Henry H. King, and Alexander B. Davidson (Association Press, N. Y., 1925).—*Educational Yearbook of the International Institute of Teachers' College*, edited by I. L. Kandel (N. Y., Macmillan, 1925).—*Report on Higher Education in Japan and China* by Dr. Yoshi S. Kuno, issued by the Bureau of Education.—*Education in East Africa*, published by the Phelps-Stokes Fund in 1925; the *Bulletins of the International University Information Office* maintained by the League of Nations Committee on Intellectual Coöperation appeared regularly during its second year.—*Minerva, 1925*, a volume of 1942 pages resumes its pre-war bulk and importance as a compendium of information of the learned world.

STATISTICS OF ACADEMIC EDUCATION

BY JOHN K. NORTON

DIRECTOR, RESEARCH DIVISION, NATIONAL EDUCATION ASSOCIATION

COST OF EDUCATION [1]

Type of School	Estimated Total Cost	Type of School	Estimated Total Cost
Public elementary schools (including kindergarten)	$1,163,374,074	Universities and colleges	272,815,703
Public high schools	417,297,222	Teachers' colleges and normal schools	38,794,430
Private elementary schools	77,397,600	Other schools	50,763,410
Private secondary schools	32,808,053	Total cost of education	$2,053,250,492

Bibliography.—WHEELER, J. L., "Sixty Educational Books of 1924" (*Journal Nat. Educ. Assoc., Oct., 1925*).—WHEELER, J. L., "Educational Books of 1925."—*Record of Current Educational Publications;* also Library Leaflets and Reading Courses on a variety of subjects.—Yearbooks and research studies of professional associations (noted above) contain valuable bibliographies.

DIVISION XL
VOCATIONAL EDUCATION

CONCEPTS IN VOCATIONAL EDUCATION

By Charles R. Allen

Editor and Consultant, Federal Board for Vocational Education

CHANGES IN APPROACH

Concentration Upon Youth.—The concentration of educational service upon youth has always apparently been based upon the theory that youth constituted the coming asset of society; that youth was the formative period of the future citizen; and hence that education of any kind, to function most efficiently, must deal exclusively with youth rather than with adults. This concept as originally accepted in vocational education led to the concentration of effort and resources on preëmployment day vocational schools.

As experience has been secured, it has appeared more and more evident that effective social service is to be secured in proportion as more and more attention is paid to giving service to the group of relatively young people who have left the general school and have gone to work; and also to the employed adult who has already made progress in a chosen occupation, but who requires additional specific training and education in order that he may either do his work better or may prepare himself for promotion or for a better job in the line of his employment. This change in concept has appeared in practice in the development of continuation schools for employed youth, of evening extension courses, and other courses of special types for employed adults. Vocational education if it is to be the most socially effective must reach those who have already gone to work.

Gainful Occupation.—In vocational education, where the objective is always to secure doing ability, there has come about a complete abandonment of the notion of faculty psychology and a full acceptance of the concept that vocational education is concerned with the establishment, through adequate repetitive experiences, of habits of manipulation and of thinking, that function in those fields of social adjustment included in the term "gainful occupations." This changed concept has naturally led to profound modifications in organization and administration in the conception of what constitutes functioning content in the organization of content and in methods of instruction.

CHANGES IN METHODS

Organization and Administration.—Changed conceptions as to organization and administration have come about through a steadily increasing realization, based upon a wider and wider experience, that the problems of vocational education are so different from those of general education that totally different methods and devices must be developed, and that the methods and devices in use for the administration and organization of the general educational school of secondary grade, and, in fact, to a considerable extent of the college and university, are not applicable in many respects in this new field of education.

This changed conception has shown itself in practice in such devices as the short unit course; elastic conditions of admission; dull season courses for employed workers; development of provision for individual courses of instruction; and practical abandonment of the old class organization for the mass handling of learners.

Restriction of Content.—From a concept which essentially limited the scope of vocational education to the professions, to a few skilled trades, a few commercial occupations, a few needle arts, and to "general preparation for farming," the concept has steadily widened until today a program of vocational education is considered as potentially responsible for dealing with any occupation whereby men and women earn their bread, on either a preëmployment or an extension basis.

This broader concept has brought with it the recognition of the fact that for each occupation there is a specific body of content which does not function in any other occupation, though there may be certain "overlaps." Hence an enormous enlargement in the concept of specific functioning content possibilities, this concept in turn tending to do away with the theory of "occupational fundamentals."

The School as a Social Agency.—The old-fashioned school was a social agency divorced from actual life activities. Today the vocational school is conceived of as a social agency relying for its efficiency and its success largely on the coöperation and assistance of those occupational groups which it has undertaken to serve. It looks to those groups for its content, for its instructors, for its coöperation, and, in many types of organization, for the giving of a definite part of the vocational training. The development of the supervised home project in home making and in agricultural vocational education, and of the part-time apprenticeship course with the utilization of the apprenticeship commission, are two illustrations of the changed concept as to the relation of the school to real life activities.

New Objectives.—It is now recognized that vocational education has for its major objectives the training and education of an individual only in those skills and knowledges that make for success in specific occupations. This concept now distinguishes clearly between vocational education and such other desirable educational activities as prevocational education, manual training, industrial arts, and other educational activities of a concrete or "practical" type.

NEW STANDARDS

Academic.—The standards of the general education school of ten or fifteen years ago were academic. They were the recitation mark, the examination mark, the passing grade, or the ability to meet the entrance requirements to an institution of higher learning. Where the objective was to give actual doing ability to an extent prescribed by the standards of the occupation itself, the standards and tests of the general education schools failed to function in vocational education. Out of experience has come the conviction that the standards by which a vocational program must be judged, the standards by which the progress of the pupil must be determined, the standards upon which satisfactory training must be evaluated, must be different from those which are used in general education.

Alterations.—Let us briefly summarize the previous standards or characteristics of a proper general vocational program as understood nowadays:

(1) *Selected groups* must receive the instruction in order to be effective with vocational students.

(2) The *subject matter* to be taught must be such as directly functions in the work for which the pupil is being trained.

(3) *Instructors* must have been occupationally *trained* in the trade or *occupation* they are to teach.

(4) *Individual instruction* should be given whenever necessary to the progress of any member of the group.

(5) Each *individual* member of the group should be permitted to *progress* as rapidly as his or her ability will permit and pro-

motions should be made at any time on the basis of ability to do the work required.

(6) *Effective training* for work can best be given *on a real job.*

(7) *The order of difficulty* should determine all *subject matter* and training should be *arranged* in the most effective instructional *order of difficulty.*

(8) The pupil, while being trained, should be placed in an *occupational atmosphere* and environment.

(9) The instruction and training should be based upon *prevailing occupational standards.*

(10) *Repetitive training* in the various operations should be given such as will enable the learner to begin work as an economic asset rather than as an economic liability to his employer.

These characteristics or standards vary widely from those set up in general education, either under the doctrine of formal discipline or under the more modern theory of the establishing of appreciations.

RELATIONS OF THE FEDERAL GOVERNMENT TO VOCATIONAL EDUCATION

By J. C. Wright

Director, Federal Board for Vocational Education

ORDINARY FEDERAL AGENCIES

Bureau of Education.—The relation of the United States Bureau of Education to vocational education is only indirect, as it has no administrative responsibilities other than those connected with certain funds, including the Congressional payments to the land-grant colleges. The Bureau of Education is charged with responsibility for seeing that the money is expended in accordance with the law.

The Bureau is a fact-finding and a fact-disseminating Government agency. By this means it aims to foster and stimulate the cause of education in the United States. With reference to vocational education the Bureau attempts to promote the work of the land-grant colleges in agriculture, engineering, and home economics. It offers such assistance as its facilities will permit in the direction of the administration and organization of these lines of vocational education.

In connection with its work in higher education the Bureau of Education gathers statistics relative to collegiate courses in the various vocational lines, such as law, medicine, commerce, and engineering. These statistics deal with curricula, length of courses, entrance requirements, teaching equipment, and the organization of the work. The Bureau also makes numerous surveys in the field of higher education, calls educational conferences for those interested in promoting various lines of vocational education, and writes reports on many phases of vocational education, describing present practice and offering implications for improvement therein.

The Department of Agriculture in coöperation with State agricultural colleges and farm organizations conducts extension work through more than 4,000 State leaders and county agencies engaged in agricultural and home demonstration work. This work is done through field and home demonstrations, farmers' institutes, and other meetings, through visits to farms and homes, through exhibits at fairs, lantern slides, moving pictures, by telephone and by office conversations, and through correspondence.

Extension work carried on with boys and girls makes necessary the employment of more than 300 State and sectional county club leaders, together with the county agricultural and home demonstration agents, and the assistance of thousands of voluntary local leaders working in coöperation with the parents. Over 500,000 boys and girls were enrolled in this work in the year ending 1923, in community clubs classified according to activities, such as corn, pigs, poultry, or canning clubs.

The Department of Labor renders service through the Bureau of

Naturalization. Children's Bureau, Women's Bureau, and Employment Service. The Bureau of Naturalization encourages special exercises of welcome to new citizens, for young people attaining their majority, and furnishes suggestions for programs for such occasions. The Children's Bureau investigates and disseminates information upon all matters pertaining to the welfare of children and child life among all classes of our people. The Women's Bureau investigates matters and formulates standards and policies to improve the welfare, efficiency, and opportunity of wage-earning women. The Employment Service offers many opportunities for the placement of young people in better lines of employment in keeping with their particular aptitudes and training. The total field force engaged in the above activities numbers about 550 people.

FEDERAL BOARD FOR VOCATIONAL EDUCATION

Organizing Act.—Through an act of Congress approved by the President February 23, 1917 (now known as the Vocational Education Act or the Smith-Hughes Act), the United States established the principle that the Nation, as a whole, has a share of the responsibility for the vocational education of persons who have entered upon, or who are preparing to enter upon, a trade or industrial pursuit; for the work of the farm or of the home; and for the preparation of teachers of vocational classes. The act also establishes the principle that direct responsibility for carrying on the work of vocational education rests upon the States, without direct organization or immediate direction by the Federal Government or its agents.

Appropriations.—The Act provided substantial financial assistance to the States for the promotion of vocational education. The sums appropriated by Congress are to be allotted to the States in proportion which their population bears to the population of the United States, for the following purposes:

(1) Payment of salaries of teachers, supervisors, and directors of agricultural subjects. (2) Payment of salaries of trade, home economics, and industrial teachers. (3) Preparation of teachers of trade and industrial subjects, teachers of home economics subjects, and teachers, supervisors, and directors of subjects in the agricultural field.

Distribution.—The first appropriation is allotted to the States in the proportion which their rural population bears to the total population of the United States, the second in the proportion which their urban population bears to the total urban population of the United States; the third in the proportion which their total population bears to the total population of the United States. The annual minimum allotment to a State is $10,000 each. The total appropriation to the States for the fiscal year ending June 30, 1918, was about $1,500,000. This increased annually until for the fiscal year ending June 30, 1926, and annually thereafter, the total appropriation will be $7,184,901.51. The law further provides that each dollar of Federal money must be matched by at least another dollar of State or local money, all of which must be expended under the supervision and control of the State board. In 1925 the States expended $2.73 of State and local money for every dollar of Federal money. A total of $20,930,215 was expended in 1925, from all three funds.

Support of Teachers.—In addition to Federal funds provided for the encouragement of States in developing programs of vocational education, the National Vocational Education Act also provides Federal aid to serve a similar purpose in the training of vocational teachers. The framers of this act very wisely saw that if programs of vocational education were to be effective, teachers must be especially trained for this special form of educational work. During the year 1925 students were enrolled in the teacher-training classes as conducted under the various State programs.

Officials.—The Board for Vocational Education consists of seven members; three are appointed by the President. The other four are ex officio, viz.: the Secretary of Labor; the Secretary of Commerce; the Secretary of Agriculture; the Commissioner of Education; the three appointees are drawn respectively from manufacturing and commerce, agriculture, and labor.

The service to be rendered by the Federal Government through these coöperative agreements with the States and the Territory of Hawaii is given by a staff of 25 Federal field representatives, each one a specialist in some particular line. The total administrative staff with which the Federal Board deals directly in the several States includes some 600 supervisors, teacher trainers, directors, and State superintendents of public instruction.

Range of Investigation.—It is the duty of the Federal Board for Vocational Education to make, or cause to have made studies, investigations, and reports, with particular reference to their use in aiding the States in the establishment of vocational schools and classes and in giving instruction in agriculture, trades and industries, commerce and commercial pursuits, and home economics. Such studies, investigations, and reports shall include agriculture and agricultural processes and requirements upon agricultural workers; trades, industries, and apprenticeships, trade and industrial requirements upon industrial workers, and classification of industrial processes and pursuits; commerce and commercial pursuits and requirements upon commercial workers; home management, domestic science, and the study of related facts and principles; and problems of administration of vocational schools and of courses of study and instruction in vocational subjects.

Subjects of Investigation.—Under this program the Federal Board has included:

1. Analyzing the job of a home maker: to determine functioning content for training courses.
2. Assistance to States in establishing part-time continuation school programs.
3. Development of training courses in retail selling, in coöperation with National Retail Dry Goods Association.
4. Development of training courses for apprentices in railway shops and in other skilled trades.
5. The betterment of conference methods for the improvement of the work of minor executives.
6. The development of special teacher training for occupationally competent instructors and for foremen in industrial plants.
7. Developing more efficient methods of instruction in commercial education.
8. Development of part-time classes for employed girls and women.
9. Assistance to States in establishing State programs for civilian vocational rehabilitation.
10. The analysis and efficient use of functioning content in agricultural vocational education.
11. Establishing standards and improving the methods of civilian vocational rehabilitation in the States.
12. The promotion and development of special training courses for negro teachers of home economics.
13. Establishing and applying standards for vocational experience of teachers of home economics.
14. Reduction of the cost per case for efficient civilian vocational rehabilitation.
15. Development of a set of efficiency factors for agricultural education and rating the States on them.
16. The development and promotion of more efficient methods of instruction in agricultural education.
17. The promotion and development of part-time courses for farm boys who have left the regular high school.
18. Coöperation with the National Association of Retail Grocers in preparing a plan for training and in the preparation of material for instruction.

STATE VOCATIONAL TRAINING

By J. C. Wright

Director, Federal Board for Vocational Education

FEDERAL AID

Boards.—The State administrative agency provided in the act is a State Board for Vocational Education designated or created by the legislative authority of the State, each consisting of not less than three members, and endowed with the necessary powers to coöperate with the Federal Board for Vocational Education in the administration of the provision of the Vocational Education Act.

Allotments.—In order to secure an allotment a State must accept the provisions of the act through legislative authority, and the State Board must provide a plan of work for the State which is approved by the Federal Board. Each of the 48 States and the Territory of Hawaii at present has a State Board for Vocational Education which is coöperating with the Federal Board in the administration of this act. The State plans submitted annually to the Federal Board for approval must show the kinds of schools and classes for which it is proposed the allotment shall be used; the plan of administration and supervision to be followed by the State board; the qualifications of the teachers, the courses of instruction; the methods of instruction to be used; and the plans for training supervisors and teachers.

The State is required to designate the State treasurer as custodian for vocational education, to have charge of the disbursements of the funds. The duty of administering the funds is placed entirely in the hands of the State board.

Acceptance.—All 48 States and the Territory of Hawaii have accepted the provisions of the National Vocational Education Act and are coöperating with the Federal Government in promoting vocational education. The benefits of the Civilian Vocational Rehabilitation Act have been accepted by the legislatures of 39 States.

Federal Approval.—It is the duty of the Federal Board to examine these plans and approve the same if believed to be feasible and found to be in conformity with the provisions and purposes of the Federal Act. The Federal Board must certify on or before the first day of January of each year to the Secretary of the Treasury each State which has accepted the provisions of the act and complied therewith, including the amounts which the State is entitled to receive. Once the plan of the State is approved by the Federal Board the administration of the act in the State is in the hands of the State Board for vocational education.

VOCATIONAL SCHOOLS

Federally Aided Schools.—The National Vocational Education Act provides for three types of vocational schools: part-time schools, where those attending do so for a portion of their ordinary working time; evening schools, attended by those over 16 years of age on their own time, after the close of the working day; and all-day schools, which are attended by those who have no other regular occupation than attendance upon these schools. The different types of schools, with their various modifications, are included within the various fields of vocational education that are within the scope of the National Vocational Education Act; that is, vocational education of less than college grade for agriculture, trade and industry, and home economics.

Enrollment.—The Ninth Annual Report of the Federal Board for the year 1925 shows that the enrollment in these three types has increased as follows:

	1918	*1925*
Part-time schools	53,005	319,020
Evening schools	68,693	190,388
All-day schools	42,488	149,962
Total	164,186	659,370

Supervised Schools.—In addition to the above enrollment in *federally aided schools* there was reported for the year 1925, 115,737 enrolled in schools under the supervision of the State boards and which were organized in accordance with the State's plan, but for which no Federal funds were used. Several States have set up the policy of using Federal funds only for new programs and of shifting the burden of cost on the local community more and more as the program develops. We may expect to see this policy further extended in the coming years in view of the fact that the amount of Federal funds available to the States ceases to increase annually after 1926.

CIVILIAN VOCATIONAL REHABILITATION

Federal.—It can be fairly assumed that the intent of Congress in enacting the Civilian Vocational Rehabilitation Act of 1920 was twofold. The first objective was that of eliminating, as far as possible, human suffering and distress which inevitably follow loss of earning power caused by accident or disease, while the second purpose was that of conserving our human resources by reducing that group of our citizens whose earning capacity has been decreased or destroyed through such causes. It can be assumed, therefore, that the motives which actuated the passage of the legislation were both philanthropic and economic, but both were in the general direction of public welfare.

States.—The first basis upon which to estimate the progress which has been made is to ascertain the degree to which the States have entered into coöperation with the Federal Government under the terms of the act. Prior to the passage of the act only 6 States had inaugurated services of civilian vocational rehabilitation for the physically disabled. At the present time 39 have enacted legislation setting up coöperative relations with the Federal Board for Vocational Education as the representative of the Federal Government, and it is probable that at least 2 more will have enacted similar legislation within the coming year.

Purpose. — Civilian vocational rehabilitation means taking an individual who, through accident or disease has practically lost his earning capacity, and restoring him to an earning power. Abundant evidence has been accumulated to show that this can be accomplished in the great majority of cases. For illustration, in a recent study that was carried on in 36 States, covering the history of over 6,000 cases, it was shown that these individuals had been so restrained and restored to earning capacity that they were enabled to follow 628 gainful occupations, ranging from highly skilled and professional employments to relatively unskilled work of a remunerative character. Moreover, the 628 gainful occupations are the ordinary and usual occupations by which people earn their living. They do not include such occupations as are commonly connected with therapeutic work, and are kinds of jobs for which normal unhandicapped workers are carried on the pay rolls of employing establishments.

Expense.—As one result of this progress, it may be pointed out that it is no small achievement for the States, on the average, to have reduced the cost of rehabilitating the disabled worker, including all expenses of administration, to the average amount of $203 per case, which cost compares very favorably with figures for general or for vocational education. In other words, the cost of retraining compares very favorably with the cost of other forms of training.

Origin.—The civilian rehabilitation program was an outgrowth of that developed for the disabled soldier, sailor, and marine.* Experience had demonstrated that the disabled man with his vocational handicap was a potential liability, but that with his vocational handicap removed, even though he retained his physical disability he became an economic asset. The United States was the first country to undertake to establish a program of civilian vocational rehabilitation on a national scale. This had not been attempted by any European country. It is true that many of the European countries, noticeably Germany, had legislation involving compensation and various forms of relief, but this is as far as they had gone at the time of the passage of the National Civilian Vocational Rehabilitation Act.

---

* Organized in 1918 under the Federal Board for Vocational Education but transferred by Congress in 1921 to the United States Veterans' Bureau.

SEMI-PUBLIC AND PHILANTHROPIC SCHOOLS

By Frank Cushman

Chief, Trade and Industrial Education Service

GROUPS

Semi-public and philanthropic agencies are rendering an important service in the promotion of vocational education in the United States. The service rendered by these agencies supplements that which is being rendered throughout the country through public vocational schools organized as an integral part of the public school system. Semi-public and philanthropic institutions doing this work may be classified into two principal groups as follows:

(1) **Endowed institutions,** such as the David Rankin, Jr., School of Mechanical Trades, St. Louis, William Hood Dunwoody Institute, Minneapolis, Wentworth Institute and Franklin Union, Boston, Williamson Free School of Mechanical Trades and Girard College, Philadelphia.

(2) **Schools operated by social service agencies,** such as the Young Men's Christian Association and the Knights of Columbus.

The Isaac Delgado Central Trade School of New Orleans is an endowed institution, the operating expenses of which are paid by the city board of education. The endowment of this school may be used only for buildings and equipment.

NEW TYPES

One of the outstanding characteristics of semi-public vocational schools is their flexibility. In such institutions it is possible to carry on experimental work in vocational education in a way that would be difficult to realize in a public school. New types of organization for handling the instruction of individuals or groups can be worked out in an experimental way with a minimum of difficulty, and such schools or agencies are in a position to carry on original experiments with greater freedom than public institutions can carry them on. Much of the progress which has been made in the past ten years in vocational education has been, to a considerable extent, due to the experimental and developmental work carried on in such institutions as Dunwoody Institute, Minneapolis, as well as the more progressive public vocational schools.

For example, the organization of short unit courses, methods of individual instruction, methods of organizing trade instruction so as to permit of individual progression, the organization of instruction so as to make it possible for a man to get the training he needs when he needs it and when he can profit by it to the greatest extent, and similar practices which have been widely adopted throughout the country were to a very considerable extent influenced by the experimental work conducted in these institutions.

Due to the fact that practically all of the institutions referred to above are dependent for students upon the degree to which students receive the kind of help and instruction which they need, they are placed in a position where it is absolutely necessary for them to shape their policies and procedure to meet the needs not only of young men who are preparing themselves for profitable entrance into industrial employment but for the needs of those who are already employed. While trade schools which are operated as a part of the public school program are to some extent subjected to this condition, private and semipublic institutions are subjected to it to a very much greater extent.

Trade extension courses for employed workers constitute the greater portion of the work of endowed and semi-public institutions although pre-employment and trade preparatory courses are important features of their programs.

GROUPS SERVED BY VOCATIONAL EDUCATION

By Frank Cushman

Chief, Trade and Industrial Education Service

THE TAUGHT

All those persons who are served by the program of vocational education as it has been developed in the United States may be classified in two principal groups as follows: (1) Youths; (2) Employed workers. For both of these groups vocational education may include any form of training which fits an individual for the successful pursuit of a gainful occupation, or which assists any individual already employed in a gainful occupation to improve himself in the practice of that occupation or to secure promotion therein.

VOCATIONAL TRAINING OF YOUTH

The group referred to in this section as youths may be understood to include persons between the ages of 16 and 21. While the National Vocational Education Act recognizes vocational education as beginning as early as the age of 14, experience has shown quite conclusively that efforts to promote the objectives of vocational education are most efficient when the work with the 14 to 16 year old group is directed principally toward vocational guidance, social adjustment, and other prevocational objectives.

At the age of 16 the majority of young people are ready to make an intelligent choice of an occupation and this choice is likely to be made intelligently in proportion as the individual has enjoyed an opportunity to acquire a large amount of information concerning occupations and the ways in which the work of the world is done. Much effective vocational guidance and social adjustment work is accomplished through the special type of organization known as the general continuation school referred to under I-2.

Vocational education dealing with persons between 16 and 21 years of age is carried on under three principal types of organization, as follows: 1, Full-time courses; 2, part-time courses; 3, evening courses.

Full-time courses are usually organized upon the assumption that a group of minors can be effectively prepared for entrance into profitable employment by spending one or more years in definite preparation for going to work at a chosen occupation. The full-time day school meets the needs of a certain number of young people who are face to face with the necessity for earning a living; but in many ways a full-time day vocational school is less efficient, from the standpoint of vocational education, than various forms of part-time education.

In the field of vocational agriculture the principal development has occurred in rural high schools where the full-time preëmployment course has been notably successful. Full-time courses in vocational home economics in high schools have, however, not developed to a degree comparable with the development of agriculture, the major emphasis in home economics having been placed upon the development of part-time and evening classes. The full-time day school enrollment in home economics is less than 15 per cent. of the total enrollment. In the field of trade and industrial education, full-time day trade schools have also constituted a very small part of the program, the enrollment in full-time schools being approximately 10 per cent. of the total enrollment in all forms of trade and industrial schools. Part-time schools enroll approximately 65 per cent. of the total number and evening schools 25 per cent.

Part-Time Courses.—The most satisfactory results have been secured in the field of apprenticeship for the skilled trades where work and study have been properly combined under a part-time plan. In many cases, plans which call for an equal division of time between work and school have been eminently satisfactory. In other cases apprentices attend part-time school from 4 to 8 hours each week, for the purpose of receiving definite instruction and training supplementary to their practical experience secured on the job. A very efficient part-time plan for apprenticeship provides for one full eight-hour day in school each two weeks during the entire period of apprenticeship.

Where conditions are such that it is not practicable to set up a part-time plan for apprenticeship the next best substitute is the evening school. Evening trade extension vocational classes are open to employed workers 16 years of age or over; hence this type of organization lends itself to certain apprenticeship plans.

Evening Courses.—In the field of vocational home economics, experience has indicated that the most effective work is done with women who are confronted with the problems of managing a home rather than with girls of high school age. The evening program in vocational home economics therefore has far exceeded the enrollment in other types of schools or classes.

While the percentage of the total number served in evening and part-time schools in vocational agriculture is small the work is rapidly expanding and increasing in scope.

VOCATIONAL EDUCATION FOR EMPLOYED WORKERS

"Camel Theory" of Education.—There are two principal theories of education which are at the present time widely accepted by different groups of people in the United States.

One of these theories is based upon the assumption that a person should enter school at an early age and continue in school without interruption until he or she has finished a four-year college or university course. This theory is based upon several hypotheses, among which may be mentioned:

(1) That a college or university training for every citizen is a desirable social objective.

(2) That the educative process should be continuous and that under no circumstances should a boy or girl permit his or her attention to be diverted from regular school work by entering a definite wage-earning occupation.

(3) That an education can be secured most advantageously by devoting approximately sixteen years of one's life to school activities as a student prior to entering upon employment.

(4) That a system which is characterized by such a philosophy offers an equal opportunity for all youth.

This theory in substance amounts to an assertion that a young person should stay in school or college until his "intellectual hump" can be assumed to hold all of the knowledge which he will need to carry him across the desert of life. This theory almost completely ignores the educational value of work, as well as the psychological fact that the learning process is not complete until the learner makes some concrete applications of the principles covered by the instruction.

Apprentice Theory of Education.—A second theory is based upon the following assumptions:

(1) That training which includes only standard high school and college work does not supply the kind of education which most people need.

(2) That honest work has a great educational value, and should be utilized for its educational value throughout the period of attendance at high school and college.

(3) That all of one's education cannot be secured in school and college prior to engaging in useful and practical work.

(4) That much of the instruction and training in high school and college is meaningless to many students and is of no permanent value to them because they are unable to apply what they are taught in any definite way. Through lack of experience they fail to understand thoroughly what they are trying to learn.

(5) That a system which provides *identity* of opportunity for all does not provide *equality* of opportunity, and that the existing system of education provides a superior opportunity for the prospective professional man and a very limited opportunity for those who will engage in the ordinary occupations which must be carried on if society is to continue to exist.

This theory holds that the best results in education can be secured by the proper apportionment of work and study throughout the period of high school and college training with opportunity for application of the principles and the subject matter taught in the class. It also holds that opportunities should be provided for all persons, regardless of their age, to secure such instruction and training as they may need at any given period of their lives. It recognizes that only a small portion of one's education is secured in school or college, and that the educative process is, or should be, continuous throughout the period of life for the normal person. It discounts the value of a lot of undigested and unassimilated information received prior to getting a job. The proponents of this theory boldly assert that this is the only plan thus far formulated which offers equal educational opportunity to all and sets up a situation whereby democracy in education can be realized.

Schools for Employed Workers.—The whole program of vocational education for adult workers is justified if one accepts the apprentice theory of education. Under the "camel theory" educational opportunities, except for the selected few, are limited. Under the apprentice theory no limit is placed upon educational opportunities which may be provided for any citizen, except his desire to avail himself of those opportunities.

In general, it may be stated that vocational education for employed workers has two principal objectives, as follows:

(1) To enable individuals to become more efficient on their present jobs.

(2) To enable persons to qualify for advancement and promotion in their selected occupations.

Group Characteristics. — Persons who are attracted toward leisure time classes for either of the purposes previously discussed exhibit certain characteristics, among which may be mentioned:

(1) They usually know what they want. They are not particularly interested in courses of a general character but rather in specific instruction and training regarding some of their every-day problems.

(2) They have performed a full day's work, as a rule, before coming to school. Their attendance is an indication that they have a certain amount of ambition to get ahead. They are, therefore, characterized by a certain degree of earnestness and legitimate ambition.

(3) They usually want technical instruction rather than shop practice. This is perfectly natural inasmuch as most of them have a sufficient opportunity in connection with their daily work to learn the manipulative process of their trade. It is not at all common, however, for a man in the shop or a man working at an outside building trade to have an opportunity on the job to learn the technical aspects of his trade.

Diversity of the Work.—The program for employed workers has developed and expanded during the past seven years until the principal classes of employed workers are served to some extent. A list of 134 sample trade extension courses was recently prepared by the Federal Board for Vocational Education, and it was clearly shown that all of the principal groups of industrial occupations have been reached to a greater or less extent.

Foreman Training.—One important phase of occupational extension education is that form of foreman training which is conducted by some public or quasi public agency.

The public program of vocational education takes cognizance of the fundamental fact that industry cannot be used successfully as an educational agency for the young worker; and that consequently no apprenticeship scheme can succeed, except as the men with whom the young worker is most constantly in contact, the man who has direct control over him and his activities while at work, is able and willing to make of industry an educational agency, and intelligent enough to do it.

So, while the foreman himself may be an object of interest to local, State, and Federal educational authorities as a worker who needs to be helped to do his work well and to prepare for the next step, he becomes doubly an object of interest as a worker who has control over the vocational educational destinies of a large number of other workers.

Federal Aid.—The Federal Board for Vocational Education, as one means of promoting the progress of vocational education in the States has adopted the plan of conducting demonstration foreman training conferences or classes in plants at various points throughout this country in cooperation with representatives of State departments of vocational education, of teacher-training institutions, and of interested firms.

Foremen's conferences are round-table gatherings of foremen who are led to describe and discuss their own industrial experience, as foremen, and through the discussion to develop underlying principles, effective methods, and sound practices in dealing with their problems. A series of conferences in any plant should result in better working relationship between the departments and between the foremen and his subordinates and superiors.

Every foreman should be assisted to realize the educational problem in its relation to the work of the plant and of the industry, and to visualize himself primarily in the light of an instructor.

Most important of all, however, the conference discussion should be directed straight toward the determination of the permanent training program necessary to meet the needs of the industry, whether the program decided upon shall be limited to the foreman's own immediate instructional work with those under him, or extend to an organized plant program or to a coöperative arrangement between the industry and the public schools.

PURPOSES OF VOCATIONAL EDUCATION

By M. M. Proffitt

Specialist, United States Bureau of Education

Specific Training.—This discussion will be limited to specific courses and activities that are directly or indirectly contributing factors to the development of an efficient vocational program. The values of manual arts courses, for any other purpose than the contributions they can make to the later vocational courses, will not here be considered. Nevertheless, vocational education is very definite in its objectives and is clearly defined as to its purpose. Specifically, its purpose is to afford training that will prepare the individual for entrance upon some definite occupation.

In manual courses not of a strictly vocational type, great confusion exists as to objectives, specific courses, and types of projects. The terms "manual training," "manual arts," "practical arts," and "industrial arts" have been variously used. The useful term "prevocational education" is often used to connote any or all manual courses offered earlier in the curriculum than the strict vocational courses.

Love of Manipulation.—The essential characteristic of real vocational work is the opportunity it offers the individual for expressing himself freely in media of the common materials, such as wood and metal, stone or concrete, the expression being the result of manipulative operations and processes performed upon the material. Such work is psychological, being an appeal to the creative instinct. The desire to manipulate is, in origin, a tendency to manipulate things, whether by creating or destroying. The individual desires to see a change take place in "something" because he has altered that "something." Experience easily teaches the value of creating as opposed to destroying. The desire to manipulate things in a way that will be of use becomes a learned tendency. Manual arts courses of all types take advantage of this desire to manipulate.

Fields of Creation.—Individuals will vary in this tendency to manipulate, both as to the degree to which this trait is possessed and as to the nature of the object which the individual desires to manipulate. Nowhere in the entire educational program is the psychology of individual differences more pronounced. Some like best to manipulate material things and to create articles from wood, metal, stone, etc., while others desire to work with symbols and abstract ideas, and to create things which are largely thought products—the result of the development of ideas rather than of materials. A third class desire to direct the actions of other individuals, to assume leadership over men. These characteristic tendencies are in line with individual aptitudes and interests and are significant of their existence. The first class requires those qualifications necessary for success in the normal vocations found in the trades and industries, commerce and transportation, agriculture, and home making. The second class exhibits the qualifications necessary for success in the professional vocations, such as law, medicine, and the ministry.

Differentiation of Interest.—Any of the forms of manual arts are suited to a program of vocational education, the avowed purpose of which is definitely to prepare individuals for entrance upon specific occupations. Any of them aid the general education program in discovering individual aptitudes and interests, indicative of traits desirable for further development and refinement. As experience and practice forward these manifested interests, they will become more refined, and consequently more useful indices for the educational and vocational guidance of the individual. For example, the early manual training work of the grades aims at self-expression through the acquisition of muscular control and the opportunities it offers for connected thinking. At first there may be no marked differences among the pupils as to abilities, in either the manipulative processes or the thought processes involved. Before the completion of the elementary school, individual differences will begin to appear between two great vocational groups, the one in which the mental processes predominate, the other in which manual processes predominate. The manual training work should give, by the end of the elementary school, some indication as to aptitudes and interests for work with tools.

High School Differentiation.—The manual and industrial arts courses in the high school offer the student experiences in finer and more complex manipulative processes. The shop courses are developed more nearly along occupational lines than were those of the grades. The shop jobs may be quite definitely characteristic of trade work; still the organization of the courses is for the purpose of furnishing some participating experiences in a variety of occupational jobs rather than giving related experiences in one occupation. In addition to any discovery of aptitudes and interests in doing work with tools in the elementary school, the high school student has experiences that may lead to the discovery of more specific capacities. He may find that he has more ability and greater interest in working with some particular tools and materials.

Prevocational Values.—The contribution made to a program of vocational education by work done in prevocational schools and classes is to be looked for in connection with the discovery of aptitudes and interests in the individual which will function. It is thus possible to try him out on each of the occupations in turn; resort must be had to some form of representative sampling.

Vocational Guidance.—Well-organized courses in the prevocational school, in which some representative work of some of the larger vocational groups, such as agriculture, trade and industries, commerce, and home making is given, will furnish a type of participating experiences that will be of value in preventing misfits in the vocational education program. The whole question of vocational guidance is a very difficult one, not only because of the great number of occupations to be considered, but also because of the changing interests of the individual with developing maturity and also to the changing nature of the occupation itself.

The function of the manual arts and prevocational courses in relation to the vocational education program is to act as a series of sieves, the first ones with very large meshes separating individuals on basis of characteristics of the largest general vocational groups; the next ones differentiating a little more closely as to vocational capacities; and so on down to the last, where the individuals are separated for specific occupational training.

OPPORTUNITIES OF VOCATIONAL TRAINING

By C. F. Klinefelter

Regional Agent, Federal Board for Vocational Education

STATE VOCATIONAL SCHOOLS

Evening Schools.—Evening schools and classes are intended for persons, 16 years of age and over, who are regularly employed in definite occupations. Class sessions are held outside of the regular working day, and the members of the class attend by sacrificing some of their leisure time. In view of the fact that evening occupational extension work for adults can be given most successfully by means of short unit courses, the work is occupational extension in character rather than occupational-changing training. So far as the public program is concerned, which is supported in part by Federal aid, no funds may be used for evening classes unless the work is occupational extension in character.

Instruction in evening classes is largely concerned with the technical and theoretical side of the occupation, rather than with manipulative training. In certain cases, however, a short unit class may be organized to give manipulative training on a machine or process, in advance of the present manipulative work of the class members, in order to prepare them for advancement in the occupation. Experience has demonstrated that teachers of evening classes for adult workers must command the respect of their groups as occupational experts, and that technically trained teachers, without satisfactory occupational experience do not usually hold the interest of adult workers enrolled in their evening classes.

PART-TIME SCHOOLS

Part-time schools and classes are designed for young employed workers, between the ages of 14 to 18 years, although the upper limit has been construed to mean mental age, hence classes are in operation, under the part-time organization, for adult workers. Class sessions are held during the regular working day, on the employer's time. In the public program, which is aided from Federal funds, classroom instruction must extend over a minimum period of 144 hours per year. This training period may extend throughout the school year, for 4 or 8 hours per week, or it may be offered as a short, intensive program, as is the case with certain part-time classes for workers held during their dull season, when work at the occupation is slack, owing to climatic or other causes. The instruction offered in part-time schools may be of an occupational extension nature, it may be designed to prepare workers in juvenile "blind-alley" positions to transfer into other more permanent and desirable occupations, or it may be concerned primarily with giving further training in the fundamental arts which society deems essential, together with attention to assisting young workers to arrive at desirable adjustments toward their fellow workers, their employers, and society at large. In certain part-time schools provision is made to offer training and assistance to a type of worker commonly designated as the "in-and-outer." Here a worker, temporarily out of employment, enters the school, receives training until he is able to secure another position, perhaps on a higher level than before, when he goes back into full-time employment, until he feels the need of further training or again loses his position, when he returns to the school for further help.

ALL-DAY SCHOOLS

All-day vocational schools receive young people who have not yet gone to work and give them vocational training for specific occupations. The training in these schools includes instruction in the technical knowledge, practical operations, and the problems incident to each occupation, training in applying the technical knowledge to the practice of the occupation, and a certain small percentage of the time, usually 15 to 20 per cent., to general education subjects deemed necessary to round out the curriculum. All-day schools are operated for the same period of time as the regular schools in a given city, usually for nine months or more each year. Their courses are arranged to offer instruction for from 25 to 30 clock hours per week, depending upon the size of the city.

Separate Vocational Schools.—Certain States and cities maintain entirely separate all-day schools, having no connection with the regular high school program. In some instances such separate schools have an independent levying power for their funds, and are administered by a separate board or committee, distinct from the school board or committee.

The justification for these separate schools has been to avoid the friction and handicaps which are more or less inevitable in fitting such an organization into a regular school system primarily designed for the general, cultural education of its pupils.

Vocational Departments in High Schools.—The majority of the all-day schools or classes throughout the country are administered as separate departments in the regular high schools, as an integral part of the regular high school organization. While certain adjustments are necessary, and misunderstandings occasionally arise to cause temporary trouble, experience has fully demonstrated that it is entirely possible to offer distinct vocational courses in the regular high schools, without disruption to either interest. The vocational department in a high school issues a diploma from the vocational course, upon completion, just as a diploma is issued from the college preparatory course in the high school.

The vocational courses appeal to that class of high school students which is not interested in entering college but wishes to prepare to enter the practice of an occupation upon the completion of the high school course.

Special Schools.—Many private employers, firms, and associations carry on vocational training for their employees, by means of correspondence courses, evening classes, part-time classes, and short intensive full-time courses, conducted by their own training departments, or they negotiate with some outside training agency to come in and give their employees the training.

STATISTICS OF VOCATIONAL EDUCATION

By J. C. Wright

Director, Federal Board for Vocational Education

Table 1.—*Federal vocational education funds, by years*

Year ending June 30—	Amount of Federal Grant			
	Total	Agricultural Education	Industrial Education[1]	Teacher Training
1926 and annually thereafter[2]	$7,154,901.51	$3,021,987.39	$3,046,148.19	$1,086,765.93
1925	6,168,716.08	2,526,826.66	2,555,123.49	1,086,765.93
1924	5,190,448.02	2,036,502.12	2,067,179.97	1,086,765.93
1923	4,615,159.80	1,759,219.51	1,769,174.36	1,086,765.93
1922	4,120,833.72	1,510,993.69	1,523,074.10	1,086,765.93
1921	3,632,177.37	1,266,875.30	1,277,073.99	1,088,288.08
1920	3,051,919.01	1,022,637.75	1,032,875.96	996,405.30
1919	2,307,465.44	782,555.76	794,463.33	730,421.35
1918	1,655,586.72	547,027.79	564,444.89	544,114.04

[1] Including home economics and part-time general continuation education. Under the law not more than 20 per cent. of the Federal grant provided for "trade, home economics, and industrial education" may be expended for reimbursements on account of home economics education.

[2] For years subsequent to 1930, allotments based upon "the last preceding census" will be slightly different from those shown in this line, but will not vary from the figures given by more than a few thousands of dollars.

TABLE 2.—*Enrollment in federally aided schools (exclusive of teacher-training institutions), years ending June 30, 1918 to 1925*

Sex and Year	Enrollment							
	Total				Evening Schools Total	Part-time Schools Total	All-day Schools Total	Short Unit Course, Agricultural Schools
	Total	Agricultural[1]	Trade or Industrial	Home Economics				
Both sexes: 1925:	659,370	86,355	421,941	151,074	190,388	319,020	146,094	3,868

CHRONOLOGY FOR 1925.

JANUARY

1.—Postmaster General New announces departmental dismissals, suspensions, and resignations owing to propaganda for wage increase of workers.

2.—Senate committee presents Agricultural appropriation bill—$124,788,478, being $125,000 over the House total—and the Interior bill—$238,991,403, being $1,140,477 over the House total.

Attorney General Stone removes Assistant United States Attorney Walter D. Van Riper from office in New Jersey.

With the return of the "exiled" Republican Senators in Rhode Island the General Assembly ends the longest session ever held in the United States—one year.

Two hundred eighty-seven persons are saved from the Clyde liner Mohawk, burned at sea and scuttled in Delaware Bay.

Fascista Government in Italy begins its suppression of Communist journals, seizing offices in Rome, Naples, Genoa, and Turin.

Spain completes evacuation of 4,000 sq. miles of territory in Morocco and reduces effectives from 150,000 to 100,000.

3.—New York stock market breaks all trading records for 18 years with half-day transactions in 1,474,750 shares.

In Italian Chamber Premier Mussolini declares that he will crush all anti-Fascismo opposition within 48 hours.

5.—Four Governors are inaugurated—Mrs. Nellie T. Ross, the first woman governor in American history, at Cheyenne, Wyo., George H. Dern of Utah, Arthur G. Sorlie of North Dakota, and George W. P. Hunt of Arizona.

Harlan F. Stone is nominated Supreme Court Justice by President Coolidge in succession to Associate Justice Joseph McKenna, who resigns after 27 years of service.

In Italy former Premiers Giolitti, Orlando, and Salandra attempt to maintain an "official" Opposition in the Chamber and force two Liberal Ministers to resign from the Fascista Government.

6.—The Senate supports the President's veto of the Postal Salary Increase bill—55 to 29—the Republican vote of 28 with the vote of Senator Dial (Dem., S. C.) preventing the two-thirds vote necessary to override the veto.

President Coolidge decides not to call a conference of Governors for the purpose of furthering the Child Labor Amendment to the Constitution.

Germany protests to the Allies that the failure of the British to evacuate the Cologne bridgehead is a breach of the Versailles Treaty.

In Albania Ahmed Zogu Bey succeeds Bishop Noli as Premier.

7.—The Senate Appropriation Committee reports that, except for the Florida, the capital ships are on the 5-5-3 basis, and the Naval appropriation bill carrying $289,000,000.

Gov. Smith, in opening the New York legislature, asks non-partisan consideration of State problems, continuance of the 25 per cent. income tax reduction, and increased application of water power to public utilities.

Paol Loebe, a Socialist, is elected President of the German Reichstag, disrupting Nationalist plans.

8.—President Coolidge is announced by Secretary Wilbur to be opposed to gun elevation, although contrary to expert opinion, which is that it would be no violation of the naval disarmament treaty.

John H. Trumbull succeeds Hiram Bingham as Governor of Connecticut.

The Child Labor Amendment to the Federal Constitution is ratified by the California legislature: the Senate, 36 to 3; the House, 69 to 9.

9.—The War Supply bill carrying $331,000,000, of which $40,000,000 is for rivers and harbors, is passed by the House.

10.—Secretary Hughes resigns as head of the State Department and Frank B. Kellogg, Ambassador at London, is nominated to succeed him.

American war claims are adjusted by Col. Logan and the British Chancellor of the Exchequer under the Dawes plan: the bill of $255,000,000 for the American army of occupation and that of $350,000,000 for war-damage.

11.—In China, Gen. Chi Hsieh-yuan usurps the Peking administration in the native quarter of Shanghai.

Of the German total of reparation payments, amounting to 286,263,447 gold marks, France has received 113,600,000 and England 65,800,000.

12.—Jonathan M. Davis, the retiring Democratic Governor of Kansas, is arrested charged with accepting bribes for pardons.

In Italy Premier Mussolini, in opening the Chamber, introduces a bill to wipe out Freemasonry as a secret society and forbidding membership therein of Government employes.

14.—The Senate having substituted the Jones amendment for the Underwood Muscle Shoals bill and then displacing the former by the Norris government-operation amendment, on Jan. 13, now adopts the Underwood measure, which provides for the leasing of Government plants for manufacturing nitrates and the production of electric power: 50 to 30.

The McFadden bill, revising the banking laws, with the Hull amendments for branch banking is passed by the House.

The Child Labor amendment is defeated in the South Carolina legislature.

An international financial agreement is signed at Paris by Belgium, France, Great Britain, Italy, Japan, the United States, Brazil, Greece, Portugal, Rumania, Yugoslavia, and Czechoslovakia, which among other things fixes the Ruhr occupation profit at 800,000,000 gold marks.

15.—Major Gen. Robert Lee Bullard retires as commander of the Second Corps, with headquarters at Governor's Island, N. Y., and is succeeded by Maj. Gen. Charles P. Summerall. Gen. Bullard entered the service in 1901.

16.—Texas Rangers, famous in the history and fiction of the Mexican border, are declared to be an unconstitutional organization by a San Antonio court and surrender their arms.

John D. Rockefeller, Jr., donates $1,600,000 toward reconstruction of Tokio Imperial library, the Japanese Government having appropriated a similar amount.

17.—The House adopts Urgent Deficiency bill reported by conference, carrying $150,000,000 for tax refunds, $3,501,200 for Dam No. 2, Muscle Shoals, and $3,000,000 for Inland Waterways stock purchase.

In Italy the Chamber adopts Mussolini's electoral reform bill—268 to 19—and adjourns till Feb. 15.

18.—In Germany the Luther Cabinet decrees resumption of the eight-hour law on April 1.

19.—The Senate defeats a measure to provide money for the elevation of naval guns.

Secretary Hughes makes formal criticism of Paris agreement of Jan. 14 to the effect that it "neither surrenders nor modifies any treaty right of the United States."

20.—The Senate adopts majority report of investigating committee condemning "Teapot Dome" leases: 40 to 30.

Mrs. Miriam Amanda Ferguson is inaugurated Governor of Texas.

21.—The House adopts the Cramton resolution authorizing the Secretary of War to restore immediately the Robert E. Lee mansion in Arlington Cemetery.

British dreadnought Monarch is sunk under terms of Washington pact.

22.—President Coolidge signs the Treasury Post Office bill carrying $760,000,000.

Senator Borah (Rep., Id.) opens his campaign against showing any sentimental partiality toward the French war debt.

In Germany, the Luther Cabinet supported by Nationalists, Popularists, Economic Unionists, Bavarian People's party, and Catholic Centrists receives a vote of confidence in the Reichstag: 246 to 160.

Costa Rica resigns as a member of the League of Nations.

23.—Senator Bruce (Dem., Md.) answers Senator Borah's French war debt speech of the day before.

In Chile the Alamirabo Government is deposed by the military junta and President Alessandri is recalled.

24.—President Coolidge, in an address before the Women's Conference on Cause and Cure of War, favors joining the World Court.

Klan leader S. G. Young is killed by Ora Thomas, deputy sheriff of Herrin, Ill., who is, in turn, killed by Klansmen.

Total solar eclipse is observed from Minnesota to beyond the North Atlantic States.

Herbert H. Asquith is made Earl of Oxford and Asquith with seat in the House of Lords.

25.—Representatives of New York, New Jersey, and Pennsylvania sign compact for utilizing Delaware River water at an expenditure of $500,000,000 within the next century and guaranteeing a supply of a billion gallons a day.

Foreign securities valued at $1,268,438,394 were purchased in the United States in 1924, according to a Department of Commerce report.

Tut-ankh-amen's tomb, after being closed a year, is reopened by Howard Carter in Egypt.

26.—President Coolidge, in address to budget organization, requests reduction of national expenditures by three billion—the first of his economy speeches.

Child Labor amendment is rejected by the legislatures of Oklahoma, Kansas, Ohio, and Texas, and by the North Dakota Senate.

Everett Sanders succeeds C. Bascom Slemp as secretary to President Coolidge.

Cathedral of St. John the Divine, New York City: contract is let for building nave at a cost of $5,900,000.

27.—The Smith-Hoch resolution directing the Interstate Commerce Commission to regard farm products as basic industry in adjusting freight rates is adopted by the Senate.

28.—Child Labor amendment is ratified by New Mexico House—40 to 8—and defeated by those of Delaware and Washington.

29.—Col. William Hayward resigns as U. S. Attorney for the district of New York, and is succeeded by Emory R. Buckner, on Jan. 31.

Premier Herriot's foreign policy receives vote of confidence in the French Chamber: 541 to 32.

30.—The Senate passes the Postal Pay and Rate Increase bill: 70 to 8.

In the case of former Assistant Secretary of War Benedict Crowell, Attorney General Stone withdraws appeal on the ground of insufficient indictment.

Thomas B. Felder and Gaston B. Means are convicted by New York Federal jury on charge of conspiring to obstruct justice and are each fined $10,000, with an additional two years' imprisonment for Means.

In Russia, Frunse succeeds Trotsky as Commissar for Army and Navy.

31.—Patriarch Constantinos of the Greek Orthodox Church is deported by the Turkish authorities from Constantinople.

FEBRUARY

1.—The Agricultural Conference recommends a special Federal agency to represent the small shippers of farm products.

In China there is a conference of 146 military leaders at Peking, where the Moscow program and the anti-foreign policy are discussed.

2.—The House passes six-year building program bill—243 to 116—but the $150,000,000 estimate is not appropriated.

The Air Mail bill, promoting commercial aviation by civil means, is signed by the President.

In Nome, Alaska, a diphtheria epidemic is broken by dog-sleds bringing antitoxin from Nenana, 650 miles.

Suppression of French Embassy at the Vatican is voted by the French Chamber, 315 to 250, but on account of the special status of Alsace-Lorraine an agency must be maintained there.

Don Gelasio dei Principi di Caetani is succeeded by Giacomo de Martino as Italian Ambassador at Washington.

3.—A resolution favoring the World Court is reported favorably by the House Foreign Affairs Committee.

The Child Labor amendment is defeated by the Connecticut Senate—33 to 1—and by the Nevada Assembly: 19 to 18.

Discovery of the "missing link" is announced by Prof. Raymond Dart at Johannesburg, South Africa. At Ur, the University of Pennsylvania expedition unearths a library with Chaldean tablets said to date from 2500 B.C.

4.—Col. Charles R. Forbes, former Director of the Veterans' Bureau, and John W. Thompson, contractor, are convicted by a Chicago Federal court and each sentenced to two years and a $10,000 fine on charge of conspiring to defraud the Government in hospital contracts.

Polish debt settlement with the United States is ratified by the Senate at Warsaw.

5.—Attorney General Stone's appointment to the Supreme Court is confirmed by the Senate: 71 to 6.

6.—Brig. Gen. William Mitchell criticizes Navy and Army aviation before the House Air Service committee.

John D. Rockefeller donates $500,000 to the Cathedral of St. John the Divine.

In Nepal, northern India, the Maharajah Tribhuba Bir Bikram abolishes slavery, freeing 51,419.

7.—The $150,000,000 highway appropriation bill with Senate amendments approved by the House goes to the President.

8.—Mayor Hylan of New York is blamed and the Transit Commission is exculpated in report of Supreme Court Justice John V. McAvoy.

Japanese battleship Tosa is sunk under Washington disarmament treaty.

10.—Three treaties are ratified by the Senate: the German Commercial, the Palmas Island accord with Holland, and the Rumanian extradition.

Building bridge laws for the promotion of Hudson River traffic to New York are passed by New Jersey legislature.

A germicide for kidney germs, called hexylresorcinol, is announced by Dr. Veader Leonard of Johns Hopkins School of Hygiene.

11.—The election of Calvin Coolidge as President and Charles G. Dawes as Vice-President are formally declared by Congress after counting the electoral votes; Coolidge's popular plurality is 7,403,229; his electoral majority, 233.

Naval Appropriation bill is signed by the President calling, incidentally, for a second disarmament conference.

International Opium Conference at Geneva, from which the United States delegates withdrew on Feb. 6 and the Chinese delegates the next day because producing countries declined supervision of output, signs convention.

12.—The Child Labor amendment is rejected by the Vermont House: 229 to 3.

A coal mine explosion kills 200 at Dortmund, the Ruhr.

13.—The Bulgarian designate Minister at Washington, Nicola Mileff, is assassinated in Sofia.

The Dyer China trade bill, passed by the House, is sent to the Senate.

14.—The President nominates Frank B. Kellogg Secretary of State, William M. Jardine Secretary of Agriculture, and George Parks Governor of Alaska.

In Italy the Senate passes the electoral bill: 214 to 58.

15.—A New York, New Haven & Hartford R. R. bond issue for $23,000,000 is oversubscribed without underwriters.

16.—The Senate confirms the nomination of Mr. Kellogg as Secretary of State and passes its own Postal Pay and Rate bill, wiping out House amendments.

16.—Aircraft Committee of the House hears testimony from naval and army officials and draws the conclusion that air defense is inadequate.

In Germany, the Luther Government asks for credits of $175,000,000 to Ruhr industrialists as indemnity for Franco-Belgian occupation.

17.—The Child Labor amendment is defeated by the Pennsylvania Senate: 43 to 4.

Dr. Wilhelm Marx accepts Premiership of Prussia.

18.—That the battleship is the final arbiter in naval warfare is held by report of the General Board of the Navy published by the President.
